

MPC5565 Microcontroller Reference Manual

This MPC5565 Reference Manual set consists of the following files:

- MPC5565 Reference Manual Addendum, Rev 1
- MPC5565 Microcontroller Reference Manual, Rev 2

MPC5565 Reference Manual Addendum

This errata document describes corrections to the *MPC5565 Preliminary Microcontroller Reference Manual*, order number MPC5565RM. For convenience, the addenda items are grouped by revision. Please check our website at <http://www.freescale.com/powerarchitecture> for the latest updates.

The current version available of the *MPC5565 Microcontroller Reference Manual* is Revision 1.0.

Table 1. MPC5565RM Rev 1.0 addendum (continued)

Location	Description																										
Section 9.2.2.13: eDMA Interrupt Request Register (EDMA_IRQRL)/ Page 9-17	In the second paragraph, remove the last line "without the need to perform a read-modify-write sequence to the EDMA_IRQRL".																										
Section 8.3: Initialization and Application Information/Page 8-14	<p>Replace the whole section with the following information: The Error Correction Code (ECC) is used to verify the contents of the internal SRAM and flash memories. This is done by generating ECC check bits. Typically ECC check bits are calculated on writes and then used on reads to detect and correct errors.</p> <ul style="list-style-type: none"> • SRAM—Eight ECC check bits for each 64-bit SRAM data doubleword. • Flash—Eight ECC check bits for each 64-bit flash data doubleword. <p>After Power on Reset (POR), the contents of internal SRAM is random and the corresponding ECC check bits are unknown. To prevent generating ECC errors during reads, an initialization routine must perform 64 bit writes to all SRAM locations. Because the flash module is non-volatile, the ECC check bits are calculated and stored when the flash is programmed. Transparent to the application, the ECC uses the check bits to automatically correct single-bit memory errors. Multi-bit memory errors are not correctable. If the ECC detects a multi-bit error, an exception is generated. The type of exception generated by a multi-bit error depends on the settings of the EE and ME in the Machine State Register (MSR), as shown in the following table. When error reporting is enabled, as long as its priority is 0, an interrupt request is generated to the interrupt controller (INTC) even though the INTC request is not serviced.</p> <div style="text-align: center;"> <p>MSR[EE] and MSR[ME] Bit Settings</p> <table border="1" data-bbox="501 905 1425 1178"> <thead> <tr> <th>Field</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>EE</td> <td>External interrupt enable. 0 External input interrupts disabled. 1 External interrupts enabled.</td> </tr> <tr> <td>ME</td> <td>Machine check enable. 0 Machine check interrupts disabled. Enters machine check. 1 Machine interrupts enabled.</td> </tr> </tbody> </table> </div> <p>A non-correctable data ECC error executes one of the following actions, regardless of whether non-correctable reporting is enabled:</p> <div style="text-align: center;"> <p>Non-correctable Data ECC States</p> <table border="1" data-bbox="529 1337 1398 1761"> <thead> <tr> <th>MSR[EE]</th> <th>MSR[ME]</th> <th>Access Type</th> <th>Result</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Instruction or data</td> <td>Enters checkstop state. Therefore, for future compatibility, the TLB entry covering the INTC_IACKR must be configured to be guarded.”</p>																																																																																																																																								
<p>Table 10-3. INTC Memory Map/Page 10-8</p>	<p>Add the following note at the end of this table: Note: To ensure compatibility with all PowerPC processors, the TLB entry covering the INTC memory map must be configured as guarded, both in software and hardware vector modes.</p> <ul style="list-style-type: none"> • In software vector mode, the INTC_IACKR must not be read speculatively. • In hardware vector mode, guarded writes to the INTC_CPR or INTC_EOIR complete before the interrupt acknowledge signal from the processor asserts. 																																																																																																																																								

Table 1. MPC5565RM Rev 1.0 addendum (continued)

Location	Description
<p>Table 10-9. MPC5565 Interrupt Request Sources/Page 10-23</p>	<p>Note: Update the note at the end of this table as follows: The INTC has no spurious vector support. Therefore, if an asserted peripheral or software settable interrupt request (whose PRI value in INTC_PSRn is higher than the PRI value in INTC_CPR) negates before the interrupt request to the processor for that peripheral or software settable interrupt request is acknowledged, the interrupt request to the processor still can assert or remain asserted for that peripheral or software settable interrupt request. If the interrupt request to the processor does assert or does remain asserted:</p> <ul style="list-style-type: none"> • The interrupt vector will correspond to that peripheral or software settable interrupt request. • The PRI value in the INTC_CPR will be updated with the corresponding PRI value in INTC_PSRn. <p>Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral or, alternatively, setting its mask bit has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.</p>
<p>Section 10.4.2.1.4, "Priority Comparator Submodule"/ Page 10-25</p>	<p>Add the following paragraph to this section: One consequence of the priority comparator design is that once a higher priority interrupt is captured, it must be acknowledged by the CPU before a subsequent interrupt request of even higher priority can be captured. For example, if the CPU is executing a priority level 1 interrupt, and a priority level 2 interrupt request is captured by the INTC, followed shortly by a priority level 3 interrupt request to the INTC, the level 2 interrupt must be acknowledged by the CPU before a new level 3 interrupt will be generated.</p>
<p>Section 10.5.5.2, "Ensuring Coherency"/ Page 10-32</p>	<p>Move the content of this section under a new heading Section 10.5.5.2.1, "Interrupt with Blocked Priority". Add the following paragraph to this section: Section 10.5.5.2.2: Raised Priority Preserved Before the instruction after the GetResource system service executes, all pending transactions have completed. These pending transactions can include an ISR for a peripheral or software settable interrupt request whose priority was equal to or lower than the raised priority. Also, during the epilog of the interrupt exception handler for this preempting ISR, the raised priority has been restored from the LIFO to PRI in INTC_CPR. The shared coherent data block now can be accessed coherently. Following figure shows the timing diagram for this scenario, and the table explains the events. The example is for software vector mode, but except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.</p>

Location	Description
Section 6.3.1.118 “Pad Configuration Register 218 (SIU_PCR218)”	<ul style="list-style-type: none"> • Change PA field from two bits to one bit • Figure 6-119: Change note 2 to “... set the PA field to 0b0.” • Table 6-119. PCR218 “PA Field Definition” change as shown below: 0b0 FCK 0b1 AN[15]
Section 11.3.1.1 Synthesizer Control Register (FMPLL_SYNCR)	<p>Changed the last note in PREDIV field description from “To use the 8-20 MHz OSC, the PLL predivider must be configured for divide-by-two operation by tying PLLCFG[2] low (set PREDIV to 0b000).” to “When using an 8 to 20 MHz reference clock (crystal or external clock), PLLCFG[2] should be set low for devices that have a PLLCFG[2] pin. This sets the default predivider (PREDIV) to 0b000. To use a crystal or external reference greater than 20 MHz (up to 40 MHz), the PLL predivider must be configured for divide-by-2 operation by setting PLLCFG[2] high. This sets the default predivider (PREDIV) to 0b001. After reset, PREDIV must not be configured to a value less than divide-by-2 (with a 40 MHz crystal/reference).”</p>

2 Revision history

Table 2 provides a revision history for this document.

Table 2. Revision history

Revision	Substantive changes	Date of release
1.0	<ul style="list-style-type: none"> Initial release. Corrected errors in chapter 12, "External Bus Interface (EBI)." 	10/2009
2.0	<ul style="list-style-type: none"> Corrected error in chapter 9, "Enhanced Direct Memory Access (eDMA)." Corrected errors in chapter 10, "Interrupt Controller (INTC)." Corrected errors in chapter 5, "Peripheral Bridge (PBRIDGE A and PBRIDGE B)." Corrected peripheral bridge name errors in appendix A, "MPC5565 Register Map." Corrected unified channel block diagram in chapter 16, "Enhanced Modular Input/Output Subsystem (eMIOS)." Corrected the table shown in EMIOS_CCRn: DMA bit description. Clarified the description in Section 9.4.1, "eDMA Microarchitecture". Clarified the description in Section 9.3.1.13, "eDMA Interrupt Request Registers (EDMA_IRQRL). Corrected the ECSM initialization information in Section 8.3: Initialization and Application Information. Clarified the code sequence in Section 10.5.5.2: Ensuring Coherency. Clarified note in the INTC Interrupt Acknowledge Register . Added a note in the INTC Memory Map table. Clarified note at the end of the MPC5565 Interrupt Request Sources table. Added a paragraph to the Section 10.4.2.1.4, "Priority Comparator Submodule". Updated Section 10.5.5.2, "Ensuring Coherency". Corrected table "PCR218 PA Field Definition" and figure "AN[15]_FCK Pad Configuration Register (SIU_PCR218)" and update note 2. Updated the last note in PREDIV field description of Synthesizer Control Register (FMPLL_SYNCNCR). 	04/2012

How to Reach Us:

Home Page:

www.freescale.com

E-mail:

support@freescale.com

USA/Europe or Locations Not Listed:

Freescale Semiconductor
Technical Information Center, CH370
1300 N. Alma School Road
Chandler, Arizona 85224
+1-800-521-6274 or +1-480-768-2130
support@freescale.com

Europe, Middle East, and Africa:

Freescale Halbleiter Deutschland GmbH
Technical Information Center
Schatzbogen 7
81829 Muenchen, Germany
+44 1296 380 456 (English)
+46 8 52200080 (English)
+49 89 92103 559 (German)
+33 1 69 35 48 48 (French)
support@freescale.com

Japan:

Freescale Semiconductor Japan Ltd.
Headquarters
ARCO Tower 15F
1-8-1, Shimo-Meguro, Meguro-ku,
Tokyo 153-0064, Japan
0120 191014 or +81 3 5437 9125
support.japan@freescale.com

Asia/Pacific:

Freescale Semiconductor Hong Kong Ltd.
Technical Information Center
2 Dai King Street
Tai Po Industrial Estate
Tai Po, N.T., Hong Kong
+800 26668334
support.asia@freescale.com

For Literature Requests Only:

Freescale Semiconductor Literature Distribution Center
P.O. Box 5405
Denver, Colorado 80217
1-800-441-2447 or 303-675-2140
Fax: 303-675-2150

Information in this document is provided solely to enable system and software implementers to use Freescale Semiconductor products. There are no express or implied copyright licenses granted hereunder to design or fabricate any integrated circuits or integrated circuits based on the information in this document.

Freescale Semiconductor reserves the right to make changes without further notice to any products herein. Freescale Semiconductor makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Freescale Semiconductor assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters that may be provided in Freescale Semiconductor data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals", must be validated for each customer application by customer's technical experts. Freescale Semiconductor does not convey any license under its patent rights nor the rights of others. Freescale Semiconductor products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Freescale Semiconductor product could create a situation where personal injury or death may occur. Should Buyer purchase or use Freescale Semiconductor products for any such unintended or unauthorized application, Buyer shall indemnify and hold Freescale Semiconductor and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Freescale Semiconductor was negligent regarding the design or manufacture of the part.

Chapter 1 Introduction

1.1	Overview	1-1
1.2	Features	1-3
1.3	MPC5500 Family Comparison	1-9
1.4	Detailed Features	1-11
1.4.1	e200z6 Core Overview	1-11
1.4.2	System Bus Crossbar Switch (XBAR)	1-12
1.4.3	Enhanced Direct Memory Access (eDMA)	1-12
1.4.4	Interrupt Controller (INTC)	1-13
1.4.5	Frequency Modulated Phase-Locking Loop (FMPLL)	1-13
1.4.6	External Bus Interface (EBI)	1-13
1.4.7	Calibration Bus Interface (CBI)	1-13
1.4.8	System Integration Unit (SIU)	1-14
1.4.9	Error Correction Status Module (ECSM)	1-14
1.4.10	Flash Memory	1-14
1.4.11	Cache	1-14
1.4.12	Static RAM (SRAM)	1-15
1.4.13	Boot Assist Module (BAM)	1-15
1.4.14	Enhanced Management Input/Output System (eMIOS)	1-15
1.4.15	Enhanced Time Processing Unit (eTPU)	1-15
1.4.16	Enhanced Queued A/D Converter (eQADC)	1-16
1.4.17	Deserial/Serial Peripheral Interface (DSPI)	1-16
1.4.18	Enhanced Serial Communications Interface (eSCI)	1-16
1.4.19	Flexible Controller Area Network (FlexCAN)	1-16
1.4.20	Nexus Development Interface (NDI)	1-17
1.4.21	JTAG Controller (JTAGC)	1-17
1.5	MPC5500 Family Memory Map	1-17
1.6	Multi-Master Operation Memory Map	1-21
1.7	Document Revision History	1-22

Chapter 2 Signal Description

2.1	Block Diagram	2-1
2.2	External Signal Descriptions	2-3
2.3	Detailed Signal Description	2-18
2.3.1	Reset and Configuration Signals	2-18
2.3.2	External Bus Interface (EBI) Signals	2-19
2.3.3	Nexus Signals	2-23
2.3.4	JTAG Signals	2-24
2.3.5	Controller Area Network (FlexCAN) Signals	2-25
2.3.6	Serial Communication Interface (eSCI) Signals	2-25
2.3.7	Deserial/Serial Peripheral Interface (DSPI) Signals	2-26
2.3.8	Enhanced Queued A/D Controller (eQADC) Signals	2-29

2.3.9	Enhanced Time Processing Unit (eTPU) Signals	2-32
2.3.10	Enhanced Management Input/Output System (eMIOS) Signals	2-37
2.3.11	General Purpose Input / Output (GPIO) Signals	2-38
2.3.12	Calibration Bus Signals	2-39
2.3.13	Clock Synthesizer Signals	2-40
2.3.14	Power / Ground Signals	2-41
2.3.15	I/O Power and Ground Segmentation	2-42
2.4	eTPU Pin Connections and Serialization	2-45
2.4.1	ETPUA[0:15]	2-45
2.4.2	ETPUA[16:31]	2-47
2.5	eMIOS Pin Connections and Serialization	2-48
2.6	Document Revision History	2-50

Chapter 3 e200z6 Core Complex

3.1	Introduction	3-1
3.1.1	Block Diagram	3-1
3.1.2	Overview	3-2
3.1.3	Features	3-3
3.1.4	Microarchitecture Summary	3-5
3.2	Core Registers and Programmer's Model	3-6
3.2.1	Power Architecture Registers	3-8
3.2.2	Core-Specific Registers	3-11
3.2.3	e200z6 Core Complex Features Not Supported in the Device	3-12
3.3	Functional Description	3-13
3.3.1	Memory Management Unit (MMU)	3-13
3.3.2	L1 Cache	3-22
3.3.3	Interrupt Types	3-29
3.3.4	Bus Interface Unit (BIU)	3-31
3.3.5	Timer Facilities	3-31
3.3.6	Signal Processing Extension APU (SPE APU)	3-32
3.3.7	SPE Programming Model	3-32
3.4	External References	3-33
3.5	Power Architecture Instruction Extensions – VLE	3-33
3.6	Document Revision History	3-34

Chapter 4 Reset

4.1	Introduction	4-1
4.2	External Signal Description	4-2
4.2.1	Reset Input ($\overline{\text{RESET}}$)	4-2
4.2.2	Reset Output ($\overline{\text{RSTOUT}}$)	4-2
4.2.3	Reset Configuration ($\overline{\text{RSTCFG}}$)	4-3
4.2.4	Weak Pull Configuration (WKPCFG)	4-3

4.2.5	Boot Configuration (BOOTCFG[0:1])	4-3
4.3	Memory Map/Register Definition	4-3
4.3.1	Register Descriptions	4-3
4.4	Functional Description	4-6
4.4.1	Reset Vector Locations	4-6
4.4.2	Reset Sources	4-7
4.4.3	Reset Configuration and Configuration Pins	4-11
4.4.4	Reset Configuration Timing	4-16
4.4.5	Reset Flow	4-18
4.5	Document Revision History	4-20

Chapter 5 Peripheral Bridge (PBRIDGE_A, PBRIDGE_B)

5.1	Introduction	5-1
5.1.1	Block Diagram	5-1
5.1.2	Overview	5-1
5.1.3	Features	5-3
5.1.4	Modes of Operation	5-3
5.2	External Signal Description	5-3
5.3	Memory Map and Register Definitions	5-4
5.3.1	Register Descriptions	5-5
5.4	Functional Description	5-11
5.4.1	Access Support	5-11
5.4.2	Peripheral Write Buffering	5-11
5.4.3	General Operation	5-13
5.5	Document Revision History	5-14

Chapter 6 System Integration Unit (SIU)

6.1	Introduction	6-1
6.1.1	Block Diagram	6-2
6.1.2	Overview	6-3
6.1.3	Modes of Operation	6-3
6.2	External Signal Description	6-4
6.2.1	Detailed Signal Descriptions	6-4
6.3	Memory Map and Register Definition	6-9
6.3.1	Register Descriptions	6-10
6.4	Functional Description	6-114
6.4.1	System Configuration	6-114
6.4.2	Reset Control	6-115
6.4.3	External Interrupt	6-115
6.4.4	GPIO Operation	6-116
6.4.5	Internal Multiplexing	6-116
6.5	Document Revision History	6-120

Chapter 7 Crossbar Switch (XBAR)

7.1	Introduction	7-1
7.1.1	Block Diagram	7-1
7.1.2	Overview	7-2
7.1.3	Features	7-2
7.1.4	Modes of Operation	7-3
7.2	Memory Map and Register Definition	7-3
7.2.1	Register Descriptions	7-4
7.3	Functional Description	7-8
7.3.1	Overview	7-8
7.3.2	General Operation	7-8
7.3.3	Master Ports	7-9
7.3.4	Slave Ports	7-9
7.3.5	Priority Assignment	7-10
7.3.6	Arbitration	7-10
7.4	Document Revision History	7-12

Chapter 8 Error Correction Status Module (ECSM)

8.1	Introduction	8-1
8.1.1	Overview	8-1
8.1.2	Features	8-2
8.2	Memory Map and Register Definition	8-2
8.2.1	Register Descriptions	8-3
8.3	Initialization and Application Information	8-14
8.4	Document Revision History	8-15

Chapter 9 Enhanced Direct Memory Access (eDMA)

9.1	Introduction	9-1
9.1.1	Overview	9-1
9.1.2	Features	9-2
9.1.3	Modes of Operation	9-3
9.2	Memory Map and Register Definition	9-4
9.2.1	Memory Map	9-4
9.2.2	Register Descriptions	9-6
9.3	Functional Description	9-28
9.3.1	eDMA Microarchitecture	9-28
9.3.2	eDMA Basic Data Flow	9-30
9.3.3	eDMA Performance	9-32
9.4	Initialization / Application Information	9-35
9.4.1	eDMA Initialization	9-35
9.4.2	DMA Programming Errors	9-37

9.4.3	DMA Request Assignments	9-38
9.4.4	DMA Arbitration Mode Considerations	9-39
9.4.5	DMA Transfer	9-41
9.4.6	TCD Status	9-44
9.4.7	Channel Linking	9-45
9.4.8	Dynamic Programming	9-46
9.5	Document Revision History	9-48

Chapter 10 Interrupt Controller (INTC)

10.1	Introduction	10-1
10.1.1	Block Diagram	10-1
10.1.2	Overview	10-2
10.1.3	Features	10-4
10.1.4	Modes of Operation	10-4
10.2	External Signal Description	10-6
10.3	Memory Map and Register Definition	10-8
10.3.1	Register Descriptions	10-9
10.4	Functional Description	10-14
10.4.1	Interrupt Request Sources	10-14
10.4.2	Priority Management	10-24
10.4.3	Details on Handshaking with Processor	10-26
10.5	Initialization/Application Information	10-28
10.5.1	Initialization Flow	10-28
10.5.2	Interrupt Exception Handler	10-28
10.5.3	ISR, RTOS, and Task Hierarchy	10-30
10.5.4	Order of Execution	10-31
10.5.5	Priority Ceiling Protocol	10-32
10.5.6	Selecting Priorities According to Request Rates and Deadlines	10-33
10.5.7	Software Settable Interrupt Requests	10-33
10.5.8	Lowering Priority Within an ISR	10-34
10.5.9	Negating an Interrupt Request Outside of its ISR	10-35
10.5.10	Examining LIFO contents	10-35
10.6	Document Revision History	10-36

Chapter 11 Frequency Modulated Phase Locked Loop and System Clocks (FMPLL)

11.1	Introduction	11-1
11.1.1	Block Diagrams	11-1
11.1.2	Overview	11-8
11.1.3	Features	11-8
11.1.4	FMPLL Modes of Operation	11-9
11.2	External Signal Description	11-12

11.3	Memory Map/Register Definition	11-12
11.3.1	Register Descriptions	11-12
11.4	Functional Description	11-19
11.4.1	Clock Architecture	11-19
11.4.2	Clock Operation	11-21
11.4.3	Clock Configuration	11-24
11.5	Document Revision History	11-33

Chapter 12 External Bus Interface (EBI)

12.1	Introduction	12-1
12.1.1	Block Diagram	12-2
12.1.2	Overview	12-3
12.1.3	Features	12-4
12.1.4	Modes of Operation	12-5
12.2	External Signal Description	12-7
12.2.1	Detailed Signal Descriptions	12-8
12.2.2	Signal Function and Direction by Mode	12-11
12.3	Memory Map and Register Definition	12-13
12.3.1	Register Descriptions	12-14
12.4	Functional Description	12-21
12.4.1	External Bus Interface Features	12-21
12.4.2	External Bus Operations	12-26
12.5	Initialization and Application Information	12-61
12.5.1	Booting from External Memory	12-61
12.5.2	Running with SDR (Single Data Rate) Burst Memories	12-61
12.5.3	Running with Asynchronous Memories	12-62
12.5.4	Connecting an MCU to Multiple Memories	12-65
12.5.5	Dual-MCU Operation with Reduced Pinout MCUs	12-65
12.5.6	Summary of Differences from MPC5xx	12-67
12.6	Document Revision History	12-68

Chapter 13 Flash Memory

13.1	Introduction	13-1
13.1.1	Block Diagram	13-1
13.1.2	Overview	13-1
13.1.3	Features	13-3
13.1.4	Modes of Operation	13-3
13.2	External Signal Description	13-4
13.2.1	Voltage for Flash Only (V_{FLASH})	13-4
13.2.2	Program and Erase Voltage for Flash Only (V_{PP})	13-4
13.3	Memory Map/Register Description	13-4
13.3.1	Flash Memory Map	13-5

13.3.2	Register Descriptions	13-8
13.4	Functional Description	13-21
13.4.1	Flash Bus Interface Unit (FBIU)	13-21
13.4.2	Flash Memory Array: User Mode	13-24
13.4.3	Flash Memory Array: Stop Mode	13-35
13.4.4	Flash Memory Array: Reset	13-36
13.5	Revision History	13-37

Chapter 14 Internal Static RAM (SRAM)

14.1	Introduction	14-1
14.2	SRAM Operating Modes	14-1
14.3	External Signal Description	14-1
14.4	Register Memory Map	14-2
14.5	Functional Description	14-2
14.6	SRAM ECC Mechanism	14-2
14.6.1	Access Timing	14-3
14.6.2	Reset Effects on SRAM Accesses	14-4
14.7	Initialization and Application Information	14-4
14.7.1	Example Code	14-5
14.8	Document Revision History	14-5

Chapter 15 Boot Assist Module (BAM)

15.1	Introduction	15-1
15.1.1	Overview	15-1
15.1.2	Features	15-2
15.1.3	Modes of Operation	15-2
15.2	Memory Map	15-3
15.3	Functional Description	15-3
15.3.1	BAM Program Resources	15-3
15.3.2	BAM Program Operation	15-4
15.3.3	Interrupts	15-16
15.4	Revision History	15-17

Chapter 16 Enhanced Modular Input/Output Subsystem (eMIOS)

16.1	Introduction	16-1
16.1.1	Overview	16-3
16.1.2	Features	16-3
16.1.3	eMIOS Operating Modes	16-4
16.2	External Signal Description	16-5
16.2.1	External Signals	16-5
16.3	Memory Map/Register Definition	16-6

16.3.1	Register Description	16-8
16.4	Functional Description	16-22
16.4.1	Bus Interface Unit (BIU)	16-23
16.4.2	STAC Client Submodule	16-23
16.4.3	Global Clock Prescaler Submodule (GCP)	16-24
16.4.4	Unified Channel (UC)	16-25
16.5	Initialization/Application Information	16-75
16.5.1	Considerations on Changing a UC Mode	16-75
16.5.2	Generating Correlated Output Signals	16-75
16.5.3	Time Base Generation	16-75
16.6	Document Revision History	16-78

Chapter 17

Enhanced Time Processing Unit (eTPU)

17.1	Introduction	17-1
17.1.1	MPC5565 eTPU Implementation	17-1
17.1.2	Block Diagram	17-2
17.1.3	eTPU Operation Overview	17-3
17.1.4	eTPU Engine	17-4
17.1.5	Features	17-8
17.2	Modes of Operation	17-10
17.2.1	User Configuration Mode	17-10
17.2.2	User Mode	17-10
17.2.3	Debug Mode	17-11
17.2.4	Module Disable Mode	17-11
17.2.5	eTPU Mode Selection	17-11
17.3	External Signal Description	17-11
17.3.1	Overview	17-11
17.3.2	Output and Input Channel Signals	17-12
17.4	Memory Map and Register Definition	17-14
17.4.1	eTPU Memory Map Overview	17-14
17.4.2	eTPU Register Addresses	17-16
17.4.3	System Configuration Registers	17-18
17.4.4	Time Base Registers	17-25
17.4.5	Global Channel Registers	17-32
17.4.6	Channel Configuration and Control Registers	17-39
17.5	Functional Description	17-44
17.6	Initialization/Application Information	17-44
17.7	Document Revision History	17-45

Chapter 18

Enhanced Queued Analog-to-Digital Converter (eQADC)

18.1	Introduction	18-1
18.1.1	Block Diagram	18-2
18.1.2	Overview	18-2
18.1.3	Features	18-4
18.1.4	Modes of Operation	18-5
18.2	External Signal Description	18-7
18.3	Memory Map and Register Definition	18-10
18.3.1	eQADC Memory Map	18-10
18.3.2	eQADC Register Descriptions	18-13
18.3.3	On-Chip ADC Registers	18-37
18.4	Functional Description	18-44
18.4.1	Data Flow in the eQADC	18-44
18.4.2	Command/Result Queues	18-60
18.4.3	eQADC Command FIFOs	18-60
18.4.4	Result FIFOs	18-83
18.4.5	On-Chip ADC Configuration and Control	18-87
18.4.6	Internal/External Multiplexing	18-95
18.4.7	eQADC eDMA/Interrupt Request	18-99
18.4.8	eQADC Synchronous Serial Interface (SSI) Submodule	18-102
18.4.9	Analog Submodule	18-107
18.5	Initialization/Application Information	18-109
18.5.1	Multiple Queues Control Setup Example	18-109
18.5.2	eQADC/eDMA Controller Interface	18-113
18.5.3	Sending Immediate Command Setup Example	18-115
18.5.4	Modifying Queues	18-115
18.5.5	Command Queue and Result Queue Usage	18-116
18.5.6	ADC Result Calibration	18-117
18.5.7	eQADC versus QADC	18-120
18.6	Document Revision History	18-123

Chapter 19

Deserial Serial Peripheral Interface (DSPI)

19.1	Introduction	19-1
19.1.1	Block Diagram	19-2
19.1.2	Overview	19-2
19.1.3	Features	19-3
19.1.4	Modes of Operation	19-5
19.2	External Signal Description	19-6
19.2.1	Signal Overview	19-6
19.2.2	Signal Names and Descriptions	19-6
19.3	Memory Map and Register Definition	19-8
19.3.1	Memory Map	19-8

19.3.2	Register Descriptions	19-9
19.4	Functional Description	19-32
19.4.1	Modes of Operation	19-34
19.4.2	Start and Stop of DSPI Transfers	19-35
19.4.3	Serial Peripheral Interface (SPI) Configuration	19-36
19.4.4	Deserial Serial Interface (DSI) Configuration	19-39
19.4.5	Combined Serial Interface (CSI) Configuration	19-50
19.4.6	DSPI Baud Rate and Clock Delay Generation	19-52
19.4.7	Transfer Formats	19-55
19.4.8	Continuous Serial Communications Clock	19-62
19.4.9	Interrupts/DMA Requests	19-64
19.4.10	Power Saving Features	19-65
19.5	Initialization and Application Information	19-66
19.5.1	How to Change Queues	19-66
19.5.2	Baud Rate Settings	19-67
19.5.3	Delay Settings	19-68
19.5.4	MPC5xx QSPI Compatibility with the DSPI	19-68
19.5.5	Calculation of FIFO Pointer Addresses	19-69
19.6	Document Revision History	19-71

Chapter 20

Enhanced Serial Communication Interface (eSCI)

20.1	Introduction	20-1
20.1.1	Block Diagram	20-1
20.1.2	Overview	20-2
20.1.3	Features	20-2
20.1.4	Modes of Operation	20-2
20.2	External Signal Description	20-3
20.2.1	Detailed Signal Description	20-3
20.3	Memory Map and Register Definition	20-3
20.3.1	Overview	20-3
20.3.2	Module Memory Map	20-3
20.3.3	Register Descriptions	20-4
20.4	Functional Description	20-18
20.4.1	Overview	20-18
20.4.2	Data Format	20-19
20.4.3	Baud Rate Generation	20-20
20.4.4	Transmitter	20-21
20.4.5	Receiver	20-26
20.4.6	Single-Wire Operation	20-33
20.4.7	Loop Operation	20-33
20.4.8	Modes of Operation	20-34
20.4.9	Interrupt Operation	20-34
20.4.10	Using the LIN Hardware	20-37
20.5	Document Revision History	20-41

Chapter 21

FlexCAN2 Controller Area Network

Chapter 1

Introduction

1.1 Overview

The MPC5565 microcontroller (MCU) is a member of the MPC5500 family of next generation powertrain microcontrollers built on Power Architecture™ technology. The MPC5500 family contains a host processor core that complies with the Power Architecture embedded category, which is 100 percent user mode compatible with the original Power PC™ user instruction set architecture (UISA). This family of parts contains many new features coupled with high-performance CMOS technology to provide significant performance improvement over the MPC565.

The e200z6 CPU of the MPC5500 family is part of the family of CPU cores that implement versions built on the Power Architecture embedded category. This core also has additional instructions, including digital signal processing (DSP) instructions, beyond the classic PowerPC instruction set.

The MPC5565 has two levels of memory hierarchy. The fastest accesses are to the 8 KB unified cache. The next level in the hierarchy contains up to 80 KB of internal SRAM and 2 MB flash memory. Both the internal SRAM and the flash memory can hold instructions and data. The external bus interface is designed to support most of the standard memories used with the MPC5xx family.

The complex I/O timer functions of the MPC5500 family are performed by an enhanced time processor unit engine (eTPU). The eTPU engine controls 32 hardware channels. The eTPU has been enhanced over the TPU by providing 24-bit timers, double-action hardware channels, a variable number of parameters per channel, angle clock hardware, and additional control and arithmetic instructions. The eTPU can be programmed using a high-level programming language. The less complex timer functions of the MPC5500 family are performed by the enhanced modular input/output system (eMIOS). The eMIOS' 24 hardware channels are capable of single action, double action, pulse-width modulation (PWM), and modulus counter operation. Motor control capabilities include edge-aligned and center-aligned PWM.

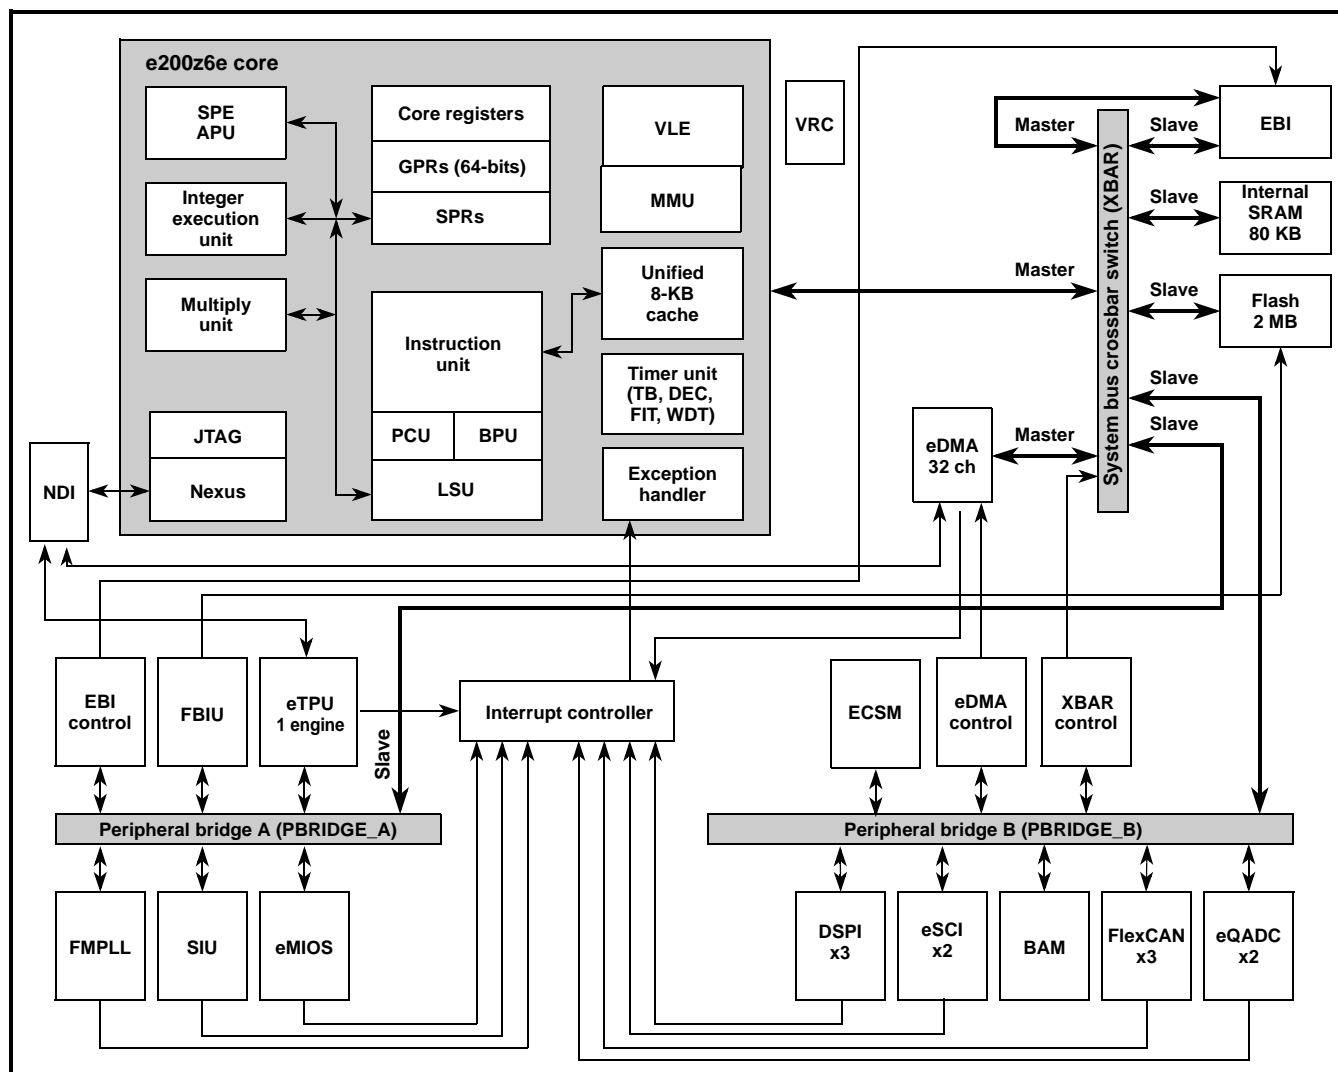

Off-chip communication is performed by a suite of serial protocols including: three controller area networks (FlexCANs); three enhanced deserial/serial peripheral interface (DSPIs); and two enhanced serial communications interfaces (eSCIs).

The DSPIs support pin reduction through hardware serialization and deserialization of timer channels and general-purpose input/output (GPIO) signals.

The MCU has two on-chip 40-channel enhanced queued dual analog to digital converters (eQADC).

The system integration unit (SIU) performs several chip-wide configuration functions. Pad configuration and general-purpose input and output (GPIO) are controlled from the SIU. External interrupts and reset control are also found in the SIU. The internal multiplexer submodule (SIU_DISR) provides multiplexing of eQADC trigger sources, daisy chaining the DSPIs, and external interrupt signal multiplexing.

Figure 1-1 is a block diagram of the MPC5565.

Legend

MPC5565 device modules

- BAM** – Boot assist module
- CAN** – Controller area network (FlexCAN)
- DSPI** – Deserial/serial peripheral interface
- EBI** – External bus interface
- ECISM** – Error correction status module
- eDMA** – Enhanced direct memory access
- eMIOS** – Enhanced modular I/O system
- eQADC** – Enhanced queued analog/digital converter
- eSCI** – Enhanced serial communications interface
- eTPU** – Enhanced time processing unit
- FBIU** – Flash bus interface unit
- FMPLL** – Frequency modulated phase-locked loop
- INTC** – Interrupt controller
- NDI** – Nexus developmental interface
- SIU** – System integration unit
- SRAM** – Internal static RAM
- VRC** – Voltage regulator controller
- XBAR** – System bus crossbar switch

e200z6e core components

- APU** – Auxiliary processing unit
- BIU** – Bus interface unit
- BPU** – Branch processing unit
- DEC** – Decrementer
- FIT** – Fixed interval timer
- GPR** – General-purpose register
- JTAG** – JTAG controller
- LSU** – Load/store unit
- MMU** – Memory management unit
- PCU** – Program counter unit
- SPE** – Signal processing engine
- SPR** – Special purpose register
- TB** – Time base
- VLE** – Variable length encoding
- WDT** – Watchdog timer
- ↔** – System bus

Figure 1-1. MPC5565 Block Diagram

1.2 Features

This section provides a high-level description of the features found in the MPC5565.

- Operating parameters
 - Fully static operation, up to 132 MHz
 - -40 to 150 °C junction temperature
 - Low-power design
 - Less than 1.2 Watts power dissipation
 - Designed for dynamic power management of core and peripherals
 - Software-controlled clock gating of peripherals
 - Separate power supply for stand-by operation for portion of internal SRAM
 - Fabricated in 0.13 μm process
 - 1.5 V internal logic
 - Input and output pins with 3.0–5.25 V range
 - 35% or 65% V_{DDEH} CMOS switch levels (with hysteresis)
 - Selectable hysteresis
 - Selectable slew rate control
 - External bus support 1.62–3.6 V operation and Nexus pins support 2.5–3.6 V operation
 - Selectable drive strength control
 - Unused pins configurable as GPIO
 - Designed with EMI reduction techniques
 - Frequency modulated phase-locked loop
 - On-chip bypass capacitance
 - Selectable slew rate and drive strength
- High-performance e200z6 core processor
 - 32-bit CPU built on Power Architecture™ technology
 - Freescale Variable Length Encoding (VLE) enhancements for code size footprint reduction
 - Thirty-two 64-bit general-purpose registers (GPRs)
 - Memory management unit (MMU) with 32-entry fully-associative translation look-aside buffer (TLB)
 - Branch processing unit
 - Fully pipelined load/store unit
 - Eight KB unified cache with line locking
 - Two-way set associative
 - Two 32-bit fetches per clock
 - Eight-entry store buffer
 - Way locking
 - Supports assigning cache as instruction or data only on a per-way basis

- Supports tag and data parity
- Vectored interrupt support
- Interrupt latency is less than 70 ns @132 MHz (measured from interrupt request to execution of first instruction of interrupt exception handler)
- Reservation instructions for implementing read-modify-write constructs (internal SRAM and flash)
- Signal processing engine (SPE) auxiliary processing unit (APU) operating on 64-bit GPRs
- Floating point
 - IEEE[®] 754 compatible with software wrapper
 - Single precision in hardware, double precision with software library
 - Conversion instructions between single precision floating point and fixed point
- Long cycle time instructions, except for guarded loads, do not increase interrupt latency in the MPC5565; to reduce latency, long cycle time instructions are aborted upon interrupt requests
- Extensive system development support through Nexus debug module
- System bus crossbar switch (XBAR)
 - Three master ports, five slave ports.
 - 32-bit address bus, 64-bit data bus
 - Simultaneous accesses from different masters to different slaves (there is no clock penalty when a parked master accesses a slave)
- Enhanced direct memory access (eDMA) controller
 - 32 channels support independent 8-, 16-, 32-bit single value or block transfers
 - Supports variable sized queues and circular queues
 - Source and destination address registers are independently configured to post-increment or remain constant
 - Each transfer is initiated by a peripheral, CPU, or eDMA channel request
 - Each eDMA channel can optionally send an interrupt request to the CPU on completion of a single value or block transfer
- Interrupt controller (INTC)
 - 231 interrupt request registers¹
 - 208 peripheral interrupt requests
 - Eight software settable sources
 - 16 reserved
 - Unique 9-bit vector per interrupt source
 - 16 priority levels with fixed hardware arbitration within priority levels for each interrupt source
 - Priority elevation for shared resources

1. Although this device has a maximum of 231 interrupts, the logic requires that the total number of interrupts be divisible by four. Therefore, the total number of interrupts specified for this device is 232.

- Frequency modulated phase-locked loop (FMPLL)
 - Input clock frequency: 8–20 MHz
 - Current controlled oscillator (ICO) range from 48 MHz to maximum device frequency
 - Reduced frequency divider (RFD) for reduced frequency operation without re-lock
 - Four selectable modes of operation
 - Programmable frequency modulation
 - Lock detect circuitry continuously monitors lock status
 - Loss-of-clock (LOC) detection for reference and feedback clocks
 - Self-clocked mode (SCM) operation
 - On-chip loop filter (reduces number of external components required)
 - Engineering clock output configurable to divide-by-2 to 126 of the system clock frequency
- External bus interface (EBI)
 - 1.8–3.3 V nominal I/O voltage
 - 324 BGA: 16-bit data bus, 20-bit address bus is default, but configurable to 24-bit address bus. Although this device is designed to support a 32-bit EBI data bus, only 16 data bus pins are available and connected on the 324 BGA package. The 496-pin VertiCal assembly provides the calibration functionality.
 - Memory controller with support for various memory types
 - Non-burst SDR flash and SRAM
 - Asynchronous/legacy flash and SRAM
 - Most standard memories used with the MPC5xx family
 - Configurable bus speed modes
 - 50% of system frequency
 - 25% of system frequency
 - Support for external master accesses to internal addresses
 - Burst support
 - Bus monitor
 - User selectable
 - Programmable timeout period (with eight external bus clock resolution)
 - Four chip selects: $\overline{CS}[0:3]$ multiplexed with $ADDR[8:11]$.
 - Two write/byte enable ($\overline{WE}/\overline{BE}[0:1]$) signals in the 324-pin package and the 496 pin assembly.
 - Configurable wait states (via chip selects)
 - Optional automatic CLKOUT gating to save power and reduce EMI
 - Compatible with MPC5xx external bus (with some limitations):
Selectable drive strengths; 10 pF, 20 pF, 30 pF, 50 pF
- Calibration bus interface
 - Calibration bus interface only accessible through 496-pin VertiCal assembly top connector
 - 1.8–3.3 V nominal I/O voltage

- Memory controller shared with EBI
- 16-bit data bus
- 21-bit address bus with no support for the least significant address bit (ADDR31)
- Up to 22 bit address space providing a 4 MB addressing range (the two most significant bits shared with CAL_CS[2:3])
- Chip selects: up to three chip selects (CAL_CS[0] and CAL_CS[2:3] shared with CAL_ADDR[10:11])
- System integration unit (SIU)
 - Centralized GPIO control of bus pins: 324 BGA package with 150 pins
 - Centralized pad control on a per-pin basis
 - System reset monitoring and generation
 - External interrupt inputs, filtering and control
- Error correction status module (ECSM)
Configurable error-correcting codes (ECC) reporting for internal SRAM and flash memories
- On-chip flash
 - Two MB burst flash memory
 - 256 KB × 64-bit configuration
 - Censorship protection scheme to prevent flash content visibility
 - Hardware read-while-write feature that can erase/program blocks while other blocks are read (used for EEPROM emulation and data calibration)
 - 20 blocks with sizes ranging from 16–128 KB to support features such as boot block, operating system block, and EEPROM emulation. Blocks are structured as follows:
 - 2 x 16 KB
 - 2 x 48 KB
 - 2 x 64 KB
 - 14 x 128 KB
 - Read while write with multiple partitions
 - Page programming mode to support rapid end of line programming
 - Hardware programming state machine
- Configurable cache memory, 0–8 KB
 - Two-way set-associative unified (instruction and data) cache
 - Decouples processor performance from system memory performance
- On-chip internal static RAM (SRAM)
 - 80 KB general-purpose SRAM of which 32 KB are on standby power
 - ECC performs single-bit correction, double-bit error detection
- Boot assist module (BAM)
 - Enables and manages the transition of MCU from reset to user code execution in the following configurations:

- User application can boot from internal or external flash memory
 - Download and execution of code via FlexCAN or eSCI
 - User application can boot with either classic Power Architecture code or VLE code
- Enhanced modular I/O system (eMIOS)
 - 24 orthogonal channels with double action, PWM, and modulus counter functionality
 - Supports all DASM and PWM modes of MIOS14 (MPC5xx)
 - Four selectable time bases plus a shared time or angle counter bus
 - DMA and interrupt request support
 - Motor control capability
- Enhanced time processor unit (eTPU)
 - One engine 32-channel engine
 - 24-bit timer resolution
 - 12 KB shared code memory, 2.5 KB shared data memory
 - Event-triggered timer subsystem
 - High-level assembler/compiler
 - Variable number of parameters to allocate per channel
 - Double match/capture channels
 - Angle clock hardware support
 - Shared time or angle counter bus for all eTPU and eMIOS modules
 - DMA and interrupt request support
 - Nexus class 3 debug support (with some class 4 support)
- Enhanced queued analog/digital converter (eQADC)
 - Two independent ADCs with 12-bit A/D resolution
 - Common mode conversion range of 0–5 V
 - 40 single-ended input channels, expandable to 65 channels with external multiplexers on the 324 BGA package
 - Eight channels can be used as four pairs of differential analog input channels
 - 10-bit accuracy at 400 ksamples/sec., 8-bit accuracy at 800 ksamples/sec.
 - Supports six FIFO queues with fixed priority
 - Queue modes with priority-based preemption; initiated by software command, internal (eTPU and eMIOS), or external triggers
 - DMA and interrupt request support
 - Supports all functional modes from QADC (MPC5xx family)
- Three deserial serial peripheral interface modules (DSPI)
 - Serial peripheral interface (SPI)
 - Full duplex communication ports with interrupt and eDMA request support
 - Supports all functional modes from QSPI submodule of QSMCM (MPC5xx family)
 - Support for queues in RAM

- Six chip selects, expandable to 64 with external demultiplexers
 - Programmable frame size, baud rate, clock delay, and clock phase on a per-frame basis
 - Modified SPI mode for interfacing to peripherals with longer setup time requirements
- Deserial serial interface (DSI)
 - Pin reduction by hardware serialization and deserialization of eTPU and eMIOS channels
 - Chaining of DSI submodules
 - Triggered transfer control and change in data transfer control (for reduced EMI)
- Two enhanced serial communication interface (eSCI) modules
 - UART mode provides NRZ format and half or full duplex interface
 - eSCI bit rate up to 1 Mb/s
 - Advanced error detection, and optional parity generation and detection
 - Word length programmable as 8 or 9 bits
 - Separately enabled transmitter and receiver
 - LIN support
 - DMA support
 - Interrupt request support
- Three FlexCANs
 - 64 message buffers each
 - Full implementation of the CAN protocol specification, Version 2.0B
 - Based on and including all existing features of the Freescale TouCAN module
 - Programmable acceptance filters
 - Individual receive filtering per message buffer
 - Short latency time for high-priority transmit messages
 - Arbitration scheme according to message ID or message buffer number
 - Listen-only mode capabilities
 - Programmable clock source: system clock or oscillator clock
 - Reception queue possible by setting more than one receive message buffer with the same ID
 - Backwards compatibility with previous FlexCAN modules
- Nexus development interface (NDI)
 - Per IEEE®-ISTO 5001-2003
 - Real-time development support for Power Architecture core and eTPU engine through Nexus class 3 (some class 4 support)
 - Data trace of eDMA accesses
 - Read and write access
 - Configured via the IEEE® 1149.1 (JTAG) port
 - High-bandwidth mode for fast message transmission
 - Reduced bandwidth mode for reduced pin usage

- IEEE® 1149.1 JTAG controller (JTAGC)
 - IEEE® 1149.1-2001 test access port (TAP) interface
 - JCOMP input that provides the ability to share the TAP; selectable modes of operation include JTAGC/debug or normal system operation
 - 5-bit instruction register that supports IEEE® 1149.1-2001 defined instructions
 - 5-bit instruction register that supports additional public instructions
 - Three test data registers: a bypass register, a boundary scan register, and a device identification register
 - TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry
- Voltage regulator controller (VRC)

Provides a low-cost solution to power the core logic; it reduces the number of power supplies required from the customer power supply chip
- POR block

Provides initial reset condition up to the voltage at which pins ($\overline{\text{RESET}}$) can be read safely; it does not guarantee the safe operation of the chip at specified minimum operating voltages

1.3 MPC5500 Family Comparison

The following table compares the product features of the MPC5554 and the MPC5565:

Table 1-1. MPC5500 Product Family Comparison

MPC5500 Device Feature		MPC5554	MPC5565
Power PC core		e200z6	e200z6
Variable length instruction support		Y	Y
Unified cache (KB)		32 ¹	8 ²
Memory management unit (MMU) entries		32	32
Crossbar connections		3 x 5	3 x 5
Core Nexus		Class 3 + (NZ6C3)	Class 3 + (NZ6C3)
SRAM (KB)		64	80
Flash	Main array (MB)	2 ³	2
	Shadow block (KB)	1	1
External bus interface (EBI) bit-width	Data	32	32 ⁴
	Address	24 ⁵	24 ⁵
Calibration bus interface (CBI)		–	Y
Direct memory access (DMA) channels		32	32
DMA Nexus		Class 3	Class 3
Serial		2	2
	eSCI A	Y	Y
	eSCI B	Y	Y

Table 1-1. MPC5500 Product Family Comparison (continued)

MPC5500 Device Feature	MPC5554	MPC5565
Controller area network (FlexCAN)	3	3 ⁶
CAN A buffers	64	64
CAN B buffers	64	64
CAN C buffers	64	64
CAN D buffers	—	—
CAN E buffers	—	—
Deserial/serial peripheral interface (SPI)	4	3
DSPI A	Y	—
DSPI B	Y	Y
DSPI C	Y	Y
DSPI D	Y	Y
eMIOS channels	24	24
eTPU channels	64	32
eTPU A	Y	Y
eTPU B	Y	—
Code memory (KB)	16	12
Parameter RAM (KB)	3	2.5
Nexus	Class 3	Class 3
Interrupt controller channels	300	231
Analog to digital converter channels	40	40
ADC A	Y	Y
ADC B	Y	Y
Fast Ethernet controller (FEC)	—	—
FlexRay	—	—
FlexRay Nexus data trace	—	—
Frequency modulated phase lock loop (FMPLL)	Y	Y
Voltage regulator controller (VRC)	Y	Y

¹ 8-way associative

² 2-way associative

³ 32-byte flash page size for programming

⁴ EBI limited to a 16-bit data bus on the 324 package

⁵ Select either ADDR[8:31] or ADDR[6:29] to configure a 24-bit address bus

⁶ Updated FlexCAN module with optional individual receive filters

1.4 Detailed Features

The following sections provide detailed information about each of the on-chip modules.

1.4.1 e200z6 Core Overview

The device uses the e200z6 core explained in detail in the *e200z6 PowerPC™ Core Reference Manual*. The e200z6 CPU uses a seven-stage pipeline for instruction execution:

- Instruction fetch 1
- Instruction fetch 2
- Instruction decode and register file read
- Execute 1
- Execute 2 and memory access 1
- Execute 3 and memory access 2
- Register writeback

The operation of the pipeline stages overlap so that most instructions execute in a single-clock.

The integer execution unit consists of a 32-bit arithmetic unit (AU), a logic unit (LU), a 32-bit barrel shifter, a mask-insertion unit (MIU), a condition register manipulation unit (CRU), a count-leading-zeros unit (CLZ), a 32 x 32 hardware multiplier array, result feed-forward hardware, and support hardware for division.

Most arithmetic and logical operations are executed in a single cycle with the exception of multiply and divide instructions, which are implemented with a pipelined hardware array. The CLZ unit operates in a single clock cycle.

The instruction unit contains an incremental program counter (PC) and a dedicated branch address adder to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer capable of holding six sequential instructions and two branch target instructions.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in execution time of three clocks. Conditional branches which are not taken execute in a single clock. Branches with successful look-ahead and target prefetching have an effective execution time of one clock.

Memory load and store operations are provided for byte, halfword, word (32-bits), and doubleword (64-bits) data with automatic zero or sign extension of byte and halfword load data. These instructions can be pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The condition register unit supports the condition register (CR) and condition register operations defined by the Power Architecture technology. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Vectored and auto-vectored interrupts are supported by the CPU. Vectored interrupt supports unique interrupt handlers invoked with no software overhead for multiple interrupt sources.

The signal processing extension (SPE) APU supports vector instructions (SIMD) operating on 16- and 32-bit fixed-point data types, as well as 32-bit IEEE®-754 single-precision floating-point formats, and supports single-precision floating-point operations in a pipelined fashion. The 64-bit general-purpose register file is used for source and destination operands, and there is a unified storage model for single-precision floating-point data types of 32-bits and the normal integer type. Low latency fixed-point and floating-point add, subtract, multiply, divide, compare, and conversion operations are provided, and most operations can be pipelined.

The CPU includes support for Variable Length Encoding (VLE) instruction enhancements that have modified instruction set that uses a combination of 16- and 32-bit instructions from the classic Power Architecture instruction. This reduces the code size without noticeably affecting performance. The classic Power Architecture instruction set and VLE instruction set are available concurrently. Regions of the memory map are designated as PPC or VLE using an additional configuration bit in each table look-aside buffer (TLB) entry in the MMU.

1.4.2 System Bus Crossbar Switch (XBAR)

The system bus' multi-port crossbar (XBAR) switch supports simultaneous connections between three master ports and five slave ports. The crossbar supports a 32-bit address bus width and a 64-bit data bus width on all master and slave ports.

The crossbar allows concurrent transactions from any master port to any slave port. It is possible to use all master ports and slave ports at the same time as a result of independent master requests. If a slave port is simultaneously requested by more than one master port, arbitration logic selects the highest priority master and grants it ownership of the slave port. All other masters requesting that slave port must wait until the higher priority master completes its transactions. By default, masters requests' have equal priority and are granted access to a slave port in round-robin fashion based on the last master ID granted access.

1.4.3 Enhanced Direct Memory Access (eDMA)

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data movements via 32 programmable channels, with minimal intervention from the CPU. The hardware microarchitecture includes a DMA engine which performs source and destination address calculations, and the actual data movement operations, along with an SRAM-based memory containing the transfer control descriptors (TCD) for the channels. This implementation is used to minimize the overall module size.

1.4.4 Interrupt Controller (INTC)

The interrupt controller (INTC) provides priority-based preemptive scheduling of interrupt requests, suitable for statically scheduled real-time systems. The INTC allows interrupt request servicing from 231 total interrupt vectors.

For high-priority interrupt requests, the time from when the peripheral interrupt request asserts to when the processor executes the interrupt service routine (ISR) is minimized. A unique vector for each interrupt request source is used to quickly determine which ISR to execute. The INTC module provides a number of priorities to ensure that lower priority ISRs do not delay the execution of higher priority ISRs. Software is used to configure the interrupt priorities for each interrupt source.

When multiple tasks share a resource, coherent accesses to that resource must be supported. The INTC supports the priority ceiling protocol for coherent accesses. By providing a modifiable priority mask, the priority level can be raised temporarily so that no task can preempt another task that shares the same resource.

Multiple processors can assert interrupt requests to each other through software settable interrupt requests (by using application software to assert requests). These maskable interrupt requests can divide the software into a high-priority portion and a low-priority portion for servicing the interrupt requests. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR asserts a software settable interrupt request to finish the servicing in a lower priority ISR.

1.4.5 Frequency Modulated Phase-Locking Loop (FMPLL)

The frequency modulated phase-locking loop (FMPLL) generates high-speed system clocks from an 8–20 MHz crystal oscillator or an external clock generator. Furthermore, the FMPLL supports programmable frequency modulation of the system clock. The PLL multiplication factor, output clock divider ratio, modulation depth, and modulation rate are all software configurable.

1.4.6 External Bus Interface (EBI)

The external bus interface (EBI) controls data transfer across the crossbar switch to/from memories or peripherals in the external address space. The EBI is available on the 324 BGA package only. The EBI also enables an external master to access internal address space. The EBI includes a memory controller that generates interface signals to support a variety of external memories. The memory controller supports single data rate (SDR) burst mode flash, external SRAM, and asynchronous memories. In addition, the EBI supports up to four regions (via chip selects), along with programmed region-specific attributes.

1.4.7 Calibration Bus Interface (CBI)

The calibration bus controls data transfer across the crossbar switch to/from memories or peripherals connected to the *VertiCal* connector. The calibration bus is only available when the silicon is packaged in the *VertiCal* calibration assembly. The bus shares the memory controller and most of the control logic with the EBI but the two buses use separate pads. The calibration bus memory controller supports single data rate (SDR) non-burst mode flash, SRAM, and asynchronous memories. In addition, the bus supports up to

three regions via dedicated calibration chip selects (two chip selects multiplexed with two address bits), along with programmed region-specific attributes.

1.4.8 System Integration Unit (SIU)

The device's system integration unit (SIU) controls MCU reset configuration, pad configuration, external interrupt, general-purpose I/O (GPIO), internal peripheral multiplexing, and the system reset operation. The reset configuration module contains the external pin boot configuration logic. The pad configuration module controls the static electrical characteristics of I/O pins. The GPIO module provides uniform and discrete input/output control of the I/O pins of the MCU. The reset controller performs reset monitoring of internal and external reset sources, and drives the RSTOUT pin. The SIU is accessed by the e200z6 core through the crossbar switch.

1.4.9 Error Correction Status Module (ECSM)

The error correction status module (ECSM) provides status information regarding platform memory errors reported by error-correcting codes.

1.4.10 Flash Memory

The MPC5565 provides 2 MB of programmable, non-volatile, flash memory storage. Non-volatile memory (NVM) can be used for instruction and/or data storage.

The flash memory has a flash bus interface unit (FBIU) that connects the system bus to a dedicated flash memory array controller. The FBIU supports a 64-bit data bus width at the system bus port, and a 256-bit read data interface to flash memory. The FBIU contains two 256-bit prefetch buffers, and a prefetch controller that prefetches sequential lines of data from the flash array into the buffer. Prefetch buffer hits allow no-wait responses. Normal flash array accesses are registered in the FBIU and are forwarded to the system bus on the following cycle, incurring three wait-states. Prefetch operations can be automatically controlled, as well as restricted to servicing a single bus master. Prefetches can also require a trigger for instruction or data accesses.

1.4.11 Cache

The e200z6 core supports an eight-KB, two-way set-associative, unified (instruction and data) cache with a 32-byte line size. The cache improves system performance by providing low-latency data to the e200z6 instruction and data pipelines, which decouples processor performance from system memory performance. The cache is virtually indexed and physically tagged. The e200z6 does not provide hardware support for cache coherency in a multi-master environment. Software must be designed to maintain cache coherency with other possible bus masters.

Both instruction and data accesses are performed using a single bus connected to the cache. The processor uses virtual addresses to index the cache array. The memory management unit (MMU) provides the virtual-to-physical address conversion to perform the cache tag compare. The MMU can pass the virtual addresses to the cache as the physical address without the conversion. If the physical address matches a valid cache tag entry, the access hits in the cache. For a read operation, the cache supplies the data to the

processor, and for a write operation, the data from the processor is written to cache. If the access does not match a valid cache tag entry (misses in the cache), or a write access is required to memory, the cache performs a bus cycle on the system bus.

1.4.12 Static RAM (SRAM)

The MPC5500 family internal SRAM module provides a general-purpose memory block that supports mapped read/write accesses from any master. The SRAM size is 80 KB. Included within the SRAM block is a 32-KB block powered by a separate supply for standby operation and ECC error correction and detection.

1.4.13 Boot Assist Module (BAM)

The boot assist module (BAM) is read-only memory programmed by Freescale and is identical for all MCUs with an e200z6 core. The BAM program executes every time the MCU is powered on, or when reset in normal mode. The BAM supports these boot modes:

- Booting from internal flash memory
- Single master booting from external memory
- Serial boot loading (program is downloaded to SRAM over an eSCI or FlexCAN peripheral and then executed)

The BAM reads the reset configuration halfword (RCHW) from flash memory (either internal or external) to configure the device hardware. The MMU is then configured for all resources and maps all physical addresses to logical addresses with the minimum address translation, to allow application boot code to execute as either Classic Power Architecture Book E code (default) or as Freescale VLE code.

1.4.14 Enhanced Management Input/Output System (eMIOS)

The enhanced modular I/O system (eMIOS) module generates or measures time events. A unified channel (UC) module provides a consistent interface to a superset of all the MIOS channel functionality. This allows more flexibility to program each unified channel for different functions in different applications. To identify up to two timed events, each UC uses two comparators, a time base selector, and registers. This structure can produce match events to measure or generate a waveform. Alternatively, input events can capture the time base, allowing measurement of an input signal.

1.4.15 Enhanced Time Processing Unit (eTPU)

The enhanced time processing unit (eTPU) is an enhanced coprocessor designed for timing control. Operating in parallel with the host CPU, the eTPU processes instructions and real-time input events, performs output waveform generation, and accesses shared data without host intervention. Consequently, for each timer event, the CPU setup and service times are minimized or eliminated. In the MCU, the TPU engine is combined with shared instruction and data RAM to form a powerful time processing subsystem.

The MPC5565 has one eTPU engine. High-level assembler/compiler and documentation can be used to develop customized functions for the eTPU. The eTPU supports several features of older TPU versions, making it easy to port older applications.

1.4.16 Enhanced Queued A/D Converter (eQADC)

The enhanced queued analog to digital converter (eQADC) module provides accurate and fast conversions for a wide range of applications. The eQADC provides a parallel interface to two on-chip analog to digital converters (ADCs), and a single master-to-single slave serial interface to an off-chip external device. The two on-chip ADCs are designed to access all the analog channels.

The eQADC transfers commands from multiple command FIFOs (CFIFOs) to the on-chip ADCs or to the external device. The module can also receive data from the on-chip ADCs or from an off-chip external device into multiple result FIFOs (RFIFOs) in parallel, independently of the CFIFOs. The eQADC supports software and external hardware triggers from other modules to initiate transfers of commands from the CFIFOs to the on-chip ADCs or to the external device. It also monitors the fullness of CFIFOs and RFIFOs, and accordingly generates eDMA or interrupt requests to control data movement between the FIFOs and the system memory, which is external to the eQADC.

1.4.17 Deserial/Serial Peripheral Interface (DSPI)

The deserial serial peripheral interface (DSPI) module provides a synchronous serial interface for communication between the MCU and external devices. The DSPI supports pin-count reduction through serialization and deserialization of eTPU channels, eMIOS channels and memory-mapped registers. The channels and register content are transmitted using a SPI-like protocol.

The MPC5565 has three DSPI modules (B, C, and D). The DSPIs have three configurations:

- Serial peripheral interface (SPI) configuration where the DSPIs operate as serial ports only with support for queues.
- Deserial serial interface (DSI) configuration where the DSPIs serialize eTPU and eMIOS output channels, and deserialize the input data by passing it to the eTPU and eMIOS input channels.
- Combined serial interface (CSI) configuration where the DSPIs operate in both SPI and DSI configurations, interleaving DSI frames with SPI frames, and giving priority to SPI frames.

For queued operations, the SPI queues reside in system memory external to the DSPI. Data transfers between the memory and the DSPI FIFOs use the eDMA controller or the host software.

1.4.18 Enhanced Serial Communications Interface (eSCI)

The enhanced serial communications interface (eSCI) allows asynchronous serial communications with peripheral devices and other MCUs. It includes special support to interface to local interconnect network (LIN) slave devices. The MPC5565 has two eSCI modules (A and B).

1.4.19 Flexible Controller Area Network (FlexCAN)

The MCU contains three controller area network (FlexCAN) modules. Each FlexCAN module is a communication controller implementing the CAN protocol according to CAN Specification version 2.0B. The CAN protocol is designed to be used primarily as a vehicle serial data bus, meeting the specific requirements of this field: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness, and required bandwidth. Each FlexCAN module contains 64 message buffers.

1.4.20 Nexus Development Interface (NDI)

The Nexus development interface (NDI) module provides real-time development support capabilities for the MPC5500 family's MCU built on the Power Architecture in compliance with the IEEE®-ISTO 5001-2003 standard. This development support is supplied for MCUs without requiring external address and data pins for internal visibility. The NDI module integrates several Nexus modules to provide the development support interface for the MPC5500 family. The NDI module interfaces to the host processor, single or dual eTPU processors, and internal buses to provide development support as per the IEEE®-ISTO 5001-2003 standard. The development support provided includes program trace, data trace, watchpoint trace, ownership trace, run-time access to the MCU internal memory map, Nexus trace of eDMA transfers, and access to the Power Architecture and eTPU internal registers during halt, via the auxiliary port. The Nexus interface also supports a JTAG only mode using only the JTAG pins.

1.4.21 JTAG Controller (JTAGC)

The JTAG controller (JTAGC) module provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE® 1149.1-2001 standard. All data input to and output from the JTAGC module is communicated in serial format. The JTAGC module is compliant with the IEEE® 1149.1-2001 standard.

1.5 MPC5500 Family Memory Map

This section describes the MPC5500 family memory map. All addresses in the device, including those that are reserved, are identified in the tables. The addresses represent the physical addresses assigned to each module. Logical addresses are translated by the MMU into physical addresses.

Reserved register bits are allocated for future products and have a default value of zero. When writing to a register, the reserved bits default values must be written as well. Most device features are activated by writing a non-zero value to them.

Reserved memory is allocated for future products, therefore do not write to memory segments that are designated as reserved.

Under software control of the MMU, the logical addresses allocated to modules can be changed on a minimum of a 4 KB boundary. Peripheral modules may be redundantly mapped. The customer must use the MMU to prevent corruption.

Table 1-2 shows an overview of the device memory map. It is intended to illustrate how the crossbar switch integrates into the memory map.

Table 1-2. MPC5565 Memory Map (Single-Chip or Single-Master Mode)

Base Address	XBAR Slave Port	ADDR[0:2]	Size	Use
0x0000_0000	Flash	0b000	2 MB	Flash memory array
0x0020_0000	Reserved	0b000	14 MB–512 bytes	Reserved
0x00FF_FC00	Flash	0b000	1 KB	Flash shadow row
0x0100_0000			496 MB	Emulation mapping of flash
0x2000_0000	EBI and calibration ¹	0b001	512 MB ²	External bus interface
0x4000_0000	Internal SRAM	0b010	80 KB	Internal SRAM
0x4001_4000	Reserved	0b010	512 MB–80 KB	Reserved
0x6000_0000	Reserved	0b011– 0b101	1536 MB	Reserved
0xC000_0000	Reserved	0b011– 0b101	63 MB	Reserved
0xC3F0_0000	Bridge A peripherals	0b110	512 KB	Platform A peripherals
0xC3F8_0000			512 KB	
0xC400_0000	Reserved	0b110	512 MB–64 MB	Reserved
0xE000_0000	Reserved	0b111	512 MB–64 MB	Reserved
0xFC00_0000	Reserved	0b111	63 MB	Reserved
0xFFF0_0000	Bridge B peripherals	0b111	512 KB	Platform B peripherals
0xFFF8_0000		0b111	512 KB	

¹ One method is to assign 0x2000_0000 to 0x2FFF_FFFF to the EBI and assign 0x3000_0000 to 0x3FFF_FFFF to calibration. Hardware, however, does not force any restriction on EBI memory versus calibration memory.

² Using four chip select signals and 24 address bus signals, 64 MB can be mapped into the external memory space in single-master mode. Using four chip select signals and 26 address bus signals, 256 MB can be mapped into the external memory space in single-master mode.

Table 1-3 shows a detailed list of the device memory map.

Table 1-3. MPC5565 Detailed Memory Map

Address Range ¹	Allocated Size ¹ (Bytes)	Used Size (Bytes)	Use
0x0000_0000–0x001F_FFFF	2 MB	2.0 MB	Flash memory array
0x0020_0000–0x00FF_FBFF	14 MB–1 KB (flash shadow row)	N/A	Reserved
0x00FF_FC00–0x00FF_FFFF	1 KB	1 KB	Flash shadow row
0x0100_0000–0x1FFF_FFFF	496 MB	2 MB	Emulation mapping of flash array
0x2000_0000–0x3FFF_FFFF	512 MB	N/A	External memory ²
0x4000_0000–0x4000_7FFF	32 KB	32 KB	Internal SRAM array, standby powered

Table 1-3. MPC5565 Detailed Memory Map (continued)

Address Range ¹	Allocated Size ¹ (Bytes)	Used Size (Bytes)	Use
0x4000_8000–0x4001_3FFF	48 KB	48 KB	Internal SRAM array
0x4001_4000–0xBFFF_FFFF	2048 MB–80 KB (total SRAM)	N/A	Reserved
Bridge A Peripherals			
0xC000_0000–0xC3EF_FFFF	63 MB	N/A	Reserved
0xC3F0_0000–0xC3F0_3FFF	16 KB	—	Bridge A registers
0xC3F0_4000–0xC3F7_FFFF	496 KB	N/A	Reserved
0xC3F8_0000–0xC3F8_3FFF	16 KB	—	FMPLL registers
0xC3F8_4000–0xC3F8_7FFF	16 KB	48	External bus interface (EBI) configuration registers
0xC3F8_8000–0xC3F8_BFFF	16 KB	28	Flash configuration registers
0xC3F8_C000–0xC3F8_FFFF	16 KB	N/A	Reserved
0xC3F9_0000–0xC3F9_3FFF	16 KB	2.5 KB	System integration unit (SIU)
0xC3F9_4000–0xC3F9_FFFF	48 KB	N/A	Reserved
0xC3FA_0000–0xC3FA_3FFF	16 KB	1056	Modular input output timer system (eMIOS)
0xC3FA_4000–0xC3FB_FFFF	112 KB	N/A	Reserved
0xC3FC_0000–0xC3FC_3FFF	16 KB	3 KB	Enhanced time processing unit (eTPU) registers
0xC3FC_4000–0xC3FC_7FFF	16 KB	N/A	Reserved
0xC3FC_8000–0xC3FC_8BFF	16 KB	2.5 KB	eTPU shared data memory (parameter RAM)
0xC3FC_C000–0xC3FC_CBFF	16 KB	2.5 KB	eTPU shared data memory (parameter RAM) mirror
0xC3FD_0000–0xC3FD_2FFF	16 KB	12 KB	eTPU shared code RAM
0xC3FD_4000–0xC3FF_FFFF	176 KB	N/A	Reserved
0xC400_0000–0xDFFF_FFFF	512 MB–64 MB	N/A	Reserved
Bridge B Peripherals			
0xE000_0000–0xFBFF_FFFF	512 MB–64 MB	N/A	Reserved
0xFC00_0000–0xFFEF_FFFF	63 MB	N/A	Reserved
0xFFFF0_0000–0xFFFF0_3FFF	16 KB	N/A	Bridge B registers

0xFFFF0_8000–0xFFFF0_FFFF	32 KB	N/A	Reserved
0xFFFF1_0000–0xFFFF3_FFFF	192 KB	N/A	Reserved
0xFFFF4_0000–0xFFFF4_3FFF	16 KB	N/A	ECSM
0xFFFF4_4000–0xFFFF4_7FFF	16 KB	N/A	DMA controller 2 (eDMA)
0xFFFF4_8000–0xFFFF4_BFFF	16 KB	N/A	Interrupt controller (INTC)

Table 1-3. MPC5565 Detailed Memory Map (continued)

Address Range ¹	Allocated Size ¹ (Bytes)	Used Size (Bytes)	Use
0xFFFF4_C000–0xFFFF4_FFFF	16 KB	N/A	Reserved
0xFFFF5_0000–0xFFFF7_FFFF	192 KB	N/A	Reserved
0xFFFF8_0000–0xFFFF8_3FFF	16 KB	164	Enhanced queued analog-to-digital converter (eQADC)
0xFFFF8_4000–0xFFFF8_FFFF	48 KB	N/A	Reserved
0xFFFF9_0000–0xFFFF9_3FFF	16 KB	N/A	Reserved
0xFFFF9_4000–0xFFFF9_7FFF	16 KB	200	Deserial serial peripheral interface (DSPI B)
0xFFFF9_8000–0xFFFF9_BFFF	16 KB	200	Deserial serial peripheral interface (DSPI C)
0xFFFF9_C000–0xFFFF9_FFFF	16 KB	200	Deserial serial peripheral interface (DSPI D)
0xFFFFA_0000–0xFFFFA_FFFF	64 KB	N/A	Reserved
0xFFFFB_0000–0xFFFFB_3FFF	16 KB	44	Serial communications interface (eSCI A)
0xFFFFB_4000–0xFFFFB_7FFF	16 KB	44	Serial communications interface (eSCI B)
0xFFFFB_8000–0xFFFFB_FFFF	32 KB	N/A	Reserved
0xFFFFC_0000–0xFFFFC_3FFF	16 KB	1152	Controller area network (FlexCAN A)
0xFFFFC_4000–0xFFFFC_7FFF	16 KB	1152	Controller area network (FlexCAN B)
0xFFFFC_8000–0xFFFFC_BFFF	16 KB	1152	Controller area network (FlexCAN C)
0xFFFFC_C000–0xFFFFC_FFFF	16 KB	1152	Reserved
0xFFFFD_0000–0xFFFFD_3FFF	16 KB	1152	Reserved
0xFFFFD_4000–0xFFFFD_FFFF	80 KB	N/A	Reserved
0xFFFFE_0000–0xFFFFE_3FFF	16 KB	1152	Reserved
0xFFFFE_4000–0xFFFFE_7FFF	16 KB	N/A	Reserved
0xFFFFE_8000–0xFFFFE_BFFF	16 KB	1152	Reserved
0xFFFFE_0000–0xFFFFF_BFFF	64 KB	N/A	Reserved
0xFFFFF_0000–0xFFFFF_FFFF ³	16 KB	16 KB	Boot assist module (BAM)

¹ If the allocated size is more than the used size, then the base address for the module is the lowest address of the listed address range, unless noted otherwise.

² A suggested convention to follow is to place EBI from 0x2000_0000 to 0x2FFF_FFFF and to place calibration space from 0x3000_0000 to 0x3FFF_FFFF. Hardware, however, does not force any restriction on EBI versus calibration space.

³ BAM address range is configured so that 4 KB BAM occupies 0xFFFF_F000–0xFFFF_FFFF.

1.6 Multi-Master Operation Memory Map

NOTE

When multi-master mode is enabled, the bus is permanently granted to the external master; therefore, the MPC5565 MCU cannot be a master on a multi-master bus, only a slave.

When the MCU acts as a slave in a multi-master system, the external bus interface (EBI) translates the 24-bit external address to a 32-bit internal address. [Table 1-4](#) lists the translation parameters.

Table 1-4. External to Internal Memory Map Translation Table for Slave Mode

Ext Addr[8:11] ¹	Internal Address[0:11]	Bytes	Internal Slave	Internal Address Range
0b0xxx	N/A	8 MB	N/A	n/a. Off-chip flash access
0b10xx	0b0000_0000_00xx	4 MB	Internal flash array	0x0000_0000–0x003F_FFFF
0b1100	0b0100_0000_0000	1 MB	Internal SRAM	0x4000_0000–0x4000_FFFF
0b1101	0b0110_0000_0000	1 MB	Reserved ²	0x6000_0000–0x600F_FFFF
0b1110	0b1100_0011_1111	1 MB	Bridge A peripherals	0xC3F0_0000–0xC3FF_FFFF
0b1111	0b1111_1111_1111	1 MB	Bridge B peripherals	0xFFFF0_0000–0xFFFF_FFFF

¹ Only the lower 24 address signals (ADDR[8:31]) are available off-chip for external master accesses.

² Reserved for a future module that requires its own crossbar slave port.

[Table 1-5](#) shows the memory map for the MCU acting as a slave in a multi-master system from the point of view of the external master.

Table 1-5. MPC5565 Family Slave Memory Map as Seen from an External Master

External Address Range ¹	Size (bytes)	Use
0x0000_0000 ² –0x007F_FFFF	8 MB	n/a. Used for off-chip memory accesses
0x0080_0000–0x009F_FFFF	2 MB	Slave flash ³
0x00A0_0000–0x00BF_FFFF	2 MB	Reserved
0x00C0_0000–0x00C1_3FFF	80 KB	Slave internal SRAM
0x00C1_4000–0x00CF_FFFF	1 MB–80 KB (less total SRAM)	Reserved
0x00D0_0000–0x00DF_FFFF	1 MB	Reserved
0x00E0_0000–0x00EF_FFFF	1 MB	Slave bridge A peripherals
0x00F0_0000–0x00FF_FFFF	1 MB	Slave bridge B peripherals

¹ Only the lower 24 address signals (ADDR[8:31]) are available off-chip for external master accesses.

² This address range is not part of the MPC5500 family slave memory map, rather it is shown to illustrate the addressing scheme for off-chip accesses in multi-master mode.

³ The shadow row of the slave flash is not accessible by an external master.

1.7 Document Revision History

Table 1-6. Changes Between MPC5565RM Revisions 0.1 and 1

In Features, changed “Parallel programming mode to support rapid end of line programming” to “Page programming mode to support rapid end of line programming”
Figure 1-1 Changed SRAM to 80 KB, eQADC to 2.
Section 1.5, “MPC5500 Family Memory Map” Added the following text about reserved bits and memory: Reserved register bits are allocated for future products and have a default value of zero. When writing to a register, the reserved bits default values must be written as well. Most device features are activated by writing a non-zero value to them. Reserved memory is allocated for future products, therefore do not write to memory segments that are designated as reserved.
Section 1.2, “Features”: Added page footnote to read: Although this device has a maximum of 231 interrupts, the logic requires that the total number of interrupts be divisible by four. Therefore, the total number of interrupts specified for this device is 232. Added: Although this device is designed to support a 32-bit data bus, only 16-pins are available and connected on the 324 BGA package. (the 496-pin VertiCal assembly has the calibration functionality) to the subbullet 324 BGA: 16-bit data bus, 20-bit address bus is default, but configurable to 24-bit address bus under the External Bus Interface bullet in the features list.
Table 1-1 <i>MPC5500 Family Product Comparison</i> : Removed MPC5553 (Moccasin) and MPC5567 (Tiger) and left just MPC5554 (Copperhead) for comparison. Removed footnote 4: Select either ADDR[8:31] or ADDR[6:29] to configure a 24-bit address bus from the 32-bit EBI data bus row and added it on the address bus row. Added footnote 5 to the MPC5565 EBI data bus row that reads: The EBI is limited to a 16-bit data bus on the 324 package.

Chapter 2 Signal Description

This chapter describes the external device signals, including a table of signal properties, detailed descriptions of the available signals, and the I/O pin power/ground segmentation.

2.1 Block Diagram

To provide an extensive feature set as well as compatibility between the MPC5500 family of devices, the majority of balls are assigned multiplexed signal functions. [Figure 2-1](#) shows only the signals that are available on the device. Signal functions that are not available on this device are not shown in the diagram. Primary signal functions that are not available on the device but are used as pin labels in the Ball Grid Array (BGA) map are listed in [Table 2-2](#).

The 324 package has a limited number of balls which affects the following signals and features:

Table 2-1. MPC5565 324 Package Limitations

Feature Signals	MPC5565 Design	324 Package
Maximum 24-bit EBI address bus	ADDR[8:31]_GPIO[4:27]; ADDR[8:11] are muxed as alternate signals with the chip select signals CS[0:3]_ADDR[8:11]_GPIO[0:3]. ADDR[8:11] is also muxed with GPIO[4:7], providing four chip selects <i>and</i> 24-bit address bits.	ADDR[8:11]_GPIO[4:7] no balls available. Use CS[0:3]_ADDR[8:11]_GPIO[0:3] to choose between using chip select signals <i>or</i> maximizing the number of output address signals ADDR[8:31]_GPIO[0:3, 8:31] for a 24-bit EBI address bus.
Maximum 32-bits wide EBI data bus	DATA[0:31]_GPIO[28:59]	16 balls available for a 16-bits wide DATA[0:15]_GPIO[28:43]. There are no balls available for DATA[16:31]_GPIO[44:59].
Four EBI write enable/byte enable	WE/BE[0:3]	Only two balls available (WE/BE[0:1])
EBI transfer error acknowledge	TEA_GPIO[71]	No ball available
EBI bus busy	BB signal not available. GPIO is available.	BB_GPIO[72] no ball available
EBI bus grant	BG signal not available GPIO is available.	BG_GPIO[73] no ball available
EQADC Event trigger inputs 0 and 1	ETRIG[0:1]_GPIO[111:112]	No balls available
General Purpose Input/output	GPIO[205]	No ball available
Calibration bus	Calibration bus is separate from the EBI but uses the EBI controller. Refer to Figure 2-1 for the calibration bus signals.	No balls available. These signals are only available in the VertiCal assembly.

Refer to the last two columns in [Table 2-2](#) for a comparison of available signals on the 324 package compared to the VertiCal assembly.

NOTE

The Vertical assembly has ball connections for all the *available* signals on the device.

Signal Description

¹ The 324 package does not support all muxed signals designed for this device. Refer to Table 2-1 for a list of the signals that are not supported on the 324 package.

² The calibration signals only function when using the VertiCal assembly.

Figure 2-1. MPC5565 Signals

2.2 External Signal Descriptions

This section summarizes the external signal functions, their static electrical characteristics, and pad configuration settings for this device. The signal properties and their electrical characteristics are set in the System Integration Unit (SIU) Pad Configuration (PCR) registers.

Signal functions are multiplexed to each ball on the BGA in a function hierarchy: Primary, Main Primary, Alternate, Second Alternate, and General Purpose Input/Output (I/O). For example, in the signal PCSA[3]_SIND_GPIO[99], the primary signal function is PCSA[3], the first alternate signal function is SIND, and the GPIO function is a generic General Purpose I/O signal. Multiplexing signal functions allows for more flexibility when configuring the device, as well as providing compatibility with other devices in the MPC5500 product family.

The primary signal function name is used in the Ball Grid Array (BGA) map to identify the location of the ball, however, the primary signal function is not always valid for all devices. As shown in Figure 2-2, when the primary signal function is not available on the device, a dash appears in the following Signal table columns: Signal Functions, P/A/G, and I/O Type.

No primary function available

Table 4-1. Signal Properties

Signal Names	Signal Functions	P/A/G	I/O Type	Voltage	Pad Type	S
						During Reset
PCSA[3]_ ²¹ SIND_ GPIO[99]	— DSPI D data input GPIO	— A G	— I I/O	VDDEH6	MH	— / Up

Table Footnote

- Primary Functions are listed First
- Secondary Functions are alternate functions
- GPIO Functions are general functions listed Last

Figure 2-2. Primary Function Not Available on Device

The entries in the P/A/G column designate the position in the signal function hierarchy for multiplexed functions. These symbols correspond to binary values for the Pin Assignment (PA) field in the SIU_PCR registers that determine the active signal function. The PA field is from 1- to 3-bits wide, depending on the PCR register. Figure 2-3 explains the symbol definitions used in the P/A/G column for Table 2-2.

P/A/G Symbol	PA Function Type	PA Bits			# of <i>f</i> s
		3	4	5	
G	General purpose I/O	0	0	0	1-bit 2 <i>f</i> s
P	Primary	0	0	1	2-bits 4 <i>f</i> s
A	Alternate	0	1	0	
MP	Main	0	1	1	3-bits > 4 <i>f</i> s
A2	Second alternate	1	0	0	
All other values reserved for future use.		<i>n</i>	<i>n</i>	<i>n</i>	

Bit 3 in the SUI_PCR registers is bit 0 in the PA field.

PA[0:2]

Bit 5 in the SUI_PCR registers is bit 2 in the PA field.

The main function is used for device compatibility.

Figure 2-3. Understanding the P/A/G Column Entries

The following table lists the valid signal functions and their properties for this device:

Table 2-2. MPC5565 Signal Properties (continued)

Signal Names ¹	Signal Functions ²	P/ A/ G	I/O Type	Voltage ³	Pad Type ⁴	Status		324 Package	496 ⁵ VertiCal assembly
						During Reset ⁶	After Reset ⁷		
V _{SS}	MCU ground	P	—	—	—	N/A	V _{SS}	A1, A22, B2, B21, C3, C20, D4, D19, J9:13, K9:14, L9:14, M11:14 N9:10, N12:14, P9:10, P12:14, W4, W19, Y3, Y20, AA2, AA21, AB1, AB22	A1, A2, A27, A28, B1, B2, B27, B28, C3, C26, E5, E24, G7, G22, H8, H21, L11:14, M12:17, N14:17, P14:17, R14:16, T13, T16:17, U12, U17:18, V7, V18, AA8, AA21, AB7, AB22, AD5, AF3, AF26, AG1:2, AG27:28 AH1:2, AH27:28
No Connect									
NC ⁴⁰	No connect	N/A	N/A	N/A	N/A	N/A	N/A	W18, Y19	A19, B17:19, C17:19, E17:23, G16:21, H16:20, J22, J27:28, K21:22, K26:28, L22, L24, L26:27, M24, P2, R2, AA12, AG17

¹ Because more than one signal is often multiplexed to one pin, each line in the signal name column is a separate function. For all MPC5565 I/O pins the selection of the primary pin function, alternate function, or GPIO is determined in the SIU_PCR registers.

² Each line in the signal name column corresponds to a separate signal function on the pin. For all device I/O pins, the primary, alternate, or GPIO signal functions are designated in the PA field of the system integration unit (SIU) PCR registers except where explicitly noted.

³ V_{DDE} (fast I/O) and V_{DDEH} (slow I/O) power supply inputs are grouped into segments. Each segment of V_{DDEH} pins can connect to a separate 3.3–5.0 V (+5% and –10%) power supply input. Each segment of V_{DDE} pins can connect to a separate 1.8–3.3 V (±10%) power supply, with the exception of the V_{DDE2} and V_{DDE3} segments that are shorted together and must use the same power supply input. This segment is labeled V_{DDE2} in the BGA map.

⁴ The pad type is indicated by one of the abbreviations; F for fast, MH for medium (high voltage), SH for slow (high voltage), A for analog, AE for analog with ESD protection circuitry. Some pads have two types, depending on which pad function is selected.

- 5 The 496 assembly contains the VertiCal base and includes 324 pins.
- 6 The Status During Reset pin is sampled after the internal POR is negated. Prior to exiting POR, the signal has a high impedance. Terminology is O - output, I - input, Up - weak pullup enabled, Down - weak pulldown enabled, Low - output driven low, High - output driven high. A dash on the left side of the slash denotes that both the input and output buffers for the pin are off. A dash on the right side of the slash denotes that there is no weak pullup/down enabled on the pin. The signal name to the left or right of the slash indicates the pin is enabled.
- 7 Function after reset of GPI is general purpose input. A dash on the left side of the slash denotes that both the input and output buffers for the pin are off. A dash on the right side of the slash denotes that there is no weak pullup/down enabled on the pin.
- 8 Tie PLLCFG[2] to ground.
- 9 The EBI is specified and tested at 1.8–3.3 V.
- 10 Do not configure both the primary function in ADDR[8:11]_GPIO[4:7] and the secondary function in $\overline{CS}[0:3]_{_}ADDR[8:11]_{_}GPIO[0:3]$ pins to be the address input. Only configure one set of pins for the address input.
- 11 When using the EBI functions, select the function in the SIU_PCR register, and then enable the EBI functions in the EBI registers for these pins. Both the SIU and EBI configurations must match to operation correctly.
- 12 The function and state of this pin(s) after execution of the BAM program is determined by the BOOTCFG[0:1] pins. Refer to [Table 15-7](#) for detail on the External Bus Interface (EBI) configuration after execution of the BAM program.
- 13 These signals are not available on the 324 package.
- 14 The functions for the $\overline{WE}/\overline{BE}[0:1]_{_}GPIO[64:65]$ and $\overline{WE}/\overline{BE}[2:3]_{_}CAL_{_}\overline{WE}/\overline{BE}[0:1]_{_}GPIO[66:67]$ pins are specified in the SIU. When configured for EBI, the write enable or byte enable operation is specified in the EBI_BR0 through EBI_BR3 registers. When configured for the calibration bus, the write enable or byte enable operation is specified in the EBI_CAL_BR0 through EBI_CAL_BR3 registers for each chip select region.
- 15 The \overline{BR} and \overline{BG} primary signal functions are not implemented on the MPC5565 324 package, however the pin labels remain \overline{BR} and \overline{BG} on the BGA map of the 496 assembly.
- 16 These signals are available on the Vertical assembly only.
- 17 \overline{MCKO} is only enabled if debug mode is enabled. Debug mode can be enabled before or after exiting System Reset (\overline{RSTOUT} negated).
- 18 MDO[0] is driven high following a power-on reset until the system clock achieves lock, at which time it is then negated. There is an internal pullup on MDO[0].
- 19 The function of the MDO[11:4]_GPIO[82:75] pins is selected during a debug port reset by the \overline{EVTI} pin or by selecting FPM in the NPC_PCR. When functioning as MDO[11:4] the pad configuration specified by the SIU does not apply. Refer to 2.3.3.4 for more detail on MDO[11:4] pin operation.
- 20 The function and state of the FlexCAN A pins after execution of the BAM program is determined by the BOOTCFG[0:1] pins. Refer to [Table 15-9](#) for details on the FlexCAN pin configurations after the BAM executes.
- 21 The primary signal is not available on this device and is listed only for reference to the pin label in the BGA Map.
- 22 For compatibility to the MPC5554, always power V_{DDEH6} and V_{DDEH10} from the same power supply 3.0–5.25 V. To allow one DSPI to operate at a different operating voltage, connect V_{DDEH6} and V_{DDEH10} to separate power supplies, but this configuration is not compatible with the MPC5554.
- 23 All analog input channels are connected to both ADC blocks. The supply designation for this pin(s) specifies only the ESD rail used.
- 24 Because the primary signal function designations for the analog functions AN[12] through AN[15] are internally reserved, the PA field of the corresponding SIU_PCR registers must be set to the main primary function value of 0b011 to use analog functions AN[12] through AN[15].
- 25 To use the serial data strobe functions, the PA field in the SIU_PCR registers must be set to 0b00. Because \overline{SDS} , SDO, SDI, and FCK use the GPIO setting, a G is shown in the P/A/G column. However, these signals do not support GPIO functionality.
- 26 If analog features are used, tie V_{DDEH9} to V_{DDA1} .
- 27 Because other balls already are named EMIOS[14:15], the balls for these signals are named GPIO[203:204].
- 28 The GPIO[205] pin is a protect-for-pin for configuring an external boot for a double data rate (DDR) memory.
- 29 The GPIO[206:207] pins are protect-for-pins for double data rate (DDR) memory data strobes. These pins can be selected as the source for the eQADC trigger in the eQADC Trigger Input Select Register (SIU_ETISR).
- 30 The Function After Reset of the XTAL pin is determined by the value of the signal on the PLLCFG[1] pin. Ground the XTAL pin when using bypass mode.
- 31 When the FMPLL is configured for external reference mode, the V_{DDE5} supply affects the acceptable signal levels for the external reference. Refer to [Section 11.1.4.2, “External Reference Mode.”](#)
- 32 The function after reset of the EXTAL_EXTCLK pin is determined by the value of the signal on the PLLCFG[1] pin. The operating voltage for the EXTAL function is 3.3 V; the operating voltage for the EXTCLK function is 1.62–3.6 V.
- 33 V_{RC33} is the 3.3 V input for the voltage regulator control.
- 34 The V_{DDAn} and V_{SSAn} supply inputs are split into separate traces in the package substrate. Each trace is bonded to a separate pad location, which provides isolation between the analog and digital sections within each ADC.
- 35 Can be tied to 5.0 V for both read operation and program / erase.
- 36 Tie the V_{STBY} pin to V_{SSA0} if the battery backed SRAM is not used.
- 37 Both V_{DDE2} and V_{DDE3} pins are labeled as V_{DDE2} pins on the BGA maps. V_{DDE3} can be connected internally to V_{DDE2} .
- 38 The V_{DDEH9} segment can be powered by 3.0–5.0 V for mux addresses or SSI functions, however the V_{DDEH9} segment must comply with the V_{DDA1} specifications (4.5–5.25 V) for analog input functions.
- 39 All pins with pad type F (pad_fc) are driven to the high state if their V_{DDE} segment is powered before V_{DD33} .
- 40 The pins are reserved for the clock and inverted clock outputs for the DDR memory interface.

2.3 Detailed Signal Description

This section provides detailed descriptions of the signal functions available for the device.

2.3.1 Reset and Configuration Signals

2.3.1.1 External Reset Input RESET

The $\overline{\text{RESET}}$ input is asserted by an external device to reset the all modules of the device MCU. The $\overline{\text{RESET}}$ pin must be asserted during a power-on reset.

Refer to [Section 4.2.1, “Reset Input \(RESET\).”](#)

2.3.1.2 External Reset Output RSTOUT

The $\overline{\text{RSTOUT}}$ output is a push/pull output that is asserted during an internal device reset. The pin can also be asserted by software without causing an internal reset of the device MCU.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

NOTE

During a power-on-reset (POR), $\overline{\text{RSTOUT}}$ is tri-stated.

2.3.1.3 Phase Locked-Loop Configuration / External Interrupt Request / GPIO PLLCFG[0] $\overline{\text{IRQ}}[4]$ GPIO[208]

PLLCFG[0] $\overline{\text{IRQ}}[4]$ GPIO[208] are sampled on the negation of the $\overline{\text{RESET}}$ input pin, if the $\overline{\text{RSTCFG}}$ pin is asserted at that time. The values are used to configure the FMPLL mode of operation. The alternate function is an external interrupt request input.

2.3.1.4 Phase Locked-Loop Configuration / External Interrupt Request / DSPI / GPIO PLLCFG[1] $\overline{\text{IRQ}}[5]$ SOUTD GPIO[209]

PLLCFG[1] $\overline{\text{IRQ}}[5]$ SOUTD GPIO[209] — If the $\overline{\text{RSTCFG}}$ signal is asserted, these functions are sampled at that time when the $\overline{\text{RESET}}$ input pin negates. The values are used to configure the FMPLL operation mode. The alternate function is an external interrupt request input, and the second alternate function is the data output for the DSPI module D.

2.3.1.5 Phase Locked-Loop Configuration PLLCFG[2]

The MPC5565 does not use PLLCFG[2], therefore it must be tied low.

Refer to [Section 11.3.1.1, “Synthesizer Control Register \(FMPLL_SYNCNCR\).”](#)

2.3.1.6 Reset Configuration Input / GPIO RSTCFG_GPIO[210]

The $\overline{\text{RSTCFG}}$ input is used to enable the BOOTCFG[0:1] and PLLCFG[0:1] pins during reset. If $\overline{\text{RSTCFG}}$ is negated during reset, the BOOTCFG and PLLCFG pins are not sampled at the negation of $\overline{\text{RSTOUT}}$. In that case, the default values for BOOTCFG and PLLCFG are used. If $\overline{\text{RSTCFG}}$ is asserted during reset, the values on the BOOTCFG and PLLCFG pins are sampled and configure the boot and FMPLL modes.

2.3.1.7 Reset Configuration / External Interrupt Request / GPIO BOOTCFG[0:1]_IRQ[2:3]_GPIO[211:212]

BOOTCFG[0:1]_IRQ[2:3]_GPIO[211:212] are sampled on the negation of the $\overline{\text{RSTOUT}}$ pin, if the $\overline{\text{RSTCFG}}$ pin is asserted at that time. The values are used by the Boot Assist Module (BAM) program to determine the boot configuration of the device. The alternate functions are the external interrupt request inputs (IRQs).

2.3.1.8 Weak Pull Configuration / GPIO WKPCFG_GPIO[213]

WKPCFG_GPIO[213] determines whether specified eTPU and eMIOS pins are connected to a weak pullup or weak pulldown during and immediately after reset.

2.3.2 External Bus Interface (EBI) Signals

2.3.2.1 External Chip Selects / External Address / GPIO CS[0]_ADDR[8]_GPIO[0]

$\overline{\text{CS}}[0]_{\text{ADDR}}[8]_{\text{GPIO}}[0]$ is an external bus interface (EBI) chip select output signals. ADDR[8] is the alternate signal function and is an external bus address function.

2.3.2.2 External Chip Selects / External Address / GPIO CS[1:3]_ADDR[9:11]_GPIO[1:3]

$\overline{\text{CS}}[1:3]_{\text{ADDR}}[9:11]_{\text{GPIO}}[1:3]$ are the external bus interface (EBI) chip select output signals. The alternate function is the ADDR[9:11] and is an external bus address function.

2.3.2.3 External Address / GPIO ADDR[8:11]_GPIO[4:7]

ADDR[8:11]_GPIO[4:7] are the External Bus Interface (EBI) address signals. These signals are not supported in the 324 package.

2.3.2.4 External Address / GPIO ADDR[12:29]_GPIO[8:25]

ADDR[12:29]_GPIO[8:25] are the External Bus Interface (EBI) address signals.

**2.3.2.5 External Address / GPIO
ADDR[30:31]_GPIO[26:27]**

ADDR[30:31]_GPIO[26:27] are the EBI address signals.

**2.3.2.6 External Data / GPIO
DATA[0:15]_GPIO[28:43]**

DATA[0:15]_GPIO[28:43] are the EBI data signals.

**2.3.2.7 External Data / GPIO
DATA[16]__GPIO[44]**

DATA[16]_GPIO[44] is an EBI data signal. These signals are not supported in the 324 package.

**2.3.2.8 External Data / GPIO
DATA[17]_GPIO[45]**

DATA[17]_GPIO[45] is an EBI data signal. These signals are not supported in the 324 package.

**2.3.2.9 External Data / GPIO
DATA[18]_GPIO[46]**

DATA[18]_GPIO[46] is an EBI data signal. These signals are not supported in the 324 package.

**2.3.2.10 External Data / GPIO
DATA[19]_GPIO[47]**

DATA[19]_GPIO[47] is an EBI data signal. These signals are not supported in the 324 package.

**2.3.2.11 External Data / GPIO
DATA[20]__GPIO[48]**

DATA[20]_GPIO[48] is an EBI data signal. These signals are not supported in the 324 package.

**2.3.2.12 External Data / GPIO
DATA[21]_GPIO[49]**

DATA[21]_GPIO[49] is an EBI data signal. These signals are not supported in the 324 package.

**2.3.2.13 External Data / GPIO
DATA[22]_GPIO[50]**

DATA[22]_GPIO[50] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.14 External Data / GPIO DATA[23]_GPIO[51]

DATA[23]_GPIO[51] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.15 External Data / GPIO DATA[24]_GPIO[52]

DATA[24]_GPIO[52] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.16 External Data / GPIO DATA[25]_GPIO[53]

DATA[25]_GPIO[53] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.17 External Data / GPIO DATA[26]_GPIO[54]

DATA[26]_GPIO[54] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.18 External Data / GPIO DATA[27]_GPIO[55]

DATA[27]_GPIO[55] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.19 External Data / GPIO DATA[28]_GPIO[56]

DATA[28]_GPIO[56] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.20 External Data / GPIO DATA[29]_GPIO[57]

DATA[29]_GPIO[57] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.21 External Data / GPIO DATA[30]_GPIO[58]

DATA[30]_GPIO[58] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.22 External Data / GPIO DATA[31]_GPIO[59]

DATA[31]_GPIO[59] is an EBI data signal. These signals are not supported in the 324 package.

2.3.2.23 External Read/Write / GPIO
RD_ $\overline{\text{WR}}$ _GPIO[62]

RD_ $\overline{\text{WR}}$ _GPIO[62] indicates whether an external bus transfer is a read or write operation.

2.3.2.24 External Burst Data In Progress / GPIO
BDIP_ $\overline{\text{GPIO}}$ [63]

BDIP_ $\overline{\text{GPIO}}$ [63] indicates that an EBI burst transfer is in progress.

2.3.2.25 External Write/Byte Enable / GPIO
 $\overline{\text{WE/BE}}$ [0:3]_GPIO[64:67]

$\overline{\text{WE/BE}}$ [0:3]_GPIO[64:67] specify which data pins contain valid data for an external bus transfer. Only $\overline{\text{WE/BE}}$ [0:1]_GPIO[64:65] are supported on the 324 package.

2.3.2.26 External Output Enable / GPIO
 $\overline{\text{OE}}$ _GPIO[68]

$\overline{\text{OE}}$ _GPIO[68] indicates that the EBI is ready to accept read data.

2.3.2.27 External Transfer Start / GPIO
 $\overline{\text{TS}}$ _GPIO[69]

$\overline{\text{TS}}$ _GPIO[69] is asserted by the EBI owner to indicate the start of a transfer.

2.3.2.28 External Transfer Acknowledge / GPIO
 $\overline{\text{TA}}$ _GPIO[70]

$\overline{\text{TA}}$ _GPIO[70] is asserted by the EBI owner to acknowledge that the slave has completed the current transfer.

2.3.2.29 External Transfer Error Acknowledge / GPIO
 $\overline{\text{TEA}}$ _GPIO[71]

$\overline{\text{TEA}}$ _GPIO[71] indicates that an error occurred in the current external bus transfer. These signals are not supported in the 324 package.

2.3.2.30 External Bus Request / GPIO
 $\overline{\text{BR}}$ _GPIO[72]

$\overline{\text{BR}}$ _GPIO[72] is the bus request. Because the $\overline{\text{BR}}$ primary signal function is reserved on this device, there is no primary signal function for this ball. GPIO[72] pin has GPIO functionality only. These signals are not supported in the 324 package.

2.3.2.31 External Bus Grant / GPIO $\overline{\text{BG_GPIO}}[73]$

$\overline{\text{BG_GPIO}}[73]$ is the bus grant. Because the $\overline{\text{BG}}$ primary signal function is reserved on this device, there is no primary signal function for this ball. $\text{GPIO}[72]$ pin has GPIO functionality only. These signals are not supported in the 324 package.

2.3.3 Nexus Signals

2.3.3.1 Nexus Event In $\overline{\text{EVTI}}$

$\overline{\text{EVTI}}$ is an input that is read during a debug port reset to enable or disable the Nexus Auxiliary port for data trace. After reset, the $\overline{\text{EVTI}}$ pin is used to initiate program and data trace synchronization messages or generate a breakpoint.

2.3.3.2 Nexus Event Out $\overline{\text{EVTO}}$

$\overline{\text{EVTO}}$ is an output that provides timing to a development tool for a single watchpoint or breakpoint occurrence.

2.3.3.3 Nexus Message Clock Out MCKO

MCKO is a free running clock output to the development tools which is used for timing of the MDO and $\overline{\text{MSEO}}$ signals.

2.3.3.4 Nexus Message Data Out $\text{MDO}[0]$

$\text{MDO}[0]$ is a trace message output to the development tools. In addition, $\text{MDO}[0]$ indicates the lock status of the system clock following a power-on reset. $\text{MDO}[0]$ is driven high following a power-on-reset until the system clock achieves lock, at which time it is then negated. There is an internal pullup on $\text{MDO}[0]$.

2.3.3.5 Nexus Message Data Out $\text{MDO}[3:1]$

$\text{MDO}[3:1]$ are the trace message outputs to the development tools.

2.3.3.6 Nexus Message Data Out / GPIO $\text{MDO}[11:4]_{\text{GPIO}}[82:75]$

$\text{MDO}[11:4]_{\text{GPIO}}[82:75]$ are the trace message outputs to the development tools for full port mode. These pins function as GPIO when the Nexus port controller (NPC) operates in reduced port mode.

2.3.3.7 Nexus Message Start/End Out $\overline{\text{MSEO}}[1:0]$

$\overline{\text{MSEO}}[1:0]$ are outputs that indicate when messages start and end on the MDO pins.

2.3.3.8 Nexus Ready Output $\overline{\text{RDY}}$

$\overline{\text{RDY}}$ is an output that indicates to the development tools the data is ready to be read from or written to the Nexus read/write access registers.

2.3.4 JTAG Signals

2.3.4.1 JTAG Test Clock Input TCK

TCK provides the clock input for the on-chip test logic.

2.3.4.2 JTAG Test Data Input TDI

TDI provides the serial test instruction and data input for the on-chip test logic.

2.3.4.3 JTAG Test Data Output TDO

TDO provides the serial test data output for the on-chip test logic.

2.3.4.4 JTAG Test Mode Select Input TMS

TMS controls test mode operations for the on-chip test logic.

2.3.4.5 JTAG Compliance Input JCOMP

The JCOMP pin is used to enable the JTAG TAP controller.

2.3.4.6 Test Mode Enable Input $\overline{\text{TEST}}$

The $\overline{\text{TEST}}$ pin is used to place the chip in test mode. It must be negated for normal operation.

2.3.5 Controller Area Network (FlexCAN) Signals

2.3.5.1 FlexCAN A Transmit / eSCI Transmit / GPIO CNTXA_TXDA_GPIO[83]

CNTXA_TXDA_GPIO[83] is the transmit pin for the FlexCAN A module. The alternate function is the transmit pin for the eSCI A module.

2.3.5.2 FlexCAN A Receive / eSCI Receive / GPIO CNRXA_RXDA_GPIO[84]

CNRXA_RXDA_GPIO[84] is the receive pin for the FlexCAN A module. The alternate function is the receive pin for the eSCI A module.

2.3.5.3 FlexCAN B Transmit / DSPI C Chip Select / GPIO CNTXB_PCSC[3]_GPIO[85]

CNTXB_PCSC[3]_GPIO[85] is the transmit pin for the FlexCan B module. The alternate function is a peripheral chip select output for the DSPI C module.

2.3.5.4 FlexCAN B Receive / DSPI C Chip Select / GPIO CNRXB_PCSC[4]_GPIO[86]

CNRXB_PCSC[4]_GPIO[86] is the receive pin for the FlexCan B module. The alternate function is a peripheral chip select output for the DSPI C module.

2.3.5.5 FlexCAN C Transmit / DSPI D Chip Select / GPIO CNTXC_PCSD[3]_GPIO[87]

CNTXC_PCSD[3]_GPIO[87] is the transmit pin for the FlexCAN C module. The alternate function is PCSD[3], a peripheral chip select for the DSPI D module.

2.3.5.6 FlexCAN A Receive / DSPI D Chip Select / GPIO CNRXC_PCSD[4]_GPIO[88]

CNRXC_PCSD[4]_GPIO[88] is the receive pin for the FlexCAN C module. The alternate function is PCSD[4], a peripheral chip select for the DSPI D module.

2.3.6 Serial Communication Interface (eSCI) Signals

2.3.6.1 eSCI A Transmit / GPIO TXDA_GPIO[89]

TXDA_GPIO[89] is the transmit pin for the eSCI A module.

2.3.6.2 eSCI A Receive / GPIO RXDA_GPIO[90]

RXDA_GPIO[90] is the receive pin for the eSCI A module. The pin is an input only for the RXD function, but as GPIO the pin is input or output based on the SIU PCR configuration.

2.3.6.3 eSCI B Transmit / DSPI D Chip Select / GPIO TXDB_PCSD[1]_GPIO[91]

TXDB_PCSD[1]_GPIO[91] is the transmit pin for the eSCI B module. The alternate function is a peripheral chip select output for the DSPI D module.

2.3.6.4 eSCI B Receive / DSPI D Chip Select / GPIO RXDB_PCSD[5]_GPIO[92]

RXDB_PCSD[5]_GPIO[92] is the transmit pin for the eSCI B module. The secondary function is a peripheral chip select for the DSPI D module.

2.3.7 Deserial/Serial Peripheral Interface (DSPI) Signals

2.3.7.1 DSPI A Clock / DSPI C Chip Select / GPIO SCKA_PCSC[1]_GPIO[93]

SCKA_PCSC[1]_GPIO[93] — Because the SCKA primary signal function is reserved on this device, there is no primary signal function for this ball. The alternate signal function is the PCSC[1], a peripheral chip select for the DSPI C module and is available on this device.

2.3.7.2 DSPI A Data Input / DSPI C Chip Select / GPIO SINA_PCSC[2]_GPIO[94]

SINA_PCSC[2]_GPIO[94] — Because the SINA primary signal function is reserved on this device, there is no primary signal function for this ball. Therefore, the alternate signal function is the PCSC[2], a peripheral chip select for the DSPI C module and is available on this device.

2.3.7.3 DSPI A Data Output / DSPI C Chip Select / GPIO SOUTA_PCSC[5]_GPIO[95]

SOUTA_PCSC[5]_GPIO[95] — Because the SOUTA primary function is reserved on this device, there is no primary signal function for this ball. Therefore, the alternate function is the PCSC[5], a peripheral chip select for the DSPI C module and is available on this device.

2.3.7.4 DSPI A Chip Select / DSPI D Chip Select / GPIO PCSA[0]_PCSD[2]_GPIO[96]

PCSA[0]_PCSD[2]_GPIO[96] — Because the PCSA[0] primary function is reserved on this device, there is no primary signal function for this ball. Therefore, the alternate function is the PCSD[2], a peripheral chip select for the DSPI D module.

2.3.7.5 DSPI A Chip Select / DSPI B Chip Select / GPIO PCSA[1]_PCSB[2]_GPIO[97]

PCSA[1]_PCSB[2]_GPIO[97] — Because the PCSA[1] primary function is reserved on this device, there is no primary signal function for this ball. Therefore, the alternate function is the PCSB[2], a peripheral chip select for the DSPI B module.

2.3.7.6 DSPI A Chip Select / DSPI D Clock / GPIO PCSA[2]_SCKD_GPIO[98]

PCSA[2]_SCKD_GPIO[98] — Because the PCSA[2] primary function is reserved on this device, there is no primary signal function. Therefore, the alternate function is the SCKD, a DSPI clock pin for the DSPI D module.

2.3.7.7 DSPI A Chip Select / DSPI D Data Input / GPIO PCSA[3]_SIND_GPIO[99]

PCSA[3]_SIND_GPIO[99] — Because the PCSA[3] primary function is reserved on this device, there is no primary signal function. Therefore, the alternate function is the SIND, a data input pin for the DSPI D module.

2.3.7.8 DSPI A Chip Select / DSPI D Data Output / GPIO PCSA[4]_SOUTD_GPIO[100]

PCSA[4]_SOUTD_GPIO[100] — Because the PCSA[4] primary function is reserved on this device, there is no primary signal function. Therefore, the alternate function is the SOUTD, a data output pin for the DSPI D module.

2.3.7.9 DSPI A Chip Select / DSPI B Chip Select / GPIO PCSA[5]_PCSB[3]_GPIO[101]

PCSA[5]_PCSB[3]_GPIO[101] — Because the PCSA[5] primary function is reserved on this device, there is no primary signal function. Therefore, the alternate function is PCSB[3], a peripheral chip select output pin for the DSPI B module.

2.3.7.10 DSPI B Clock / DSPI C Chip Select / GPIO SCKB_PCSC[1]_GPIO[102]

SCKB_PCSC[1]_GPIO[102] — SCKB is the primary function, and is the SPI clock pin for the DSPI B module. The alternate function is PCSC[1], a chip select output for the DSPI C module.

**2.3.7.11 DSPI B Data Input / DSPI C Chip Select / GPIO
SINB_PCSC[2]_GPIO[103]**

SINB_PCSC[2]_GPIO[103] — SINB is the primary function and is the data input pin for the DSPI B module. The alternate function is a chip select output for the DSPI C module.

**2.3.7.12 DSPI B Data Output / DSPI C Chip Select / GPIO
SOUTB_PCSC[5]_GPIO[104]**

SOUTB_PCSC[5]_GPIO[104] — SOUTB is the primary function and is the data output pin for the DSPI B module. The alternate function is a chip select output for the DSPI C module.

**2.3.7.13 DSPI B Chip Select / DSPI D Chip Select / GPIO
PCSB[0]_PCSD[2]_GPIO[105]**

PCSB[0]_PCSD[2]_GPIO[105] — PCSB[0] is the primary function and is a DSPI B peripheral chip select output pin. It also is a Slave Select (\overline{SS}) input pin for the DSPI B module slave mode operation. The alternate function is PCSD[2] and is a chip select output for the DSPI D module.

**2.3.7.14 DSPI B Chip Select / DSPI D Chip Select / GPIO
PCSB[1]_PCSD[0]_GPIO[106]**

PCSB[1]_PCSD[0]_GPIO[106] — PCSB[1] is the primary a peripheral chip select output pin for the DSPI B module. The alternate function is PCSD[0] and is a DSPI D peripheral chip select output that also is a Slave Select (\overline{SS}) input pin for DSPI D module slave mode operation.

**2.3.7.15 DSPI B Chip Select / DSPI C Data Output / GPIO
PCSB[2]_SOUTC_GPIO[107]**

PCSB[2]_SOUTC_GPIO[107] — PCSB[2] is the primary function and is a peripheral chip select output pin for the DSPI B module. SOUTC is the alternate function and is the data output for the DSPI C module.

**2.3.7.16 DSPI B Chip Select / DSPI C Data Input / GPIO
PCSB[3]_SINC_GPIO[108]**

PCSB[3]_SINC_GPIO[108] — PCSB[3] is the primary function and is a peripheral chip select output pin for the DSPI B module. SINC is the alternate function and is the data input for the DSPI C module.

**2.3.7.17 DSPI B Chip Select / DSPI C Clock / GPIO
PCSB[4]_SCKC_GPIO[109]**

PCSB[4]_SCKC_GPIO[109] — PCSB[4] is the primary function and is a peripheral chip select output pin for the DSPI B module. SCKC is the alternate function and is the SPI clock for the DSPI C module.

2.3.7.18 DSPI B Chip Select / DSPI C Chip Select / GPIO PCSB[5]_PCSC[0]_GPIO[110]

PCSB[5]_PCSC[0]_GPIO[110] — PCSB[5] is the primary function and is a peripheral chip select output pin for the DSPI B module. PCSC[0] is the alternate function and is a DSPI C peripheral chip select output but also is a Slave Select (\overline{SS}) input pin for DSPI C module slave mode operation.

2.3.8 Enhanced Queued A/D Controller (eQADC) Signals

2.3.8.1 Analog Input / Differential Analog Input AN[0]_DAN0+

AN[0] is a single-ended analog input to the two on-chip ADCs. DAN0+ is the positive terminal of the differential analog input DAN0 (DAN0+ to DAN0-).

2.3.8.2 Analog Input / Differential Analog Input AN[1]_DAN0-

AN[1] is a single-ended analog input to the two on-chip ADCs. DAN0- is the negative terminal of the differential analog input DAN0 (DAN0+ to DAN0-).

2.3.8.3 Analog Input / Differential Analog Input AN[2]_DAN1+

AN[2] is a single-ended analog input to the two on-chip ADCs. DAN1+ is the positive terminal of the differential analog input DAN1 (DAN1+ to DAN1-).

2.3.8.4 Analog Input / Differential Analog Input AN[3]_DAN1-

AN[3] is a single-ended analog input to the two on-chip ADCs. DAN1- is the negative terminal of the differential analog input DAN1 (DAN1+ to DAN1-).

2.3.8.5 Analog Input / Differential Analog Input AN[4]_DAN2+

AN[4] is a single-ended analog input to the two on-chip ADCs. DAN2+ is the positive terminal of the differential analog input DAN2 (DAN2+ to DAN2-).

2.3.8.6 Analog Input / Differential Analog Input AN[5]_DAN2-

AN[5] is a single-ended analog input to the two on-chip ADCs. DAN2- is the negative terminal of the differential analog input DAN2 (DAN2+ to DAN2-).

**2.3.8.7 Analog Input / Differential Analog Input
AN[6]_DAN3+**

AN[6] is a single-ended analog input to the two on-chip ADCs. DAN3+ is the positive terminal of the differential analog input DAN3 (DAN3+ to DAN3-).

**2.3.8.8 Analog Input / Differential Analog Input
AN[7]_DAN3-**

AN[7] is a single-ended analog input to the two on-chip ADCs. DAN3- is the negative terminal of the differential analog input DAN3 (DAN3+ to DAN3-).

**2.3.8.9 Analog Input / Multiplexed Analog Input
AN[8]_ANW**

AN[8] is an analog input pin. ANW is an analog input in external multiplexed mode.

**2.3.8.10 Analog Input / Multiplexed Analog Input
AN[9]_ANX**

AN[9] is an analog input pin. ANX is an analog input in external multiplexed mode.

**2.3.8.11 Analog Input / Multiplexed Analog Input
AN[10]_ANY**

AN[10] is an analog input pin. ANY is an analog input in external multiplexed mode.

**2.3.8.12 Analog Input / Multiplexed Analog Input
AN[11]_ANZ**

AN[11] is an analog input pin. ANZ is an analog input in external multiplexed mode.

NOTE

Attempts to convert the input voltage applied to AN[12], AN[13], AN[14], and AN[15] while a non-eQADC function is selected causes an undefined conversion result.

**2.3.8.13 Analog Input / Mux Address 0 / eQADC Serial Data Strobe
AN[12]_MA[0]_SDS**

AN[12]_MA[0]_SDS is an analog input pin. The alternate function, MA[0], is a MUX address pin. SDS is the serial data strobe for the eQADC SSI; this function is selected by setting the PA field of SIU_PCR215 to GPIO. This pin has reduced analog to digital conversion accuracy as compared to the AN[0:7] and AN[16:39] analog input pins because they are powered by V_{DDEH9} and can be used as digital pins for the synchronous serial interface (SSI) to external ADCs or used as the multiplexor digital outputs (MA[0]).

$\overline{\text{SDS}}$ is the serial data select output that is muxed with AN[12] and MA[0]. It indicates to the external (slave) device when it can latch incoming serial data, when it can output its own serial data, and when it must abort a data transmission. $\overline{\text{SDS}}$ corresponds to the chip select signal in a conventional SPI interface.

This pin is configured by setting the pad configuration register, SIU_PCR215.

2.3.8.14 Analog Input / Mux Address 1 / eQADC Serial Data Out AN[13]_MA[1]_SDO

AN[13]_MA[1]_SDO is an analog input pin. The alternate function, MA[1], is a MUX address pin. SDO is the serial data output for the eQADC SSI; this function is selected by setting the PA field of SIU_PCR216 to GPIO. This pin has reduced analog to digital conversion accuracy as compared to the AN[0:7] and AN[16:39] analog input pins because they are powered by V_{DDEH9} and can be used as digital pins for the synchronous serial interface (SSI) to external ADCs or used as the multiplexor digital outputs (MA[1]).

This pin is configured by setting the pad configuration register, SIU_PCR216.

2.3.8.15 Analog Input / Mux Address 2 / eQADC Serial Data In AN[14]_MA[2]_SDI

AN[14]_MA[2]_SDI is an analog input pin. The alternate function, MA[2], is a MUX address pin. SDI is the serial data input for the eQADC SSI; this function is selected by setting the PA field of SIU_PCR217 to GPIO. This pin has reduced analog to digital conversion accuracy as compared to the AN[0:7] and AN[16:39] analog input pins because they are powered by V_{DDEH9} and can be used as digital pins for the synchronous serial interface (SSI) to external ADCs or used as the multiplexor digital outputs (MA[2]).

This pin is configured by setting the pad configuration register, SIU_PCR217.

2.3.8.16 Analog Input / eQADC Free Running Clock AN[15]_FCK

AN[15]_FCK is an analog input pin. The alternate function is the free running clock for the eQADC SSI. This pin has reduced analog to digital conversion accuracy as compared to the AN[0:7] and AN[16:39] analog input pins.

This pin is configured by setting the pad configuration register, SIU_PCR218.

2.3.8.17 Analog Input AN[16:39]

AN[16:39] are analog input pins.

2.3.8.18 External Trigger / GPIO ETRIG[0:1]_GPIO[111:112]

External trigger signals trigger a software or hardware event. The eQADC can detect rising edge, falling edge, high level, and low level on each of the external trigger signals. The eQADC also supports configurable digital filters for these external trigger signals.

The eQADC external trigger input pins can be connected to the eTPU, the eMIOS, or an external signal. The source is selected by configuring the eQADC trigger source in the SIU_ETISR register. Refer to [Table 6-132](#).

ETRIG[0] is the external trigger for CFIFO0, CFIFO2, and CFIFO4, and ETRIG[1] serves as the external trigger for CFIFO1, CFIFO3, and CFIFO5.

GPIO[111:112] are general purpose input/output functions.

These signals are not supported in the 324 package.

2.3.8.19 Voltage Reference High V_{RH}

V_{RH} is the voltage reference high input pin for the eQADC.

2.3.8.20 Voltage Reference Low V_{RL}

V_{RL} is the voltage reference low input pin for the eQADC.

2.3.8.21 Reference Bypass Capacitor REFBYPC

REFBYPC is a bypass capacitor input for the eQADC. The REFBYPC pin is used to connect an external bias capacitor between the REFBYPC pin and V_{RL} . The value of this capacitor must be 100nF. This bypass capacitor is used to provide a stable reference voltage for the ADC.

2.3.9 Enhanced Time Processing Unit (eTPU) Signals

2.3.9.1 eTPU A TCR Clock / External Interrupt Request / GPIO TCRCLKA_ \overline{IRQ} [7]_GPIO[113]

TCRCLKA_ \overline{IRQ} [7]_GPIO[113] is the TCR clock input for the eTPU A module. The alternate function is an external interrupt request input for the SIU module.

2.3.9.2 eTPU A Channel / eTPU A Channel (Output Only) / GPIO ETPUA[0]_ETPUA[12]_GPIO[114]

ETPUA[0]_ETPUA[12]_GPIO[114] is an input/output channel pin for the eTPU A module. ETPUA[0] is the primary function and is an input/output channel for the eTPU A module. The alternate function, ETPUA[12], is an output channel for the eTPU A module. When configured as ETPUA[12], the pin functions as output only. ETPUA[12] is an alternate function and is only for eTPU A module output channels.

2.3.9.3 eTPU A Channel / eTPU A Channel (Output Only) / GPIO ETPUA[1]_ETPUA[13]_GPIO[115]

ETPUA[1]_ETPUA[13]_GPIO[115] is an input/output channel pin for the eTPU A module. ETPUA[1] is the primary function and is an input/output channel for the eTPU A module. The alternate function, ETPUA[13], is an output channel for the eTPU A module. When configured as ETPUA[13], the pin functions as output only.

2.3.9.4 eTPU A Channel / eTPU A Channel (Output Only) / GPIO ETPUA[2]_ETPUA[14]_GPIO[116]

ETPUA[2]_ETPUA[14]_GPIO[116] is an input/output channel pin for the eTPU A module. ETPUA[2] is the primary functions and is an input/output channel for the eTPU A module. The alternate function is an output channel for the eTPU A module. When configured as ETPUA[14], the pin functions as output only.

2.3.9.5 eTPU A Channel / eTPU A Channel (Output Only) / GPIO ETPUA[3]_ETPUA[15]_GPIO[117]

ETPUA[3]_ETPUA[15]_GPIO[117] is an input/output channel pin for the eTPU A module. ETPUA[3] is the primary functions and is an input/output channel for the eTPU A module. The alternate function is an output channel for the eTPU A module. When configured as ETPUA[15], the pin functions as output only.

2.3.9.6 eTPU A Channel / eTPU A Channel (Output Only) / GPIO ETPUA[4]_ETPUA[16]_GPIO[118]

ETPUA[4]_ETPUA[16]_GPIO[118] is an input/output channel pin for the eTPU A module. The alternate function, ETPUA[16], is an output channel for the eTPU A module. When configured as ETPUA[16], the pin functions as output only.

2.3.9.7 eTPU A Channel / eTPU A Channel (Output Only) / GPIO ETPUA[5]_ETPUA[17]_GPIO[119]

ETPUA[5]_ETPUA[17]_GPIO[119] is an input/output channel pin for the eTPU A module. The alternate function, ETPUA[17], is an output channel for the eTPU A module. When configured as ETPUA[17], the pin functions as output only.

**2.3.9.8 eTPU A Channel / eTPU A Channel (Output Only) / GPIO
ETPUA[6]_ETPUA[18]_GPIO[120]**

ETPUA[6]_ETPUA[18]_GPIO[120] is an input/output channel pin for the eTPU A module. The alternate function, ETPUA[18], is an output channel for the eTPU A module. When configured as ETPUA[18], the pin functions as output only.

**2.3.9.9 eTPU A Channel / eTPU A Channel (Output Only) / GPIO
ETPUA[7]_ETPUA[19]_GPIO[121]**

ETPUA[7]_ETPUA[19]_GPIO[121] is an input/output channel pin for the eTPU A module. The alternate function, ETPUA[19], is an output channel for the eTPU A module. When configured as ETPUA[19], the pin functions as output only.

**2.3.9.10 eTPU A Channel / eTPU A Channel (Output Only) / GPIO
ETPUA[8]_ETPUA[20]_GPIO[122]**

ETPUA[8]_ETPUA[20]_GPIO[122] is an input/output channel pin for the eTPU A module. The alternate function, ETPUA[20], is an output channel for the eTPU A module. When configured as ETPUA[20], the pin functions as output only.

**2.3.9.11 eTPU A Channel / eTPU A Channel (Output Only) / GPIO
ETPUA[9]_ETPUA[21]_GPIO[123]**

ETPUA[9]_ETPUA[21]_GPIO[123] is an input/output channel pin for the eTPU A module. The alternate function, ETPUA[21], is an output channel for the eTPU A module. When configured as ETPUA[21], the pin functions as output only.

**2.3.9.12 eTPU A Channel / eTPU A Channel (Output Only) / GPIO
ETPUA[10]_ETPUA[22]_GPIO[124]**

ETPUA[10]_ETPUA[22]_GPIO[124] is an input/output channel pin for the eTPU A module. The alternate function, ETPUA[22], is an output channel for the eTPU A module. When configured as ETPUA[22], the pin functions as output only.

**2.3.9.13 eTPU A Channel / eTPU A Channel (Output Only) / GPIO
ETPUA[11]_ETPUA[23]_GPIO[125]**

ETPUA[11]_ETPUA[23]_GPIO[125] is an input/output channel pin for the eTPU A module. The alternate function, ETPUA[23], is an output channel for the eTPU A module. When configured as ETPUA[23], the pin functions as output only.

**2.3.9.14 eTPU A Channel / DSPI B Chip Select / GPIO
ETPUA[12]_PCSB[1]_GPIO[126]**

ETPUA[12]_PCSB[1]_GPIO[126] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI B module.

2.3.9.15 eTPU A Channel / DSPI B Chip Select / GPIO ETPUA[13]_PCSB[3]_GPIO[127]

ETPUA[13]_PCSB[3]_GPIO[127] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI B module.

2.3.9.16 eTPU A Channel / DSPI B Chip Select / GPIO ETPUA[14]_PCSB[4]_GPIO[128]

ETPUA[14]_PCSB[4]_GPIO[128] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI B module.

2.3.9.17 eTPU A Channel / DSPI B Chip Select / GPIO ETPUA[15]_PCSB[5]_GPIO[129]

ETPUA[15]_PCSB[5]_GPIO[129] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI B module.

2.3.9.18 eTPU A Channel / DSPI D Chip Select / GPIO ETPUA[16]_PCSD[1]_GPIO[130]

ETPUA[16]_PCSD[1]_GPIO[130] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI D module.

2.3.9.19 eTPU A Channel / DSPI D Chip Select / GPIO ETPUA[17]_PCSD[2]_GPIO[131]

ETPUA[17]_PCSD[2]_GPIO[131] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI D module.

2.3.9.20 eTPU A Channel / DSPI D Chip Select / GPIO ETPUA[18]_PCSD[3]_GPIO[132]

ETPUA[18]_PCSD[3]_GPIO[132] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI D module.

2.3.9.21 eTPU A Channel / DSPI D Chip Select / GPIO ETPUA[19]_PCSD[4]_GPIO[133]

ETPUA[19]_PCSD[4]_GPIO[133] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI D module.

2.3.9.22 eTPU A Channel / External Interrupt / GPIO ETPUA[20]_IRQ[8]_GPIO[134]

ETPUA[20]_IRQ[8]_GPIO[134] is an input/output channel pin for the eTPU A module. The alternate functions are an external interrupt request inputs for the SIU module.

**2.3.9.23 eTPU A Channel / External Interrupt / GPIO
ETPUA[21]_IRQ[9]_GPIO[135]**

ETPUA[21]_IRQ[9]_GPIO[135] is an input/output channel pin for the eTPU A module. The alternate functions are an external interrupt request inputs for the SIU module.

**2.3.9.24 eTPU A Channel / External Interrupt / GPIO
ETPUA[22]_IRQ[10]_GPIO[136]**

ETPUA[22]_IRQ[10]_GPIO[136] is an input/output channel pin for the eTPU A module. The alternate functions are an external interrupt request inputs for the SIU module.

**2.3.9.25 eTPU A Channel / External Interrupt / GPIO
ETPUA[23]_IRQ[11]_GPIO[137]**

ETPUA[23]_IRQ[11]_GPIO[137] is an input/output channel pin for the eTPU A module. The alternate functions are an external interrupt request inputs for the SIU module.

**2.3.9.26 eTPU A Channel (Output Only) / External Interrupt / GPIO
ETPUA[24:27]_IRQ[12:15]_GPIO[138:141]**

ETPUA[24:27]_IRQ[12:15]_GPIO[138:141] are output channel pins for the eTPU A module. The alternate function is external interrupt request inputs for the SIU module.

**2.3.9.27 eTPU A Channel (Output Only) / DSPI C Chip Select / GPIO
ETPUA[28]_PCSC[1]_GPIO[142]**

ETPUA[28]_PCSC[1]_GPIO[142] is an output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI C module.

**2.3.9.28 eTPU A Channel (Output Only) / DSPI C Chip Select / GPIO
ETPUA[29]_PCSC[2]_GPIO[143]**

ETPUA[29]_PCSC[2]_GPIO[143] is an output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI C module.

**2.3.9.29 eTPU A Channel / DSPI C Chip Select / GPIO
ETPUA[30]_PCSC[3]_GPIO[144]**

ETPUA[30]_PCSC[3]_GPIO[144] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI C module.

**2.3.9.30 eTPU A Channel / DSPI C Chip Select / GPIO
ETPUA[31]_PCSC[4]_GPIO[145]**

ETPUA[31]_PCSC[4]_GPIO[145] is an input/output channel pin for the eTPU A module. The alternate function is a peripheral chip select for the DSPI C module.

2.3.10 Enhanced Management Input/Output System (eMIOS) Signals

2.3.10.1 eMIOS Channel / eTPU A Channel (Output Only) / GPIO EMIOS[0:9]_ETPUA[0:9]_GPIO[179:188]

EMIOS[0:9]_ETPUA[0:9]_GPIO[179:188] is an input/output channel pin for the eMIOS module. The alternate function is output channels for the eTPU A module; that is, when configured as ETPUA[0:9], the pins function as outputs only.

2.3.10.2 eMIOS Channel / DSPI D Chip Select / GPIO EMIOS[10:11]_PCSD[3:4]_GPIO[189:190]

EMIOS[10:11]_PCSD[3:4]_GPIO[189:190] is an input/output channel pin for the eMIOS module. PCSD[3:4]_ is the alternate function is a peripheral chip select for the DSPI D module.

2.3.10.3 eMIOS Channel (Output Only) / DSPI C Data Output / GPIO EMIOS[12]_SOUTC_GPIO[191]

EMIOS[12]_SOUTC_GPIO[191] is an output channel pin for the eMIOS module. The alternate function is the data output for the DSPI C module.

2.3.10.4 eMIOS Channel (Output Only) / DSPI D Data Output / GPIO EMIOS[13]_SOUTD_GPIO[192]

EMIOS[13]_SOUTD_GPIO[192] is an output channel pin for the eMIOS module. The alternate function is the data output for the DSPI D module.

2.3.10.5 eMIOS Channel (Output Only) / External Interrupt Request / GPIO EMIOS[14]_ $\overline{\text{IRQ}}[0]$ _GPIO[193]

EMIOS[14]_ $\overline{\text{IRQ}}[0]$ _GPIO[193] is an output channel pin for the eMIOS module. The alternate function is an external interrupt request input.

2.3.10.6 eMIOS Channel (Output Only) / External Interrupt Request / GPIO EMIOS[15]_ $\overline{\text{IRQ}}[1]$ _GPIO[194]

EMIOS[15]_ $\overline{\text{IRQ}}[1]$ _GPIO[194] is an output channel pin for the eMIOS module. The alternate function is an external interrupt request input.

2.3.10.7 eMIOS Channel / GPIO EMIOS[16]_GPIO[195]

EMIOS[16]_GPIO[195] is an input/output channel pin for the eMIOS module.

**2.3.10.8 eMIOS Channel / GPIO
EMIOS[17]_GPIO[196]**

EMIOS[17]_GPIO[196] is an input/output channel pin for the eMIOS module.

**2.3.10.9 eMIOS Channel / GPIO
EMIOS[18]_GPIO[197]**

EMIOS[18]_GPIO[197] is an input/output channel pin for the eMIOS module.

**2.3.10.10 eMIOS Channel / GPIO
EMIOS[19]_GPIO[198]**

EMIOS[19]_GPIO[198] is an input/output channel pin for the eMIOS module.

**2.3.10.11 eMIOS Channel / GPIO
EMIOS[20:21]_GPIO[199:200]**

EMIOS[20:21]_GPIO[199:200] is an input/output channel pin for the eMIOS module.

**2.3.10.12 eMIOS Channel / GPIO
EMIOS[22]_GPIO[201]**

EMIOS[22]_GPIO[201] is an input/output channel pin for the eMIOS module.

**2.3.10.13 eMIOS Channel / GPIO
EMIOS[23]_GPIO[202]**

EMIOS[23]_GPIO[202] is an input/output channel pin for the eMIOS module.

2.3.11 General Purpose Input / Output (GPIO) Signals

**2.3.11.1 eMIOS Channel (Output Only) / GPIO
EMIOS[14:15]_GPIO[203:204]**

The EMIOS[14:15]_GPIO[203:204] pins' primary function is EMIOS[14:15]. When configured as EMIOS[14:15], the pins function as output channels for the eMIOS module. Because other balls on the BGA map are already named EMIOS[14:15], the ball names on the BGA map for these signals are named GPIO[203:204]. The general purpose I/O function for these pins is GPIO.

**2.3.11.2 General Purpose Input Output
GPIO[205]**

The GPIO[205] only has GPIO functionality. This pin is reserved for double data rate memory interface support. The pad type for GPIO[205] is MH (3.0–5.5 V). This signal is not supported in the 324 package.

2.3.11.3 General Purpose Input Output GPIO[206:207]

GPIO[206:207] have GPIO functionality. The GPIO pins are reserved for double data rate memory (DDRAM) interface support. The pad types for GPIO[206:207] are F (1.62–3.6 V).

Refer to [Section 6.3.1.108, “Pad Configuration Registers 206–207 \(SIU_PCR206–SIU_PCR207\).”](#)

The GPIO[206:207] pins can be selected as sources for the ADC trigger in the SIU_ETISR.

2.3.12 Calibration Bus Signals

Calibration signals function only when using the 496 pin assembly.

2.3.12.1 Calibration Chip Select 0 / GPIO CAL_CS[0]

CAL_CS[0] is the primary function and selects the primary chip for calibration. It is functional only when using the 496 pin assembly.

2.3.12.2 Calibration Chip Select / Calibration Address CAL_CS[2:3]_CAL_ADDR[10:11]

CAL_CS[2:3] are calibration chip selects and are the primary functions. CAL_ADDR[10:11] are the alternate functions and are calibration addresses. It is functional only when using the 496 pin assembly.

2.3.12.3 Calibration Address CAL_ADDR[12:30]

CAL_ADDR[12:30] are the calibration addresses. They are functional only when using the 496 pin assembly.

2.3.12.4 Calibration Data CAL_DATA[0:15]

CAL_DATA[0:15] is the primary function and is a calibration address. It is only functional on the 496 assembly.

2.3.12.5 Calibration Read/Write CAL_RD_WR

CAL_RD_WR is the primary function and is a calibration read/write signal function. It is only functional on the 496 assembly.

2.3.12.6 Calibration Write/Byte Enable CAL_ $\overline{\text{WE/BE}}$ [0:1]

CAL_ $\overline{\text{WE/BE}}$ [0:1] is the primary function and is a calibration write enable and byte enable. It is only functional on the 496 assembly.

2.3.12.7 Calibration Output Enable CAL_ $\overline{\text{OE}}$

CAL_ $\overline{\text{OE}}$ is the primary function and is a calibration output enable. It is only functional on the 496 assembly.

2.3.12.8 Calibration Transfer Start CAL_ $\overline{\text{TS}}$

CAL_ $\overline{\text{TS}}$ is the primary function and is a calibration transfer start. It is only functional on the 496 assembly.

2.3.13 Clock Synthesizer Signals

2.3.13.1 Crystal Oscillator Output XTAL

XTAL is the output pin for an external crystal oscillator.

2.3.13.2 Crystal Oscillator Input / External Clock Input EXTAL_EXTCLK

EXTAL is the input pin for an external crystal oscillator or an external clock source. The alternate function is the external clock input. The function of this pin is determined by the PLLCFG configuration pins.

2.3.13.3 System Clock Output CLKOUT

CLKOUT is the device system clock output.

2.3.13.4 Engineering Clock Output ENGCLK

ENGCLK is a 50% duty cycle output clock with a maximum frequency of the device system clock divided by two. ENGCLK is not synchronous to CLKOUT.

2.3.14 Power / Ground Signals

2.3.14.1 Voltage Regulator Control Supply Input

V_{RC33}

V_{RC33} is the 3.3 V supply input pin for the on-chip 1.5 V regulator control circuit.

2.3.14.2 Voltage Regulator Control Output

V_{RCCTL}

V_{RCCTL} is the output pin for the on-chip 1.5 V regulator control circuit.

2.3.14.3 eQADC Analog Supply

V_{DDAn}

V_{DDAn} is the analog supply input pin for the eQADC.

2.3.14.4 eQADC Analog Ground Reference

V_{SSAn}

V_{SSAn} is the analog ground reference input pin for the eQADC.

2.3.14.5 Clock Synthesizer Power Input

V_{DDSYN}

V_{DDSYN} is the power supply input for the FMPLL.

2.3.14.6 Clock Synthesizer Ground Input

V_{SSSYN}

V_{SSSYN} is the ground reference input for the FMPLL.

2.3.14.7 Flash Read Supply Input

V_{FLASH}

V_{FLASH} is the on-chip Flash read supply input.

2.3.14.8 Flash Program/Erase Supply Input

V_{PP}

V_{PP} is the on-chip flash program/erase supply input.

2.3.14.9 SRAM Standby Power Input

V_{STBY}

V_{STBY} is the power supply input that is used to maintain a portion of the contents of internal SRAM during power down. If not used, tie V_{STBY} to V_{SS} .

2.3.14.10 Internal Logic Supply Input

V_{DD}

V_{DD} is the 1.5 V logic supply input.

2.3.14.11 External I/O Supply Input

V_{DDEn}

V_{DDEn} is the 1.8–3.3 V, with a tolerance of +/- 10% external I/O supply input.

2.3.14.12 External I/O Supply Input

V_{DDEHn}

V_{DDEHn} is the 3.3–5.0 V, with a tolerance of -10% to +5% external I/O supply input.

2.3.14.13 Fixed 3.3 V Internal Supply Input

V_{DD33}

V_{DD33} is the 3.3 V internal supply input.

2.3.14.14 Ground

V_{SS}

V_{SS} is the ground reference input.

2.3.15 I/O Power and Ground Segmentation

Table 2-3 gives the preliminary power/ground segmentation. Each segment provides the power and ground for the I/O pins and can be powered by any voltage within the allowed voltage range regardless of the power on the other segments. The power/ground segmentation applies regardless of whether a particular pin is configured for its primary function or GPIO.

Table 2-3. MPC5565 Power / Ground Segmentation for 324 Pin Package

Power Segment	Voltage Range ¹	I/O Pins Powered by Segment
V_{DDA0}	5.0 V	AN[22:35]
V_{DDA1}	5.0 V	AN[0]_DAN0+, AN[1]_DAN0-, AN[2]_DAN1+, AN[3]_DAN1-, AN[4]_DAN2+, AN[5]_DAN2-, AN[6]_DAN3+, AN[7]_DAN3-, AN[8]_ANW, AN[9]_ANX, AN[10]_ANY, AN[11]_ANZ, AN[16:21], AN[36:39]
V_{SSA0}	GND	—
V_{SSA1}	GND	—
V_{DDE2}	1.8–3.3 V	$\overline{CS}[0]_{_ADDR[8]_{_GPIO[0]}}$, $\overline{CS}[2:3]_{_ADDR[10:11]_{_GPIO[2:3]}}$, ADDR[12:31]_GPIO[4:27], RD_WR_GPIO[62], $\overline{BDIP}_{GPIO[63]}$, $\overline{WE/BE}[0:1]_{_GPIO[64:65]}$, $\overline{TS}_{GPIO[69]}$, $\overline{TA}_{GPIO[70]}$
V_{DDE3} ²	1.8–3.3 V	DATA[0:15]_GPIO[28:43], $\overline{OE}_{GPIO[68]}$, GPIO[206:207]
V_{DDE5}	1.8–3.3 V	CLKOUT, ENGCLK

Table 2-3. MPC5565 Power / Ground Segmentation for 324 Pin Package (continued)

Power Segment	Voltage Range ¹	I/O Pins Powered by Segment
V _{DDE7}	1.8–3.3 V	\overline{EVTI} , $\overline{EVT0}$, MCKO, MDO[3:0], MDO[11:4]_GPIO[82:75], \overline{MSEO} [1:0], \overline{RDY} , TCK, TDI, TDO, TMS, JCOMP, \overline{TEST}

² During read operations, V_{PP} can be as high as 5.3 V or as low as 3.0 V.

2.4 eTPU Pin Connections and Serialization

2.4.1 ETPUA[0:15]

The ETPUA[0:15] module channels connect to external pins or can be serialized out through the DSPI C module. The full list of connections is given in [Table 2-5](#). Although not shown in [Figure 2-4](#), the output channels of ETPUA[12:15] are connected to the ETPUA[0:3]_ETPUA[12:15]_GPIO[114:117] pins.

The eTPU TCRA clock input is connected to an external pin only.

A diagram for the ETPUA[0:15] to SOUTC connection is given in [Figure 2-4](#).

2.4.2 ETPUA[16:31]

ETPUA[16:23,30:31] connect to external pins for both the input and output function. ETPUA[16:21,24:29] are serialized out on the DSPI B and DSPI D modules and ETPUA[22:23,30:31] are not serialized out. ETPUA[24:29] connect to external pins for only the output function. [Figure 2-5](#) shows the connections for ETPUA16 and applies to ETPUA[16:21]. [Figure 2-6](#) shows the connections for ETPUA24 and applies to TPUA[24:29]. The full ETPUA to DSPI B connections are given in [Table 2-6](#), and ETPU A to DSPI D in [Table 2-7](#). Although not shown in [Figure 2-5](#), the output channels of ETPUA[16:23] are also connected to the ETPUA[4:11]_ETPUA[16:23]_GPIO[118:125] pins.

2.5 eMIOS Pin Connections and Serialization

The eMIOS channels connect to external pins or can be serialized in and out of the device. Both the input and output channels of EMIOS[0:11, 16:23] connect to pins, but only the output channels of EMIOS[12:15] connect to pins. The output channels of EMIOS[10:13] can be serialized OUT, and the inputs of EMIOS[12:15] can be serialized IN. The DSPI connections for EMIOS[10:11] are given in [Figure 2-7](#), [Figure 2-8](#) for EMIOS[12:13], and [Figure 2-9](#) for EMIOS[14:15].

2.6 Document Revision History

Table 2-8. Changes Between MPC5565RM Revisions 0.1 and 1

<p>Table 2-2 <i>MPC5565 Signal Descriptions</i>: Added the phrase V_{DDE3} can be connected internally to V_{DDE2} to footnote 34.</p>
<p>First sentence in the EVTI signal description changed to: $\overline{\text{EVTI}}$ is an input that is read during a debug port reset to enable or disable the Nexus Auxiliary port (for trace).</p>
<p>Table 2-3 and Table 2-4 (<i>MPC5565 Power / Ground Segmentation</i> tables): Changed footnote 1 to start with “These are nominal voltages. Changed the V_{DDE} supplies to $\pm 10\%$; the V_{DDEH} supplies are $+5\%$ to -10%.”</p> <p>Additional changes are:</p> <ul style="list-style-type: none"> For REFBYPC, V_{RL}, and V_{RH}, placed a “–” in the Voltage cell of the signal table. These are independent of supply and clamp to the global VSS. Added footnote 23. Table 2-2 <i>MPC5565 Signal Descriptions</i>: Added TXDA and RXDA to CNTXA_GPIO[83] and CNRXA_GPIO[84] signals respectively. Table 2-3 <i>MPC5565 Power / Ground Segmentation for the 324 Package</i>: Added TXDA and RXDA to CNTXA_GPIO[83] and CNRXA_GPIO[84] signals respectively. Table 2-4 <i>MPC5565 Power / Ground Segmentation for the 496 Assembly</i>: Added TXDA and RXDA to CNTXA_GPIO[83] and CNRXA_GPIO[84] signals respectively.
<p>Added information on the differences between the device design and the 324 package limitations.</p> <p>In Section 2.1, “Block Diagram,” added Table 2-1 MPC5565 324 Package Limitations. Added sentence and note after Table 2-1 that reads:</p> <p>Refer to the last two columns in Table 2-2 for a comparison of available signals on the 324 package compared to the VertiCal assembly.</p> <p style="text-align: center;">NOTE</p> <p>The Vertical assembly has ball connections for all the <i>available</i> signals on the device.</p>
<p>Added two footnotes in Figure 2-1, <i>MPC5565 Signal Diagram</i>:</p> <p>¹ The 324 package does not support all muxed signals designed for this device. Refer to Table 2-1 for a list of the signals that are not supported on the 324 package.</p> <p>² The calibration signals only function when using the VertiCal assembly.</p> <p>Put footnote 1 in the diagram next to all signals from Table 2-1 <i>MPC5565 324 Package Limitations</i> except for the calibration signals. Put footnote 2 in the diagram next to all the calibration signals.</p>
<p>Table 2-2 <i>MPC5565 Signal Descriptions</i>: Added footnotes 13 and 16 for the 324 package limitations.</p> <p>¹³ These signals are not available on the 324 package.</p> <p>¹⁶ These signals are available on the Vertical assembly only.</p>

Chapter 3

e200z6 Core Complex

3.1 Introduction

The core complex of the device consists of the e200z6 core, an 8 KB unified cache memory, a 32-entry memory management unit (MMU), a Nexus class 3 block, and a bus interface unit (BIU). The e200z6 core is the central processing unit (CPU) in the device. The e200z6 core is part of the family of CPU cores that implement versions built on the Power Architecture™ embedded category.

The host processor core of the device complies with the Power Architecture embedded category, which is 100 percent user mode compatible with the original Power PC™ user instruction set architecture (UISA). However, in the Power Architecture definition, the original floating-point resources (used by a SIMD design supporting single-precision vector and single-precision scalar operations) are provided that share the GPRs defined for integer instructions.

Refer to the *e200z6 PowerPC™ Core Reference Manual* for more information on the e200z6 core.

3.1.1 Block Diagram

[Figure 3-1](#) shows a block diagram of the e200z6 core complex.

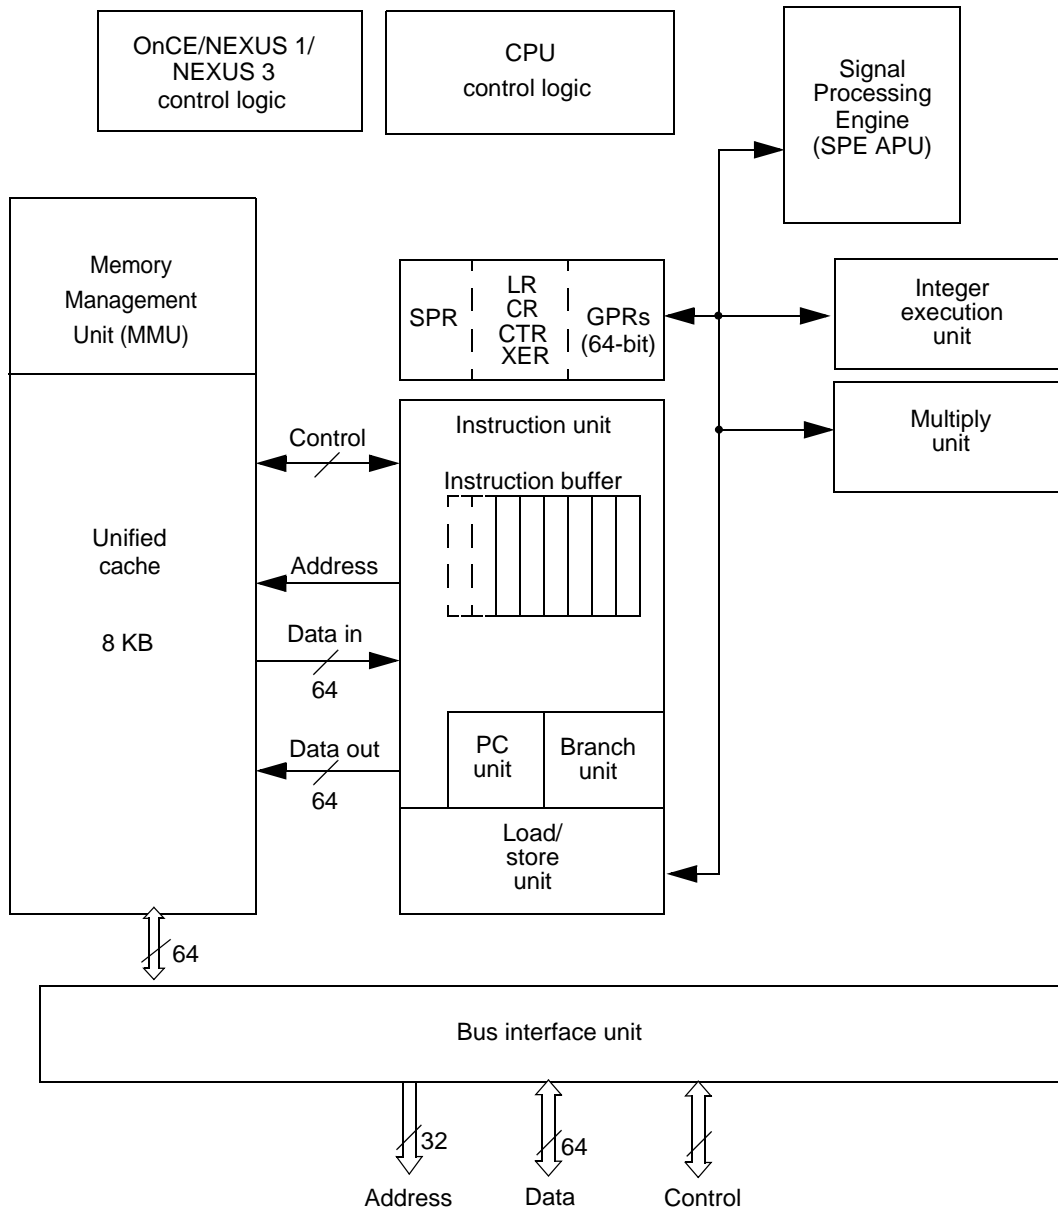

Figure 3-1. e200z6 Block Diagram

3.1.2 Overview

The e200z6 core integrates an integer execution unit, branch control unit, instruction fetch and load/store units, and a multi-ported register file capable of sustaining three read and two write operations per clock. Most integer instructions execute in a single-clock cycle. Branch target prefetching is performed by the branch target address cache to allow single-cycle branches in many cases.

The e200z6 core complex is built on a single-issue, 32-bit Power Architecture design with 64-bit general-purpose registers (GPRs). Power Architecture floating-point instructions are not supported in hardware, but are trapped and may be emulated by software. A signal processing extension (SPE) auxiliary

processing unit (APU) is provided to support real-time fixed point and single-precision floating point operations using the general-purpose registers. All arithmetic instructions that execute in the core operate on data in the GPRs. The registers have been extended to 64-bits to support vector instructions defined by the SPE APU. These instructions operate on 16-bit or 32-bit data types, and produce vector or scalar results.

In addition to the base Power Architecture instruction set, the e200z6 core also implements the VLE (Variable Length Encoding) APU, providing improved code density.

3.1.3 Features

The following is a list of some key features of the e200z6:

- Single issue, 32-bit CPU built on the Power Architecture embedded category
- Implements the VLE APU for reduced code footprint. Refer to *EREF: A Programmer's Reference Manual for Freescale Book E Processors* and to *VLEPIM: Variable Length Encoding (VLE) Extension Programming Interface Manual*.
- In-order execution and retirement
- Precise exception handling
- Branch target address cache
 - Dedicated branch address calculation adder
 - Branch target prefetching
 - Branch lookahead buffers of depth 2
- Load/store unit
 - Pipelined operation supports throughput of one load or store operation per cycle
- 64-bit general-purpose register file
- Memory management unit (MMU) with 32-entry fully-associative TLB and multiple page size support
- Eight KB, two-way set associative unified cache
- Periodic timer and watchdog functions
- Periodic system integrity can be monitored through parallel signature checks
- Signal processing extension APU supporting fixed-point and single-precision floating-point operations, using the 64-bit general-purpose register file
- Nexus class 3 real-time development unit
- Power management
 - Low-power design
 - Dynamic power management of execution units, caches, and MMUs

3.1.3.1 Instruction Unit Features

The features of the instruction unit are the following:

- 64-bit path to cache supports fetching of two 32-bit instructions per clock, or up to four 16-bit VLE APU instructions per clock
- Instruction buffer holds up to six sequential instructions
- Dedicated PC incrementer supporting instruction prefetches
- Branch target address cache with dedicated branch address adder, and branch lookahead logic supporting single cycle execution of successful lookahead branches

3.1.3.2 Integer Unit Features

The integer unit supports single-cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for count leading zeros function
- 32-bit single cycle barrel shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divides in 6–16 clocks with minimized execution timing
- Pipelined 32x32 hardware multiplier array supports 32x32->32 multiply with three clock latency, one clock throughput

3.1.3.3 Load/Store Unit Features

The load/store unit supports load, store, and the load multiple/store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Pipelined operation supports throughput of one load or store operation per cycle
- Dedicated 64-bit interface to memory supports saving and restoring of up to two registers per cycle for load multiple and store multiple word instructions

3.1.3.4 MMU Features

The features of the MMU are as follows:

- Virtual memory support
- 32-bit virtual and physical addresses
- Eight-bit process identifier
- 32-entry fully associative TLB
- Support for nine page sizes (4, 16, 64, and 256 KB; 1, 4, 16, 64, and 256 MB)
- Entry flush protection

3.1.3.5 L1 Cache Features

The features of the cache are as follows:

- Eight KB, two-way set associative unified cache
- Copyback and writethrough support
- Eight-entry store buffer
- Push buffer
- Linefill buffer
- 32-bit address bus plus attributes and control
- Separate unidirectional 64-bit read data bus and 64-bit write data bus
- Supports cache line locking
- Supports way allocation
- Cache power usage can be minimized

3.1.3.6 BIU Features

The features of the e200z6 BIU are as follows:

- 32-bit address bus plus attributes and control
- Separate unidirectional 64-bit read data bus and 64-bit write data bus
- Overlapped, in-order accesses

3.1.4 Microarchitecture Summary

The e200z6 processor utilizes a seven stage pipeline for instruction execution. The instruction fetch 1, instruction fetch 2, instruction decode/register file read, execute1, execute2/memory access1, execute3/memory access2, and register writeback stages operate in an overlapped fashion, allowing single clock instruction execution for most instructions.

The integer execution unit consists of a 32-bit arithmetic unit (AU), a logic unit (LU), a 32-bit barrel shifter (shifter), a mask-insertion unit (MIU), a condition register manipulation unit (CRU), a count-leading-zeros unit (CLZ), a 32 x 32 hardware multiplier array, result feed-forward hardware, and support hardware for division.

Most arithmetic and logical operations are executed in a single cycle with the exception of multiply, which is implemented with a pipelined hardware array, and the divide instructions. A count-leading-zeros unit operates in a single clock cycle.

The instruction unit contains a PC incrementer and a dedicated branch address adder to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer capable of holding six sequential instructions.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in execution time of three clocks. Conditional branches which are not taken execute in a single clock. Branches with successful lookahead and target prefetching have an effective execution time of one clock.

Memory load and store operations are provided for byte, halfword, word (32-bit), and doubleword data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal of data. These instructions can be pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The condition register unit supports the condition register (CR) and condition register operations defined by the Power Architecture embedded category. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Vectored and auto-vectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

The SPE APU supports vector instructions operating on 16- and 32-bit fixed-point data types, as well as 32-bit IEEE-754 single-precision floating-point formats, and supports single-precision floating-point operations in a pipelined fashion. The 64-bit general-purpose register file is used for source and destination operands, and there is a unified storage model for single-precision floating-point data types of 32-bits and the normal integer type. Low latency fixed-point and floating-point add, subtract, multiply, divide, compare, and conversion operations are provided, and most operations can be pipelined.

3.2 Core Registers and Programmer's Model

This section describes the registers implemented in the e200z6 core. It includes an overview of registers defined by the Power Architecture embedded category, highlighting differences in how these registers are implemented in the e200z6 core, and provides a detailed description of core-specific registers. Full descriptions of the architecture-defined register set are provided in the Power Architecture embedded category.

The Power Architecture embedded category defines register-to-register operations for all computational instructions. Source data for these instructions are accessed from the on-chip registers or are provided as immediate values embedded in the opcode. The three-register instruction format allows specification of a target register distinct from the two source registers, thus preserving the original data for use by other instructions. Data is transferred between memory and registers with explicit load and store instructions only.

e200z6 extends the general-purpose registers to 64-bits for supporting SPE APU operations. Power Architecture instructions operate on the lower 32 bits of the GPRs only, and the upper 32 bits are unaffected by these instructions. SPE vector instructions operate on the entire 64-bit register. The SPE APU defines load and store instructions for transferring 64-bit values to/from memory.

[Figure 3-2](#) and [Figure 3-3](#) show the complete e200z6 register set. [Figure 3-2](#) shows the registers that are accessible while in supervisor mode, and [Figure 3-3](#) shows the set of registers that are accessible while in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

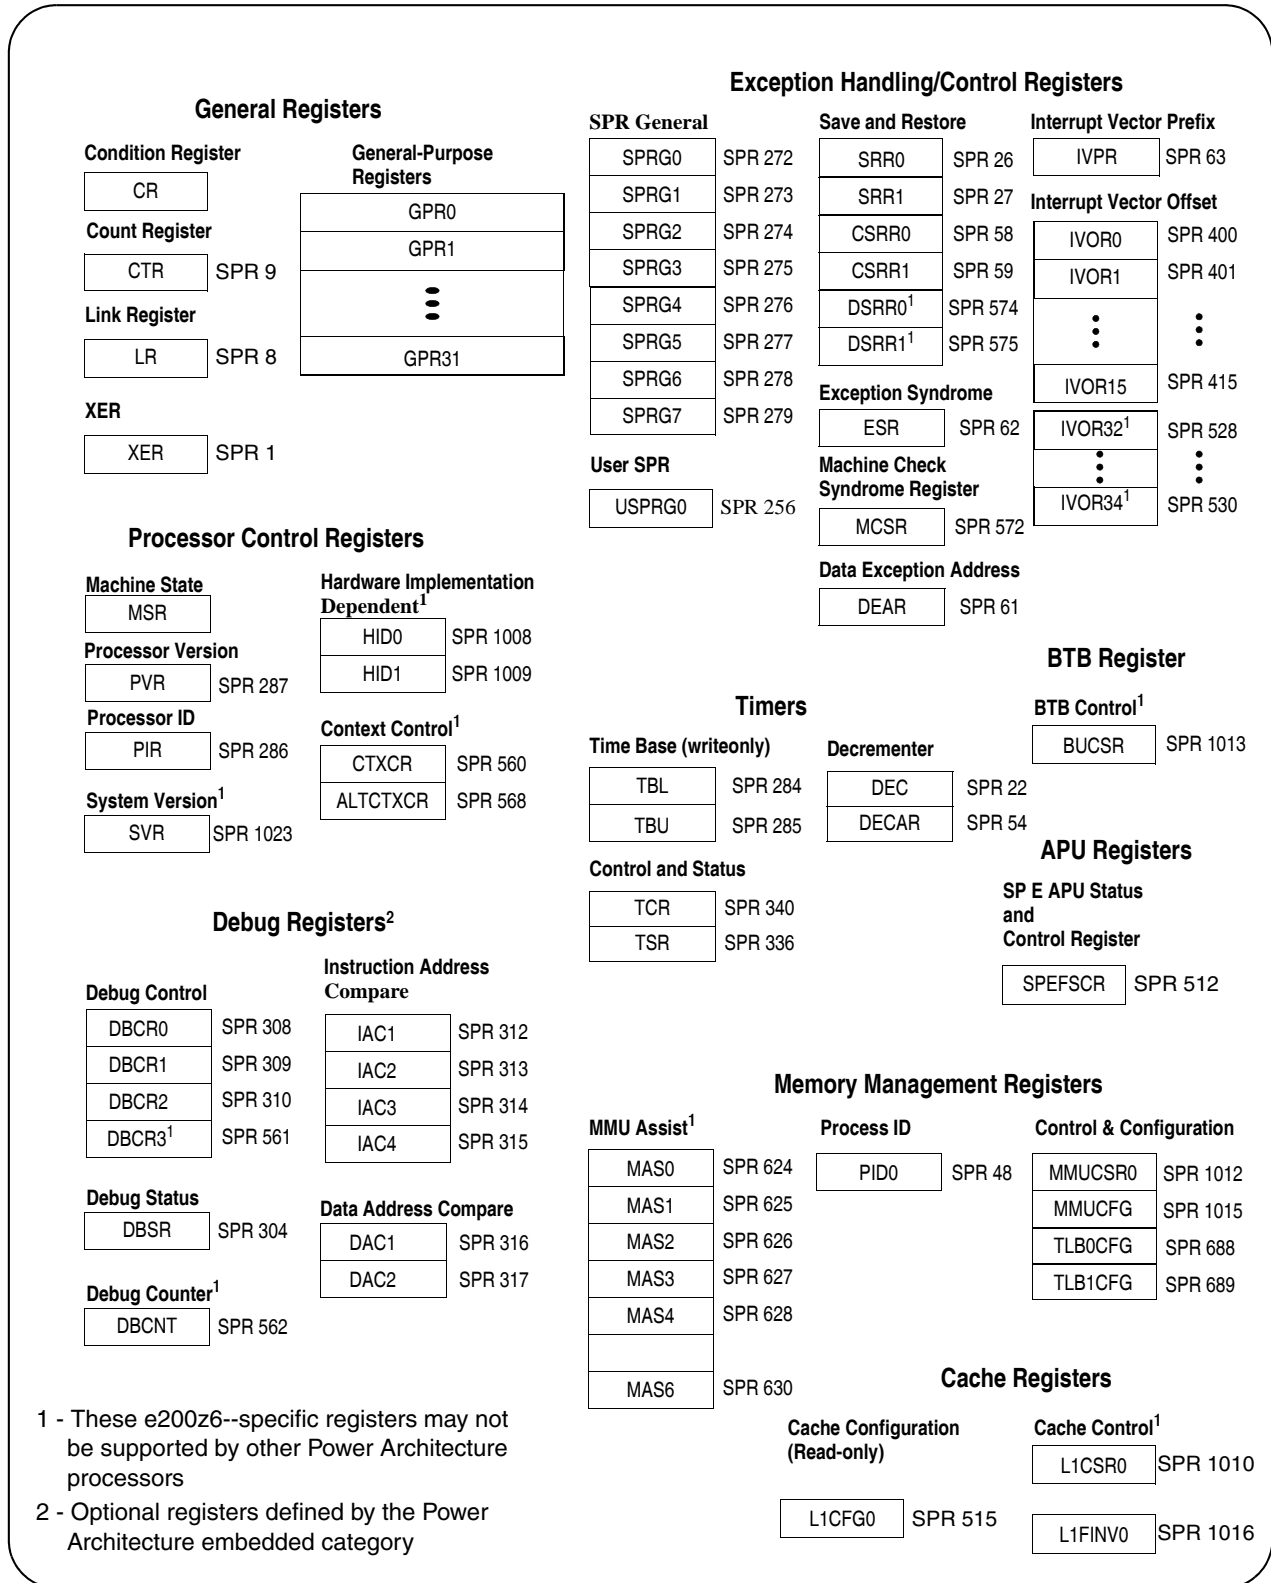

Figure 3-2. Supervisor Mode Programmer's Model

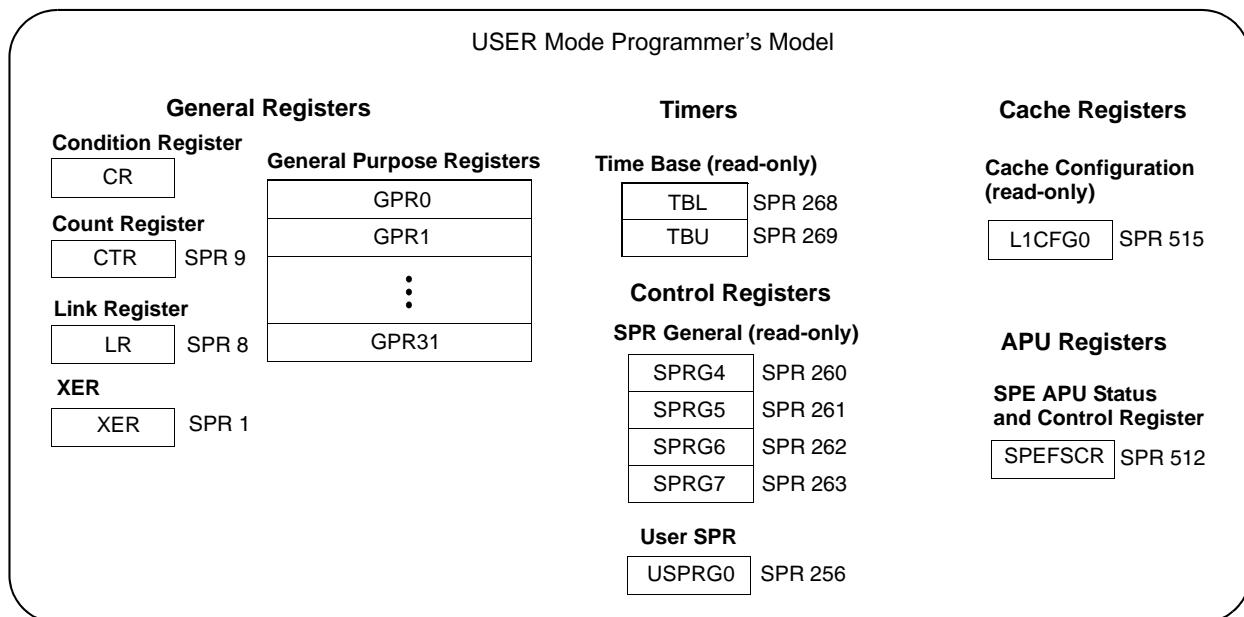

Figure 3-3. User Mode Programmer's Model

3.2.1 Power Architecture Registers

The e200z6 core supports most of the registers defined by the Power Architecture embedded category. Notable exceptions are the floating point registers FPR0–FPR31 and FPSCR. The e200z6 does not support the Power Architecture floating point architecture in hardware. The supported Power Architecture embedded category registers are described as follows:

3.2.1.1 User-Level Registers

The user-level registers can be accessed by all software with user or supervisor privileges. They include the following:

- General-purpose registers (GPRs). The thirty-two 64-bit GPRs (GPR0–GPR31) serve as data source or destination registers for integer and SPE APU instructions and provide data for generating addresses. PowerPC Book E instructions affect only the lower 32 bits of the GPRs. SPE APU instructions are provided which operate on the entire 64-bit register.
- Condition register (CR). The 32-bit CR consists of eight 4-bit fields, CR0–CR7, that reflect results of certain arithmetic operations and provide a mechanism for testing and branching. The remaining user-level registers are SPRs. Note that the PowerPC architecture provides the **mtspr** and **mfspr** instructions for accessing SPRs.
- Integer exception register (XER). The XER indicates overflow and carries for integer operations.
- Link register (LR). The LR provides the branch target address for the branch conditional to link register (**bclr**, **bclrl**) instructions, and is used to hold the address of the instruction that follows a branch and link instruction, typically used for linking to subroutines.

- Count register (CTR). The CTR holds a loop count that can be decremented during execution of appropriately coded branch instructions. The CTR also provides the branch target address for the branch conditional to count register (**bcctr**, **bcctrl**) instructions.
- The time-base facility (TB) consists of two 32-bit registers: time-base upper (TBU) and time-base lower (TBL). These two registers are accessible in a read-only fashion to user-level software.
- SPRG–SPRG7. The PowerPC Book E architecture defines software-use special purpose registers (SPRGs). SPRG4–SPRG7 are accessible as read-only by user-level software. The e200z6 does not allow user mode access to the SPRG3 register (defined as implementation dependent by Book E).
- USPRG0. The PowerPC Book E architecture defines user software-use special purpose register USPRG0 which is accessible in a read-write fashion by user-level software.

3.2.1.2 Supervisor-Level Only Registers

In addition to the registers accessible in user mode, supervisor-level software has access to additional control and status registers an operating system used for configuration, exception handling, and other operating system functions. The Power Architecture embedded category defines the following supervisor-level registers:

- Processor control registers
 - Machine state register (MSR). The MSR defines the state of the processor. The MSR can be modified by the move to machine state register (**mtmsr**), system call (**sc**), and return from exception (**rfi**, **rfdi**, **rfdi**) instructions. It can be read by the move from machine state register (**mfmsr**) instruction. When an interrupt occurs, the contents of the MSR are saved to one of the machine state save/restore registers (SRR1, CSRR1, DSRR1).
 - Processor version register (PVR). This register is a read-only register that identifies the version (model) and revision level of the processor built on the Power Architecture.
 - Processor identification register (PIR). This read-only register is provided to distinguish the processor from other processors in the system.
- Storage control register
 - Process ID register (PID, also referred to as PID0). This register is provided to indicate the current process or task identifier. It is used by the MMU as an extension to the effective address, and by external Nexus 2/3/4 modules for ownership trace message generation. The Power Architecture embedded category allows for multiple PIDs; e200z6 implements only one.
- Interrupt registers
 - Data exception address register (DEAR). After a data storage interrupt (DSI), alignment interrupt, or data TLB miss interrupt, the DEAR is set to the effective address (EA) generated by the faulting instruction.
 - Software-use special purpose registers (SPRGs). The SPRG0–SPRG7 registers are provided for operating system use.
 - Exception syndrome register (ESR). The ESR register provides a syndrome to differentiate between the different kinds of exceptions which can generate the same interrupt.

- Interrupt vector prefix register (IVPR) and the interrupt vector offset registers (IVOR1–IVOR15). These registers together provide the address of the interrupt handler for different classes of interrupts.
- Save/restore registers (SRR0, SRR1). SRR0 holds the effective address for the instruction at which execution resumes when an **rfi** instruction is executed at the end of a non-critical class interrupt handler routine. SRR1 is used to save machine state on a non-critical interrupt, and stores the MSR register contents. The MSR value is restored when an **rfi** instruction is executed at the end of a non-critical class interrupt handler routine.
- Critical save/restore registers (CSRR0, CSRR1). CSRR0 holds the effective address for the instruction at which execution resumes when an **rftci** instruction is executed at the end of a critical class interrupt handler routine. CSRR1 is used to save machine state on a critical interrupt, and stores the MSR register contents. The MSR value is restored when an **rftci** instruction is executed at the end of a critical class interrupt routine.
- Debug facility registers
 - Debug control registers (DBCR0–DBCR2). These registers provide control for enabling and configuring debug events.
 - Debug status register (DBSR). This register contains debug event status.
 - Instruction address compare registers (IAC1–IAC4). These registers contain addresses and/or masks which are used to specify instruction address compare debug events.
 - Data address compare registers (DAC1, DAC2). These registers contain addresses and/or masks which are used to specify data address compare debug events.
 - e200z6 does not implement the data value compare registers (DVC1, DVC2).
- Timer registers
 - The clock inputs for the timers are connected to the internal system clock.
 - Time base (TB). The TB is a 64-bit structure provided for maintaining the time of day and operating interval timers. The TB consists of two 32-bit registers, time-base upper (TBU) and time-base lower (TBL). The time-base registers can be written to by supervisor-level software only, but can be read by both user and supervisor-level software.
 - Decrementer register (DEC). This register is a 32-bit decrementing counter that provides a mechanism for causing a decrementer exception after a programmable delay.
 - Decrementer auto-reload (DECAR). This register is provided to support the auto-reload feature of the decrementer.
 - Timer control register (TCR). This register controls decrementer, fixed-interval timer, and watchdog timer options.
 - Timer status register (TSR). This register contains status on timer events and the most recent watchdog timer-initiated processor reset.

For more details about these registers, refer to the Power Architecture embedded category specifications.

3.2.2 Core-Specific Registers

The Power Architecture embedded category allows implementation-specific registers. Implementation-specific registers incorporated in the e200z6 core are described in this section.

3.2.2.1 User-Level Registers

The user-level registers can be accessed by all software with either user or supervisor privileges. They include the following:

- Signal processing extension APU status and control register (SPEFSCR). The SPEFSCR contains all fixed-point and floating-point exception signal bits, exception summary bits, exception enable bits, and rounding control bits needed for compliance with the IEEE 754 standard.
- The L1 cache configuration register (L1CFG0). This read-only register allows software to query the configuration of the L1 unified cache.

3.2.2.2 Supervisor-Level Registers

The following supervisor-level registers are defined in the e200z6 core in addition to the Power Architecture embedded category registers described previously:

- Configuration registers
 - Hardware implementation-dependent 0 (HID0) controls processor and system functions.
 - Hardware implementation-dependent 1 (HID1) controls processor and system functions.
- Exception handling and control registers
 - Debug save and restore registers (DSRR0, DSRR1). DSRR0 holds the effective address for the instruction at which execution resumes when an **rfdi** instruction is executed at the end of a debug interrupt handler routine. DSRR1 is used to save machine state on a debug interrupt, and stores the MSR register contents. The MSR value is restored when an **rfdi** instruction is executed at the end of a debug interrupt handler routine.
 - When enabled, the DSRR0 register is used to save the address of the instruction at which execution continues when **rfdi** executes at the end of a debug interrupt handler routine.
 - Interrupt vector offset registers (IVOR32–IVOR34). These registers provide the address of the interrupt handler for different classes of interrupts.
- Debug facility registers
 - Debug control register 3 (DBCR3) controls for debug functions not described in the Power Architecture embedded category.
 - Debug counter register (DBCNT) provides counter capability for debug functions.
- Cache registers
 - L1 cache configuration register (L1CFG0) is a read-only register that allows software to query the configuration of the L1 cache.
 - L1 cache control and status register (L1CSR0) controls the operation of the L1 unified cache such as cache enabling, cache invalidation, cache locking, etc.

- L1 cache flush and invalidate register (L1FINV0) controls software flushing and invalidation of the L1 unified cache.
- Memory management unit registers
 - MMU configuration register (MMUCFG) is a read-only register that allows software to query the configuration of the MMU.
 - MMU assist (MAS0-MAS4, MAS6) registers provide the interface to the core from the memory management unit.
 - MMU control and status register (MMUCSR0) controls invalidation of the MMU.
 - TLB configuration registers (TLBCFG0, TLBCFG1) are read-only registers that allow software to query the configuration of the TLBs.
- System version register (SVR) is a read-only and identifies the version (model) and revision level of the system with an e200z6 processor built on the Power Architecture embedded category.

For more details about these registers, refer to the e200z6 core reference documentation.

3.2.3 e200z6 Core Complex Features Not Supported in the Device

The device implements a subset of the e200z6 core complex features. The e200z6 core complex features that are *not* supported in the device are described in [Table 3-1](#).

Table 3-1. e200z6 Features Not Supported in the Device Core

Function / Category	Description
Disabled events	The external debug event (DEVT2) and unconditional debug event (UDE) are not supported.
Power management	e200z6 core halted state and stopped state are not supported.
Power management	The following low-power modes are not supported: Doze mode Nap mode Sleep mode Time-base interrupt wake-up from low-power mode is not supported.
Power management	Core wake up is not supported. MSR[WE] bit in the machine state register is not supported. The OCR[WKUP] bit in the e200z6 OnCE control register (OCR) has no effect.
Machine check	The machine check input pin is not supported. HID0 [EMCP] has no effect, and MCSR[MCP] always reads a negated value.
PVR value	Least significant halfword of processor version register (PVR) is 0x 0000, that contains the following bitfields: MBG Use = 0x00 MBG Rev = 0x0 MBG ID = 0x0 The PVR register has two bitfields in the device.
Reservation management	Reservation management logic external to the e200z6 is not implemented.
Verification	The system version register (SVR) of the e200z6 is 0x 0000_0000.
Time base	The decrement counters are always enabled in the e200z6.

Table 3-1. e200z6 Features Not Supported in the Device Core (continued)

Function / Category	Description
Time Base	The timer external clock is not connected to a clock; Do not select the timer external clock.
Context control	The CTXCR and ALTCXTCR registers are not supported.

3.3 Functional Description

The following sections describe the functions of the e200z6 core blocks.

3.3.1 Memory Management Unit (MMU)

The memory management unit (MMU) is an implementation built on the Power Architecture embedded category with a 32-entry fully associative translation lookaside buffer (TLB). The Power Architecture embedded category divides the effective and real address space into pages. The page represents the granularity of effective address translation, permission control, and memory/cache attributes. The e200z6 MMU supports the following nine page sizes: (4, 16, 64, and 256 KB, 1, 4, 16, 64, and 256 MB).

3.3.1.1 Translation Lookaside Buffer (TLB)

The TLB consists of a 32-entry, fully associative content addressable memory (CAM) array. To perform a lookup, the CAM is searched in parallel for a matching TLB entry. The contents of this TLB entry are then concatenated with the page offset of the original effective address. The result constitutes the physical address of the access. [Table 3-2](#) shows the TLB entry bit definitions.

Table 3-2. TLB Entry Bit Definitions

Field	Comments
V	Valid bit for entry
TS	Translation address space (compared against AS bit)
TID[0:7]	Translation ID (compared against PID0 or '0')
EPN[0:19]	Effective page number (compared against effective address)
RPN[0:19]	Real page number (translated address)
SIZE[0:3]	Page size = 4 KB, 16 KB, 64 KB, 256 KB, 1 MB, 4 MB, 16 MB, 64 MB, 256 MB
SX, SW, SR	Supervisor execute, write, and read permission bits
UX, UW, UR	User execute, write, and read permission bits
WIMGE	Translation attributes (Write-through required, cache-inhibited, memory coherence required, guarded, endian)
U0–U3	User bits—used by software only
IPROT	Invalidation protect
VLE	VLE page indicator

The TLB is accessed indirectly through several MMU assist (MAS) registers. Software can read and write to the MMU assist registers with **mtspr** (move to SPR) and **mfspr** (move from SPR) instructions. The

MMU registers contain information related to reading and writing an entry in the TLB. Data is read from the TLB into the MAS registers with a **tlbre** (TLB read entry) instruction. Data is written to the TLB from the MAS registers with a **tlbwe** (TLB write entry) instruction.

Refer to [Section 3.3.1.5, “MMU Assist Registers \(MAS\[0:4\], MAS\[6\]\),”](#) and the *e200z6 PowerPC™ Core Reference Manual* for more details.

3.3.1.2 Translation Flow

The effective address, concatenated with the address space value of the MSR bit (MSR[IS] or MSR[DS]), is compared to the number of bits of the EPN field and the TS field of TLB entries. If the contents of the effective address plus the address space bit matches the EPN field and TS bit of the TLB entry, that TLB entry is a candidate for a possible translation match. In addition to a match in the EPN field and TS, a matching TLB entry must match with the current process ID of the access (in PID0), or have a TID value of 0, indicating the entry is globally shared among all processes.

[Figure 3-4](#) shows the translation match logic for the effective address plus its attributes, collectively called the virtual address, and how it is compared with the corresponding fields in the TLB entries.

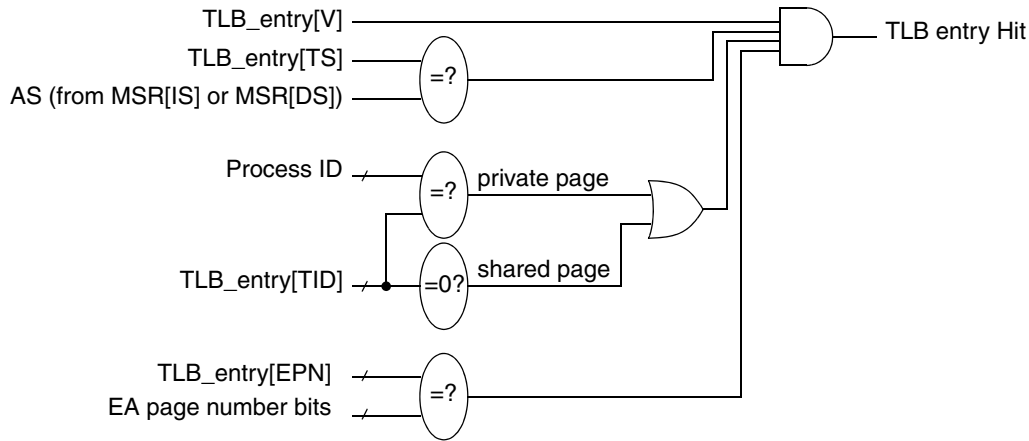

Figure 3-4. Virtual Address and TLB-Entry Compare Process

3.3.1.3 Effective to Real Address Translation

Instruction accesses are generated by sequential instruction fetches or due to a change in program flow (branches and interrupts). Data accesses are generated by load, store, and cache management instructions. The instruction fetch, branch, and load/store units generate 32-bit effective addresses. The MMU translates this effective address to a 32-bit real address which is then used for memory accesses. [Figure 3-5](#) shows the effective to real address translation flow.

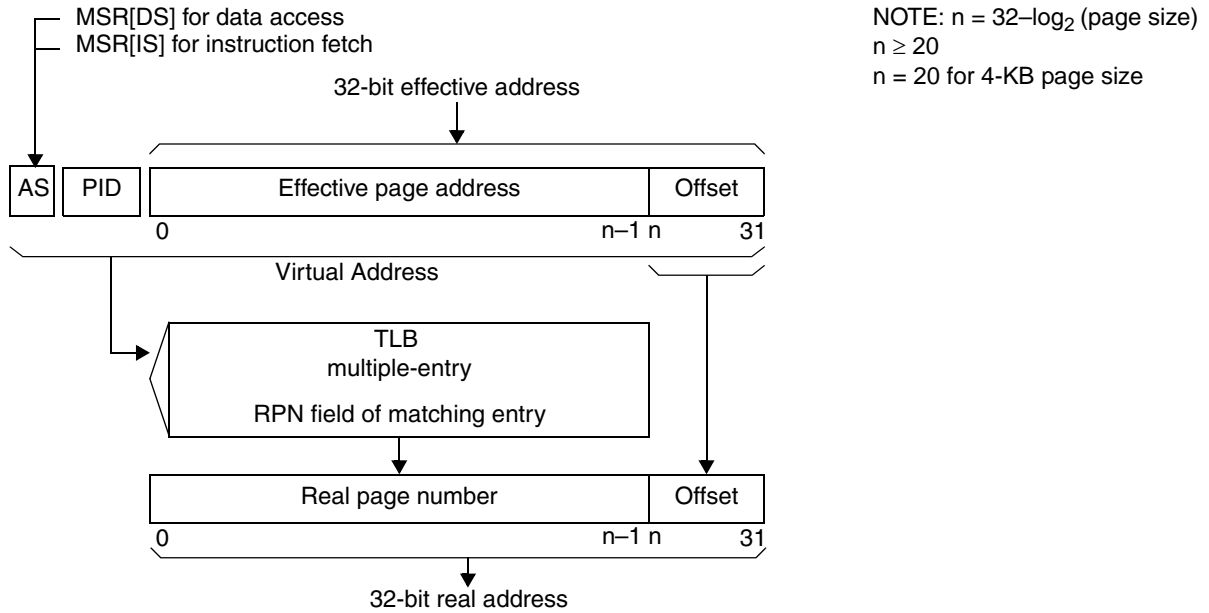

Figure 3-5. Effective to Real Address Translation Flow

3.3.1.4 Permissions

The application software can restrict access to virtual pages by selectively granting permissions for user mode read, write, and execute, and supervisor mode read, write, and execute on a per-page basis. For example, program code might be execute-only and data structures can be mapped as read/write/no-execute.

The UX, SX, UW, SW, UR, and SR access control bits support selective permissions for access control:

- SR—Supervisor read permission. Allows loads and load-type cache management instructions to access the page while in supervisor mode.
- SW—Supervisor write permission. Allows stores and store-type cache management instructions to access the page while in supervisor mode.
- SX—Supervisor execute permission. Allows instruction fetches to access the page and instructions to be executed from the page while in supervisor mode.
- UR—User read permission. Allows loads and load-type cache management instructions to access the page while in user mode.
- UW—User write permission. Allows stores and store-type cache management instructions to access the page while in user mode.
- UX—User execute permission. Allows instruction fetches to access the page and instructions to be executed from the page while in user mode.

If the translation match was successful, the permission bits are checked as shown in Figure 3-6. If the access is not allowed by the access permission mechanism, the processor generates an instruction or data storage interrupt (ISI or DSI).

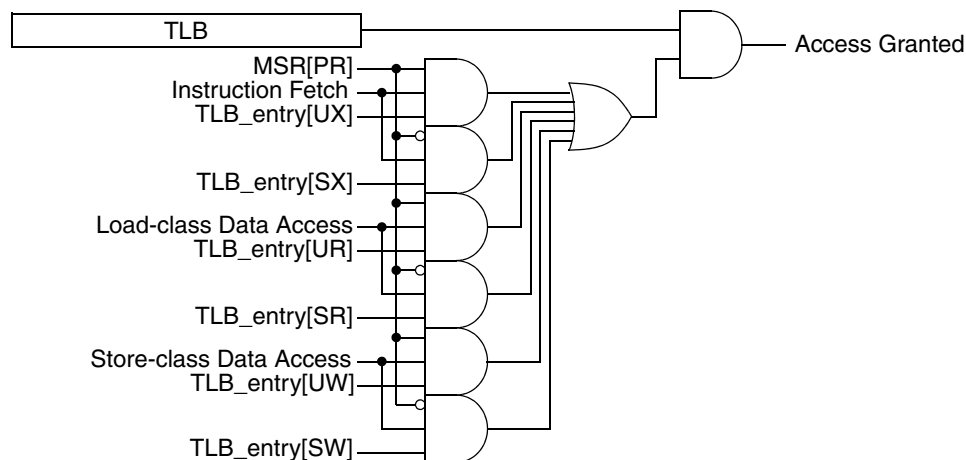

Figure 3-6. Granting of Access Permission

3.3.1.5 MMU Assist Registers (MAS[0:4], MAS[6])

The e200z6 uses six special purpose registers (MAS[0], MAS[1], MAS[2], MAS[3], MAS[4], and MAS[6]) to facilitate reading, writing, and searching the TLBs. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions. The e200z6 does not implement the MAS5 register, present in other Freescale EIS designs, because the **tlbsx** instruction only searches based on a single SPID value.

For more information on the MAS_n registers is available in the *e200z6 PowerPC™ Core Reference Manual*.

3.3.1.5.1 MAS[0] Register

The MAS[0] register is shown in [Figure 3-7](#).

Figure 3-7. MAS Register 0 Format — MAS[0]

MAS[0] fields are defined in [Table 3-3](#).

Table 3-3. MAS[0] — MMU Read/Write and Replacement Control

Field	Description
0–1	Reserved, must be cleared.
2–3 TLBSEL	Selects TLB for access. 01 TLB1 (ignored by the e200z6, write to 01 for future compatibility)
4–10	Reserved, must be cleared.
11–15 ESEL	Entry select for TLB1.
16–26	Reserved, must be cleared.
27–31 NV	Next replacement victim for TLB1 (software managed). Software updates this field; it is copied to the ESEL field on a TLB error.

3.3.1.5.2 MAS[1] Register

The MAS[1] register is shown in [Figure 3-8](#).

Figure 3-8. MMU Assist Register 1 — MAS[1]

MAS[1] fields are defined in [Table 3-4](#).

Table 3-4. MAS[1] — Descriptor Context and Configuration Control

Field	Description
0 VALID	TLB entry valid. 0 This TLB entry is invalid. 1 This TLB entry is valid.
1 IPROT	Invalidation protect 0 Entry is not protected from invalidation. 1 Entry is protected from invalidation. Protects TLB entry from invalidation by tlbivax (TLB1 only), or flash invalidates through MMUCSR0[TLB1_FI].
2–7	Reserved, must be cleared.
8–15 TID	Translation ID bits. This field is compared with the current process IDs of the effective address to be translated. A TID value of 0 defines an entry as global and matches with all process IDs.
16–18	Reserved, must be cleared.
19 TS	Translation address space. This bit is compared with the IS or DS fields of the MSR (depending on the type of access) to determine if this TLB entry can be used for translation.
20–23 TSIZE	Entry page size. Supported page sizes are: 0001 4 KB 0110 4 MB 0010 16 KB 0111 16 MB 0011 64 KB 1000 64 MB 0100 256 KB 1001 256 MB 0101 1 MB All other values are undefined.
24–31	Reserved, must be cleared.

3.3.1.5.3 MAS[2] Register

The MAS[2] register is shown in [Figure 3-9](#).

Figure 3-9. MMU Assist Register 2 — MAS[2]

MAS[2] fields are defined in [Table 3-5](#).

Table 3-5. MAS[2] — EPN and Page Attributes

Field	Description
0–19 EPN	Effective page number [0:19].
20–25	Reserved, must be cleared.
26 VLE	Power Architecture VLE. 0 This page is a standard Book E page. 1 This page is a Power Architecture VLE page.
27 W	Write-through required. 0 This page is considered write-back with respect to the caches in the system. 1 All stores performed to this page are written through to main memory.
28 I	Cache inhibited. 0 This page is considered cacheable. 1 This page is considered cache-inhibited.
29 M	Memory coherence required. The e200z6 does <u>not</u> support the memory coherence required attribute, and thus it is ignored. 0 Memory coherence is not required. 1 Memory coherence is required.
30 G	Guarded. The e200z6 ignores the guarded attribute because no speculative or out-of-order processing is performed. 0 Access to this page are not guarded, and can be performed before it is known if they are required by the sequential execution model. 1 All loads and stores to this page are performed without speculation (that is, they are known to be required).
31 E	Endianness. Determines endianness for the corresponding page. 0 The page is accessed in big-endian byte order. 1 The page is accessed in true little-endian byte order.

3.3.1.5.4 MAS[3] Register

The MAS[3] register is shown in [Figure 3-10](#).

Figure 3-10. MMU Assist Register 3 — MAS[3]

MAS[3] fields are defined in [Table 3-6](#).

Table 3-6. MAS[3] — RPN and Access Control

Field	Description
0–19 RPN	Real page number. Only bits that correspond to a page number are valid. Bits that represent offsets within a page are ignored and must be zero.
20–21	Reserved, must be cleared.
22–25 U0–U3	User bits.
26–31 PERMIS	Permission bits (UX, SX, UW, SW, UR, SR).

3.3.1.5.5 MAS[4] Register

The MAS[4] register is shown in [Figure 3-11](#).

Figure 3-11. MMU Assist Register 4 MAS[4]

MAS[4] fields are defined in [Table 3-7](#).

Table 3-7. MAS[4]—Hardware Replacement Assist Configuration Register

Field	Description
0–1	Reserved, must be cleared.
2–3 TLBSELD	Default TLB selected 01 TLB1 (ignored by the e200z6, write as 01 for future compatibility)
4–13	Reserved, must be cleared.

Table 3-7. MAS[4]—Hardware Replacement Assist Configuration Register (continued)

Field	Description
14–15 TIDSELD	Default PID# to load TID from 00 PID0 01 Reserved, do not use 10 Reserved, do not use 11 TIDZ (0x00) (Use all zeros, the globally shared value)
16–19	Reserved, must be cleared.
20–23 TSIZED	Default TSIZE value
24–25	Reserved, must be cleared.
26 VLED	Default VLED value
27–31 DWIMGE	Default WIMGE values

3.3.1.5.6 MAS[6] Register

The MAS[6] register is shown in [Figure 3-12](#).

Figure 3-12. MMU Assist Register 6 — MAS[6]

MAS[6] fields are defined in [Table 3-8](#).

Table 3-8. MAS[6] — TLB Search Context Register 0

Field	Description
0–7	Reserved, must be cleared.
8–15 SPID	PID value for searches
16–30	Reserved, must be cleared.
31 SAS	AS value for searches

3.3.2 L1 Cache

The e200z6 processor supports a 8-KB, 2-way set-associative, unified (instruction and data) cache with a 32-byte line size. The cache improves system performance by providing low-latency data to the e200z6 instruction and data pipelines, which decouples processor performance from system memory performance. The cache is virtually indexed and physically tagged. The e200z6 does not provide hardware support for cache coherency in a multi-master environment. Software must be used to maintain cache coherency with other possible bus masters.

Both instruction and data accesses are performed using a single bus connected to the cache. Addresses from the processor to the cache are virtual addresses used to index the cache array. The MMU provides the virtual to physical translation for use in performing the cache tag compare. If the physical address matches a valid cache tag entry, the access hits in the cache. For a read operation, the cache supplies the data to the processor, and for a write operation, the data from the processor updates the cache. If the access does not match a valid cache tag entry (misses in the cache) or a write access must be written through to memory, the cache performs a bus cycle on the system bus. Figure 3-13 shows a block diagram of the unified cache in the e200z6.

Figure 3-13. e200z6 Unified Cache Block Diagram

3.3.2.1 Cache Organization

The e200z6 cache is organized as two ways of 128 sets with each line containing 32 bytes (four doublewords) plus parity of storage. Figure 3-14 illustrates the cache organization, terminology used, the cache line format, and cache tag formats.

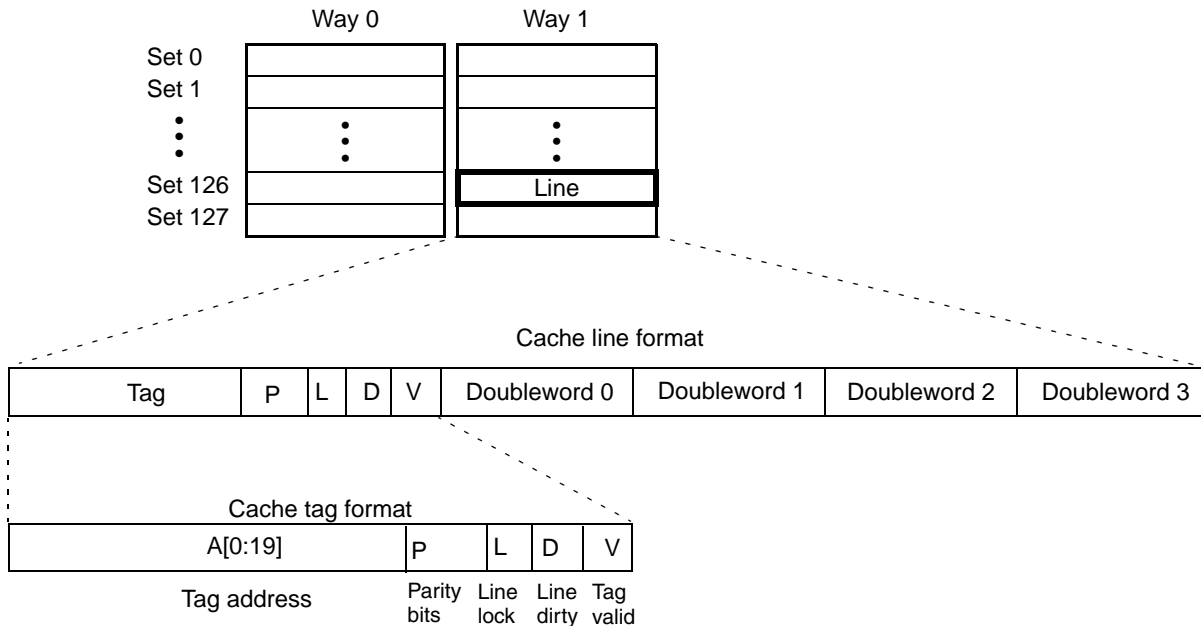

Figure 3-14. Cache Organization and Line Format

3.3.2.2 Cache Lookup

After it is enabled, the unified cache is searched for a tag match on all instruction fetches and data accesses from the CPU. If a match is found, the cached data is forwarded on a read access to the instruction fetch unit or the load/store unit (data access), or is updated on a write access, and can also be written-through to memory if required.

When a read miss occurs, if there is a TLB hit and the cache inhibit bit (WIMGE=0bx0xxx) of the hitting TLB entry is clear, the translated physical address is used to fetch a four doubleword cache line beginning with the requested doubleword (critical doubleword first). The line is fetched and placed into the appropriate cache block and the critical doubleword is forwarded to the CPU. Subsequent doublewords can be streamed to the CPU if they have been requested and streaming is enabled via the DSTRM bit in the L1CSR0 register.

During a cache line fill, doublewords received from the bus are placed into a cache linefill buffer, and can be forwarded (streamed) to the CPU if such a request is pending. Accesses from the CPU following delivery of the critical doubleword can be satisfied from the cache (hit under fill, non-blocking) or from the linefill buffer if the requested information has been already received.

The cache always fills an entire line, thereby providing validity on a line-by-line basis. A cache line is always in one of the following states: invalid, valid, or dirty (and valid). For invalid lines, the V bit is clear, causing the cache line to be ignored during lookups. Valid lines have their V bit set and D bit cleared,

indicating the line contains valid data consistent with memory. Dirty cache lines have the D and V bits set, indicating that the line has valid entries that have not been written to memory. In addition, a cache line can be locked (L bit set) indicating the line is not available for replacement.

The cache must be invalidated after a hardware reset; a hardware reset does not invalidate the cache lines. Following initial power-up, the cache contents are undefined. If the L, D, or V bits are set on any lines, the software must invalidate cache before the cache is enabled.

Figure 3-15 illustrates the general flow of cache operation.

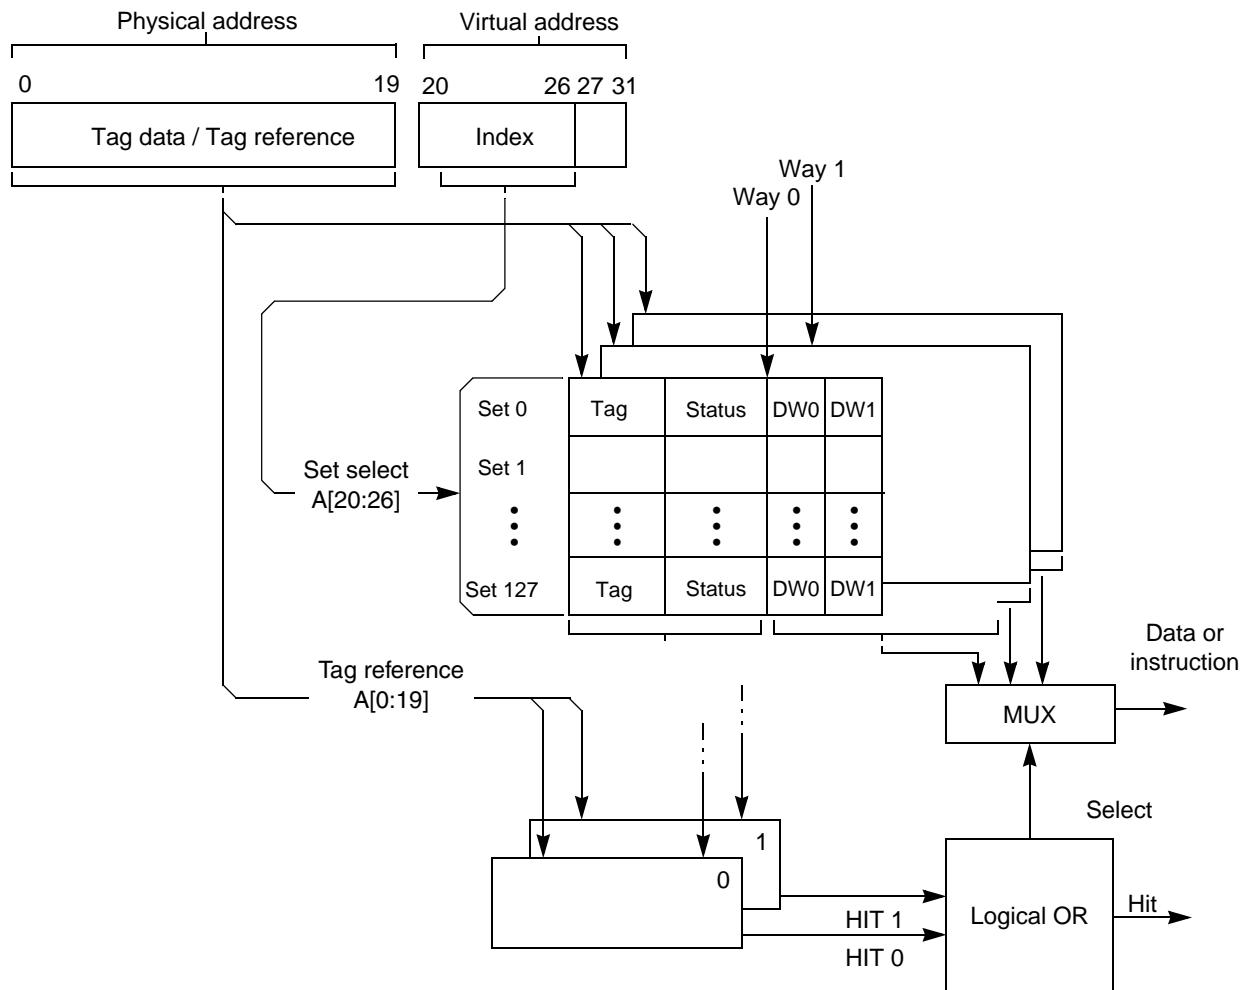

Figure 3-15. Cache Lookup Flow

To determine if the address is already allocated in the cache the following steps are taken:

1. The cache set index, virtual address bits A[20:26] are used to select one cache set. A set is defined as the grouping of two lines (one from each way), corresponding to the same index into the cache array.
2. The higher order physical address bits A[0:19] are used as a tag reference or used to update the cache line tag field.

3. The two tags from the selected cache set are compared with the tag reference. If any one of the tags matches the tag reference and the tag status is valid, a cache hit has occurred.
4. Virtual address bits A[27:28] are used to select one of the four doublewords in each line. A cache hit indicates that the selected doubleword in that cache line contains valid data (for a read access), or can be written with new data depending on the status of the W access control bit from the MMU (for a write access).

3.3.2.3 Cache Line Replacement Algorithm

On a cache read miss, the cache controller uses a pseudo-round-robin replacement algorithm to determine which cache line will be selected to be replaced. There is a single replacement counter for the entire cache. The replacement algorithm acts as follows: on a miss, if the replacement pointer is pointing to a way which is not enabled for replacement by the type of the miss access (the selected line or way is locked), it is incremented until an available way is selected (if any). After a cache line is successfully filled without error, the replacement pointer increments to point to the next cache way.

3.3.2.4 Cache Power Reduction

The device provides additional user control over cache power utilization via the L1CSR0[WID], [AWID], [WDD], and [AWDD] way disable bits and the L1CSR0[WAM] control bit. When WAM is set to 1, ways that are disabled for allocation on miss by a particular access type (instruction or data) via the L1CSR0[WID], [AWID], [WDD], and [AWDD] way disable bits are also disabled (not selected) during normal cache lookup operations, thus avoiding the power associated with reading tag and data information for a disabled way. This provides the capability of disabling some ways for instruction accesses and some ways for data accesses to reduce power. In doing so however, certain restrictions must be followed, and the ability to lock by way is no longer functional, since a locked way would never be accessed.

When setting WAM to 1, restrictions are required to avoid coherency issues between instruction and data accesses, and to avoid multiple ways hitting on a given access. The restriction on coherency is due to the fact that a given line could possibly be present twice in the cache; a copy in a way disabled for instruction access which can be read and written by data accesses, and a second copy in a way disabled for data access which can be executed via an instruction fetch. A data write to the line will result in the possibility of instruction fetches obtaining stale data, in the same manner as exists in a non-unified cache. Another restriction is that multiple hits to the same line must be avoided on any given instruction or data access. This must be avoided by controlling the ways via the L1CSR0[WID,] [WDD], [AWID], and [AWDD] bits such that no common way exists that can be accessed by both instructions and data, or by ensuring that MMU permissions are set so that no cacheable page has X (execute) permission which also has R (read) or W (write) permission, i.e. can be cacheable and accessed with both instruction and data accesses.

When WAM is set to 1, ways disabled for instruction access are not affected by the **icbt**, **icble**, **icbtls**, and **icbi** instructions. Ways disabled for data accesses are not affected by the **dcb**, **dcbf**, **dcbi**, **dcbic**, **dcbst**, **dcbt**, **dcbtls**, **dcbtst**, **dcbtstls**, and **dcbz** instructions. Cache control operations using L1CSR0[CINV] and L1FINV0 operations are not affected by the WAM setting and proceed normally.

3.3.2.5 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 cache control and status register 0 (L1CSR0) is a 32-bit register. The L1CSR0 register is accessed using a **mf spr** or **mt spr** instruction. The SPR number for L1CSR0 is 1010 in decimal. The L1CSR0 register is shown in [Figure 3-16](#).

The correct sequence necessary to change the value of L1CSR0 is as follows:

1. **msync**
2. **isync**
3. **mt spr L1CSR0**

Figure 3-16. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 bits are described in [Table 3-9](#).

Table 3-9. L1CSR0 Field Descriptions

Bits	Name	Description
0:1	WID	Way instruction disable. 0 = The corresponding way is available for replacement by instruction miss line fills. 1 = The corresponding way is not available for replacement by instruction miss line fills. Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID and WDD bits can be used for locking ways of the cache, and also are used in determining the replacement policy of the cache.
2:3	—	Reserved
4:5	WDD	Way data disable. 0 = The corresponding way is available for replacement by data miss line fills. 1 = The corresponding way is not available for replacement by data miss line fills. Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WID and WDD bits can be used for locking ways of the cache, and also are used in determining the replacement policy of the cache.
6:9	—	Reserved

Table 3-9. L1CSR0 Field Descriptions (continued)

Bits	Name	Description
10	WAM	<p>Way access mode</p> <p>0 = Disable way access is checked not enabled for replacement on an access type are still checked for a cache hit for accesses of that type but are not replaced by an access miss of that type.</p> <p>1 = Ways not enabled for replacement on a particular access type (instruction vs. data) via the WID and WDD fields are disabled and no lookup is performed for accesses of that type. Selecting WAM = 1 helps minimize power consumption.</p> <p>Software <i>must</i> ensure that the instruction to data coherency is maintained when using the power-saving feature of the WAM control. Cache must be invalidated prior to changing the value of this bit. Use of a dcbf followed by an icbi, msync, isync for modified lines which can be executed is required to maintain proper operation.</p>
11	CWM	<p>Cache write mode</p> <p>0 = Cache operates in writethrough mode</p> <p>1 = Cache operates in copyback mode</p> <p>When set to writethrough mode, the “W” page attribute from an optional MMU is ignored and all writes are treated as writethrough required. When set, write accesses are performed in copyback mode unless the “W” page attribute from an optional MMU is set.</p>
12	DPB	<p>Disable push buffer</p> <p>0 = Push buffer enabled</p> <p>1 = Push buffer disabled</p>
13	DSB	<p>Disable store buffer</p> <p>0 = store buffer enabled</p> <p>1 = store buffer disabled</p>
14	DSTRM	<p>Disable streaming</p> <p>0 = streaming is enabled</p> <p>1 = streaming is disabled</p>
15	CPE	<p>Cache parity enable</p> <p>0 = parity checking is disabled</p> <p>1 = parity checking is enabled</p>
16–20	—	Reserved
21	CUL	<p>Cache unable to lock</p> <p>Indicates a lock set instruction was not effective in locking a cache line. This bit is set by hardware on an “unable to lock” condition (other than lock overflows), and will remain set until cleared by software writing 0 to this bit location.</p>
22	CLO	<p>Cache lock overflow</p> <p>Indicates a lock overflow (overlocking) condition occurred. This bit is set by hardware on an “overlocking” condition, and will remain set until cleared by software writing 0 to this bit location.</p>

Table 3-9. L1CSR0 Field Descriptions (continued)

Bits	Name	Description
23	CLFC	Cache lock bits flash clear When written to a 1, a cache lock bits flash clear operation is initiated by hardware. After this is complete, this bit is reset to 0. Writing a 1 while a flash clear operation is in progress will result in an undefined operation. Writing a 0 to this bit while a flash clear operation is in progress will be ignored. Cache lock bits flash clear operations require approximately cycles to complete. Clearing occurs regardless of the enable (CE) value.
24:28	—	Reserved
29	CABT	Cache operation aborted Indicates a cache invalidate or a cache lock bits flash clear operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	CINV	Cache invalidate 0 = No cache invalidate 1 = Cache invalidation operation When written to a 1, a cache invalidation operation is initiated by hardware. After this is complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately cycles to complete. Invalidation occurs regardless of the enable (CE) value.
31	CE	Cache Enable 0 = Cache is disabled 1 = Cache is enabled When disabled, cache lookups are not performed for normal load or store accesses. Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by CE.

3.3.2.6 L1 Cache Configuration Register 0 (L1CFG0)

The L1 cache configuration register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the L1 cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The SPR number for L1CFG0 is 515 in decimal. The L1CFG0 register is shown in [Figure 3-17](#).

Figure 3-17. L1 Cache Configuration Register 0 (L1CFG0)

The L1CFG0 bits are described in [Table 3-10](#).

Table 3-10. L1CFG0 Field Descriptions

Bits	Name	Description
0–1	CARCH	Cache architecture 01 - The cache architecture is unified
2	CWPA	Cache way partitioning available 1 - The cache supports partitioning of way availability for I/D accesses
3	CFAHA	Cache flush all by hardware available 0 - The cache does not support flush all in hardware
4	CFISWA	Cache flush/invalidate by set and way available 1 - The cache supports flushing/invalidation by set and way via the L1FINV0 spr
5–6	—	Reserved—read as zeros
7–8	CBSIZE	Cache block size 00 - The cache implements a block size of 32 bytes
9–10	CREPL	Cache replacement policy 10 - The cache implements a pseudo-round-robin replacement policy
11	CLA	Cache locking APU available 1 - The cache implements the line locking APU
12	CPA	Cache parity available 1 - The cache implements parity
13:20	CNWAY	Number of ways in the data cache 0x01 - The cache is 2-way set-associative
21:31	CSIZE	Cache size 0x008 - The size of the cache is 8 KB

3.3.3 Interrupt Types

The interrupts implemented in the device and the exception conditions that cause them are listed in [Table 3-11](#).

Table 3-11. Interrupts and Conditions

Interrupt Type	Interrupt Vector Offset Register	Enables ¹	Core Register in Which State Information is Saved	Causing Conditions
System reset	none, vector to 0xFFFF_FFFC			<ul style="list-style-type: none"> Reset by assertion of $\overline{\text{RESET}}$ Watchdog timer reset control Debug reset control
Critical input	IVOR0	IVOR0 is not supported in the device		

Table 3-11. Interrupts and Conditions (continued)

Interrupt Type	Interrupt Vector Offset Register	Enables ¹	Core Register in Which State Information is Saved	Causing Conditions
Machine check	IVOR 1	ME	CSSR[0:1]	<ul style="list-style-type: none"> Machine check exception and MSR[ME] =1 ISI, ITLB error on first instruction fetch for an exception handler Parity error signaled on cache access Write bus error on buffered store or cache line push
Data storage	IVOR 2	—	SRR[0:1]	<ul style="list-style-type: none"> Access control Byte ordering due to misaligned access across page boundary to pages with mismatched E bits Cache locking exception Precise external termination error
Instruction storage	IVOR 3	—	SRR[0:1]	<ul style="list-style-type: none"> Access control. Precise external termination error.
External input	IVOR 4 ²	EE, src	SRR[0:1]	External interrupt is asserted and MSR[EE]=1
Alignment	IVOR 5	—	SRR[0:1]	<ul style="list-style-type: none"> lmw, stmw not word aligned lwarx or stwcx. not word aligned dcbz with disabled cache or no cache present, or to W or I storage SPE ld and st instructions not properly aligned
Program	IVOR 6	—	SRR[0:1]	Illegal, privileged, trap, FP enabled, AP enabled, unimplemented operation
Floating-point unavailable	IVOR 7	—	SRR[0:1]	MSR[FP]=0 and attempt to execute a Book E floating point operation
System call	IVOR 8	—	SRR[0:1]	Execution of the system call (sc) instruction
AP unavailable	IVOR 9	—	SRR[0:1]	Unused by e200z6
Decrementer	IVOR 10	EE, DIE	SRR[0:1]	Decrementer timeout, and as specified in <i>Book E: Enhanced PowerPC™ Architecture, Rev 1.0</i> , Ch. 8, pg. 194–195 and in the <i>e200Z6 PowerPC™ Core Reference Manual, Rev 0</i> .
Fixed interval timer	IVOR 11	EE, FIE	SRR[0:1]	Fixed-interval timer timeout and as specified in <i>Book E: Enhanced PowerPC™ Architecture, Rev 1.0</i> , Ch. 8, pg. 195–196 and in the <i>e200Z6 PowerPC™ Core Reference Manual, Rev 0</i> .
Watchdog timer	IVOR 12	CE, WIE	CSRR[0:1]	Watchdog timeout: as specified in <i>Book E: Enhanced PowerPC™ Architecture, Rev 1.0</i> , Ch. 8, pg. 196–197 and in the <i>e200Z6 PowerPC™ Core Reference Manual, Rev 0</i> .
Data TLB error	IVOR 13	—	SRR[0:1]	Data translation lookup did not match a valid entry in the TLB
Instruction TLB error	IVOR 14	—	SRR[0:1]	Instruction translation lookup did not match a valid TLB entry

Table 3-11. Interrupts and Conditions (continued)

Interrupt Type	Interrupt Vector Offset Register	Enables ¹	Core Register in Which State Information is Saved	Causing Conditions
Debug	IVOR 15	DE, IDM	CSSR[0:1]	Debugger when HIDO[DAPUEN] = 0. Caused by trap, instruction address compare, data address compare, instruction complete, branch taken, return from interrupt, interrupt taken, debug counter, external debug event, unconditional debug event
		DE, IDM	DSRR[0:1]	Debugger when HIDO[DAPUEN] = 1, and caused by same conditions as above.
Reserved	IVOR 16–31			
SPE unavailable exception	IVOR 32	—	SRR[0:1]	SPE APU instruction when MSR[SPE] = 0, and see Section 5.6.18 “SPE APU Unavailable Interrupt” in the <i>e200Z6 PowerPC™ Core Reference Manual</i> , Rev 0.
SPE data exception	IVOR 33	—	SRR[0:1]	SPE FP data exception and see Section 5.6.19 “SPE Floating-Point Data Interrupt” in the <i>e200Z6 PowerPC™ Core Reference Manual</i> , Rev 0.
SPE round exception	IVOR 34	—	SRR[0:1]	Inexact result from floating-point instruction. See Section 5.6.20 “SPE Floating-Point Round Interrupt” in the <i>e200Z6 PowerPC™ Core Reference Manual</i> , Rev 0.

¹ CE, ME, EE, DE are in the MSR. DIE, FIE, and WIE are in the TCR. “src” signifies the individual enable for each INTC source. The debug interrupt, IVOR 15, also requires EDM = 0 (EDM and IDM are in the DBCR0 register).

3.3.4 Bus Interface Unit (BIU)

The BIU encompasses control and data signals supporting instruction and data transfers. A data bus width of 64-bits is implemented. The memory interface supports read and write transfers of 8, 16, 24, 32, and 64 bits, supports burst transfers of four doublewords, and operates in a pipelined fashion.

Single-beat transfers are supported for cache-inhibited read and write cycles, and write-buffer writes. Burst transfers of four doublewords are supported for cache linefill and copyback operations.

3.3.5 Timer Facilities

The core provides a set of registers to provide fixed interval timing and watchdog functions for the system. All of these must be initialized during start-up. The registers associated with fixed interval timer and watchdog functions are the following:

- Timer control register (TCR)—provides control of the timer and watchdog facilities.
- Timer status register (TSR)—provides status of the timer facilities.
- Time base registers (TBU and TBL)—two 32-bit registers (upper and lower) that are concatenated to provide a long-period, 64-bit counter.

- Decrementer register (DEC)—a decrementing counter that is updated at the same rate as the time base. The DEC provides a means of signaling an exception after a specified amount of time. The DEC is typically used as a general-purpose software timer. Note that the decrementer always runs when the system is clocked, and can be written to by software at any time.
- Decrementer auto reload register (DECAR)—provides a value that is automatically reloaded (if enabled) into the decrementer register when the decrementer reaches 0.

For more information on the fixed-interval timer, watchdog timer, and timer and counter registers, refer to the *e200z6 PowerPC™ Core Reference Manual* and *EREF: A Programmer's Reference Manual for Freescale Book E Processors*.

3.3.6 Signal Processing Extension APU (SPE APU)

3.3.6.1 Overview

The Power Architecture embedded category 32-bit instructions operate on the lower (least significant) 32 bits of the 64-bit GPRs. New SPE instructions are defined that view the 64-bit register as being composed of a vector of two 32-bit elements, and some of the instructions also read or write 16-bit elements. These new instructions can also be used to perform scalar operations by ignoring the results of the upper 32-bit half of the register file.

Some instructions are defined that produce a 64-bit scalar result. Vector fixed-point instructions operate on a vector of two 32-bit or four 16-bit fixed-point numbers resident in the 64-bit GPRs. Vector floating-point instructions operate on a vector of two 32-bit single-precision floating-point numbers resident in the 64-bit GPRs. Scalar floating-point instructions operate on the lower half of GPRs. These single-precision floating-point instructions do not have a separate register file; there is a single shared register file for all instructions. [Figure 3-18](#) shows two different representations of the 64-bit GPRs. The shaded half is the only region operated on by the 32-bit Power Architecture embedded category instructions.

Figure 3-18. 64-bit General-Purpose Registers

3.3.7 SPE Programming Model

Not all SPE instructions record events such as overflow, saturation, and negative/positive result. See the description of the individual SPE instruction in the e200z6 core reference for information on which conditions are recorded and where they are recorded. Most SPE instructions record conditions to the SPEFSCR. Vector compare instructions store the result of the comparison into the condition register (CR).

The e200z6 core has a 64-bit architectural accumulator register that holds the results of the SPE multiply accumulate (MAC) fixed-point instructions. The accumulator allows back-to-back execution of dependent fixed-point MAC instructions, something that is found in the inner loops of DSP code such as filters. The accumulator is partially visible to the programmer in that its results do not have to be explicitly read to use them. Instead, they are always copied into a 64-bit destination GPR specified as part of the instruction. The accumulator however, has to be explicitly cleared when starting a new MAC loop. Based on the type of instruction, the accumulator can hold either a single 64-bit value or a vector of two 32-bit elements.

3.4 External References

In addition to the Power Architecture instructions, the device supports e200z6 core-specific instructions and SPE APU instructions and VLE instructions. For further information see the following documents:

3.5 Power Architecture Instruction Extensions – VLE

The variable length encoding (VLE) provides an extension to 32-bit Power Architecture. There are additional operations defined using an alternate instruction encoding to enable reduced code footprint. This alternate encoding set is selected on an instruction page basis. A single page attribute bit selects between standard Power Architecture instruction encodings and VLE instructions for that page of memory. This page attribute is an extension to the Power Architecture page attributes. Pages can be freely intermixed, allowing for a mixture of code using both types of encodings.

Instruction encodings in pages marked as using the VLE extension are either 16 or 32 bits long, and are aligned on 16-bit boundaries. Therefore, all instruction pages marked as VLE are required to use big-endian byte ordering.

This section describes the various extensions to the Power Architecture instructions that support the VLE extension.

rfci, rfdi, rfi Not the mask bit 62 of CSRR0, DSRR0, or SRR0 respectively.
The destination address is [D,C]SRR0[32:62] || 0b0.

bclr, bclrl, bcctr, bcctrl Not the mask bit 62 of the LR or CTR respectively.
The destination address is [LR,CTR][32:62] || 0b0.

3.6 Document Revision History

Table 3-12. Changes Between MPC5565RM Revisions 0.1 and 1

Added wording throughout the chapter specifying Power Architecture information. This replaced PowerPC information.
<p>In the reset row of the register figures (Figure 3-7–Figure 3-12), replaced the following:</p> <ul style="list-style-type: none"> • From: “Undefined on <i>m_por</i> assertion, unchanged on <i>p_reset_b</i> assertion” • To: “Power Up — Unchanged on Reset” because <i>m_por</i> and <i>p_reset_b</i> are internal signals.
<p>In Table 3-1 “e200z6 Features Not Supported in the Core” table, changed:</p> <ul style="list-style-type: none"> • From: “The internal Time Base and Decrementer Counters are always enabled in the e200z6 “ • To: “The Decrementer Counters are always enabled in the e200z6” <p>and</p> <ul style="list-style-type: none"> • From: “Timer External Clock is not supported” • To: The timer external clock is not connected to a clock; Do not select the timer external clock.
Corrected order of MAS[3] 26-31 bits.

Chapter 4

Reset

4.1 Introduction

The following reset sources are supported in this MCU:

- Power-on reset
- External reset
- Loss-of-lock reset
- Loss-of-clock reset
- Watchdog timer/debug reset
- JTAG reset
- Checkstop reset
- Software system reset
- Software external reset

All reset sources are processed by the reset controller, which is located in the SIU module. The reset controller monitors the reset input sources, and upon detection of a reset event, resets internal logic and controls the assertion of the $\overline{\text{RSTOUT}}$ pin. The $\overline{\text{RSTOUT}}$ signal may be automatically asserted by writing the SER bit in the SIU_SRCR to 1. The $\overline{\text{RSTOUT}}$ signal stays asserted for a number of system clocks¹ determined by the configuration of the PLL. This does not reset the MCU. All other reset sources initiate an internal reset of the MCU.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\)”](#).

For all reset sources, the BOOTCFG[0:1] and PLLCFG[0:1] signals can be used to determine the boot mode and the configuration of the FMPLL, respectively. If the $\overline{\text{RSTCFG}}$ pin is asserted during reset, the values on the BOOTCFG[0:1] pins are latched in the SIU_RSR 4 clock cycles prior to the negation of the $\overline{\text{RSTOUT}}$ pin, determining the boot mode. The values on the PLLCFG[0:1] pins are latched at the negation of the $\overline{\text{RSTOUT}}$ pin, determining the configuration of the FMPLL. If the $\overline{\text{RSTCFG}}$ pin is negated during reset, the FMPLL defaults to normal operation (PLL enabled) with a crystal reference and the boot mode (latched in the SIU_RSR) is defaulted to internal boot from flash.

The reset status register (SIU_RSR) gives the source of the last reset and indicates whether a glitch has occurred on the RESET pin. The SIU_RSR is updated for all reset sources.

All reset sources initiate execution of the MCU boot assist module (BAM) program with the exception of the software external reset.

1. Unless noted otherwise, the use of ‘clock’ or ‘clocks’ in this section is a reference to the system clock.

The reset configuration halfword (RCHW) provides several basic functions at reset. It provides a means to locate the boot code, determines if flash memory is programmed or erased, enables or disables the watchdog timer, configures the MMU to boot as either classic Power Architecture Book E code or as Freescale VLE code, and if booting externally, sets the bus size. The location of the RCHW is specified by the state of the BOOTCFG[0:1] pins. These pins determine whether the RCHW is located in internal flash, located in external memory, or whether a serial or CAN boot is configured.

Refer to [Section Chapter 2, “Signal Description”](#) for a complete description of the BOOTCFG[0:1] pins.

The BAM program reads the values of the BOOTCFG[0:1] pins from the BOOTCFG field of the SIU_RSR, then reads the RCHW from the specified location and uses the RCHW value to determine and execute the specified boot procedure.

Refer to [Section 4.4.3, “Reset Configuration and Configuration Pins,”](#) for a complete description.

4.2 External Signal Description

4.2.1 Reset Input ($\overline{\text{RESET}}$)

The $\overline{\text{RESET}}$ pin is an active low input that is asserted by an external device during a power-on or external reset. The internal reset signal asserts only if the $\overline{\text{RESET}}$ pin is asserted for 10 clock cycles. Assertion of the $\overline{\text{RESET}}$ pin while the device is in reset causes the reset cycle to start over. The $\overline{\text{RESET}}$ pin also has an associated glitch detector which detects spikes greater than two clocks in duration that fall below the switch point of the input buffer logic.

Refer to [Section 6.4.2.1, “RESET Pin Glitch Detect.”](#)

4.2.2 Reset Output ($\overline{\text{RSTOUT}}$)

The $\overline{\text{RSTOUT}}$ pin is an active low output that uses a push/pull configuration. The $\overline{\text{RSTOUT}}$ pin is driven to the low state by the MCU for all internal and external reset sources.

After the negation of the $\overline{\text{RESET}}$ input, if the PLL is configured for 1:1 (dual controller) mode or bypass mode, the $\overline{\text{RSTOUT}}$ signal is asserted for 16000 clocks, plus four clocks for sampling of the configuration pins. If the PLL is configured for any other operating mode, the $\overline{\text{RSTOUT}}$ signal is asserted for 2400 clocks, plus four clocks for sampling of the configuration pins. The $\overline{\text{RSTOUT}}$ pin is asserted by a write to the SER bit of the system reset control register (SIU_SRCR).

Refer to [Section 11.1.4, “FMPLL Modes of Operation”](#) for details of PLL configuration.

NOTE

During a power on reset, $\overline{\text{RSTOUT}}$ is tri-stated.

4.2.3 Reset Configuration ($\overline{\text{RSTCFG}}$)

The $\overline{\text{RSTCFG}}$ input is used to enable the BOOTCFG[0:1] and PLLCFG[0:1] pins during reset. If $\overline{\text{RSTCFG}}$ is negated during reset, the BOOTCFG and PLLCFG pins are not sampled at the negation of $\overline{\text{RSTOUT}}$. In that case, the default values for BOOTCFG and PLLCFG are used. If $\overline{\text{RSTCFG}}$ is asserted during reset, the values on the BOOTCFG and PLLCFG pins are sampled and configure the boot and FMPLL modes.

4.2.4 Weak Pull Configuration (WKPCFG)

WKPCFG determines whether specified eTPU and EMIOS pins are connected to a weak pullup or weak pulldown during and immediately after reset.

4.2.5 Boot Configuration (BOOTCFG[0:1])

BOOTCFG determines the function and state of the following pins after execution of the BAM reset: $\overline{\text{CS}}$ [0:3], ADDR[8:31], DATA[0:31], $\overline{\text{RD_WR}}$, $\overline{\text{BDIP}}$, $\overline{\text{WE}}$ [0:3], $\overline{\text{OE}}$, $\overline{\text{TS}}$, $\overline{\text{TA}}$, $\overline{\text{TEA}}$.

Refer to the boot modes detailed in Section 6.4.1.1, “Boot Configuration” and in Table 6-138.

4.3 Memory Map/Register Definition

Table 4-1 summarizes the reset controller registers. The base address of the system integration unit is 0xC3F9_0000.

Table 4-1. Reset Controller Memory Map

Address	Register Name	Register Description	Bits
Base + 0x000C	SIU_RSR	Reset status register	32
Base + 0x0010	SIU_SRCR	System reset control register	32

4.3.1 Register Descriptions

This section describes all the reset controller registers. It includes details about the fields in each register, the number of bits per field, the reset value of the register, and the function of the register.

4.3.1.1 Reset Status Register (SIU_RSR)

The reset status register (SIU_RSR) reflects the most recent source, or sources, of reset. This register contains one bit for each reset source. A bit set to logic 1 indicates the type of reset that occurred. Simultaneous reset requests cause more than one bit to be set at the same time. After it is set, the reset source bits in the SIU_RSR remain set until another reset occurs. The SERF bit is set when a software external reset occurs, but no previously set bits in the SIU_RSR are cleared.

Refer to Section 4.3.1.1, “Reset Status Register (SIU_RSR)” for additional information.

The SIU_RSR also contains the values latched at the last reset on the WKPCFG and BOOTCFG[0:1] pins and a $\overline{\text{RESET}}$ input pin glitch flag. The reset glitch flag bit (RGF) is cleared by writing a 1 to the bit. A write of 0 has no effect on the bit state. The SIU_RSR can be read at all times.

Reset

The following figure shows the reset status register:

Address: Base + 0x000C

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	PORS	ERS	LLRS	LCRS	WDRS	CRS	0	0	0	0	0	0	0	0	SSRS	SERF
W																
Reset ¹	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	WKP CFG	0	0	0	0	0	0	0	0	0	0	0	0	BOOTCFG	RGF	
W																
Reset ¹	— ²	0	0	0	0	0	0	0	0	0	0	0	0	— ³	— ³	0

¹ The RESET values for this register are defined for power-on reset only.

² The RESET value of this bit or field is determined by the value latched on the pin or pins at the negation of the last reset.

³ The RESET value of this bit or field is determined by the value latched on the pin or pins at the negation of the last reset. BOOTCFG can also be loaded with a default instead of what is on the pin or pins.

Figure 4-1. Reset Status Register (SIU_RSR)

The following table describes the fields in the reset status register:

Table 4-2. SIU_RSR Field Descriptions

Field	Description
0 PORS	Power-on reset status 0 No power-on reset has occurred. 1 A power-on reset has occurred.
1 ERS	External reset status 0 No external reset has occurred. 1 An external reset has occurred. The ERS bit is also set during a POR event.
2 LLRS	Loss-of-lock reset status 0 No loss-of-lock reset has occurred. 1 A loss-of-lock reset has occurred.
3 LCRS	Loss-of-clock reset status 0 No loss-of-clock reset has occurred. 1 A loss-of-clock reset has occurred due to a loss of the reference or failure of the FMPLL.
4 WDRS	Watchdog timer/debug reset status 0 No watchdog timer or debug reset occurred. 1 A watchdog timer or debug reset occurred.
5 CRS	Checkstop reset status 0 No enabled checkstop reset occurred. 1 An enabled checkstop reset occurred.
6–13	Reserved.
14 SSRS	Software system reset status 0 No software system reset occurred. 1 A software system reset occurred.

Table 4-2. SIU_RSR Field Descriptions (continued)

Field	Description
15 SERF	Software external reset flag 0 No software external reset occurred. 1 A software external reset occurred.
16 WKPCFG	Weak pull configuration pin status 0 WKPCFG pin latched during the last reset was logic 0 and weak pulldown is the default setting. 1 WKPCFG pin latched during the last reset was logic 1 and weak pullup is the default setting.
17–28	Reserved.
29–30 BOOTCFG	Reset configuration pin status. Holds the value of the BOOTCFG[0:1] pins that was latched four clocks before the last negation of the $\overline{\text{RSTOUT}}$ pin, if the RSTCFG pin was asserted. If the $\overline{\text{RSTCFG}}$ pin was negated at the last negation of $\overline{\text{RSTOUT}}$, the BOOTCFG field is set to the value 0b00. The BOOTCFG field is used by the BAM program to determine the location of the reset configuration halfword (RCHW). Refer to Table 4-10 for the RCHW location from the BOOTCFG field value.
31 RGF	$\overline{\text{RESET}}$ glitch flag. Set by the MCU when $\overline{\text{RESET}}$ asserts for more than 2 clocks clock cycles, but less than the minimum $\overline{\text{RESET}}$ assertion time of 10 consecutive clocks to cause a reset. This bit is cleared by the reset controller for a valid assertion of the $\overline{\text{RESET}}$ pin or a power-on reset or a write of 1 to the bit. 0 No glitch was detected on the $\overline{\text{RESET}}$ pin. 1 A glitch was detected on the $\overline{\text{RESET}}$ pin.

4.3.1.2 System Reset Control Register (SIU_SRCR)

The system reset control register (SIU_SRCR) allows software to generate either a software system reset or software external reset. The software system reset causes an internal reset sequence, while the software external reset only asserts the external $\overline{\text{RSTOUT}}$ signal. When written to 1, the SER bit automatically clears after a predetermined number of clock cycles. If the value of the SER bit is 1 and a 0 is written to the bit, the bit is cleared and $\overline{\text{RSTOUT}}$ negates, regardless of the number of clocks that have expired.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

The CRE bit in the SIU_SRCR allows software to enable a checkstop reset. If enabled, a checkstop reset occurs if the checkstop reset input to the reset controller is asserted. The checkstop reset is enabled by default.

Address: Base + 0x0010

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SSR	SER	0	0	0	0	0	0	0	0	0	0	0	0	0	0	CRE	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1 ¹	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

¹ The CRE bit is reset to 1 by POR. Other resets sources do not reset the bit value.

Figure 4-2. System Reset Control Register (SIU_SRCR)

The following table describes the fields in the system reset control register (SIU_SRCR):

Table 4-3. SIU_SRCR Field Descriptions

Field	Description
0 SSR	Software system reset. Writing a 1 to this bit causes an internal reset and assertion of the $\overline{\text{RSTOUT}}$ pin. The bit is automatically cleared by all reset sources except the software external reset. 0 Do not generate a software system reset. 1 Generate a software system reset.
1 SER	Software external reset. Writing a 1 to this bit causes a software external reset. The $\overline{\text{RSTOUT}}$ pin is asserted for a predetermined number of clock cycles (Refer to Section 4.2.2, "Reset Output (RSTOUT)"), but the MCU is not reset. The bit is automatically cleared when the software external reset completes. 0 Do not generate a software external reset. 1 Generate a software external reset.
2–15	Reserved.
16 CRE	Checkstop reset enable Writing a 1 to this bit enables a checkstop reset when the e200z6 core enters a checkstop state. The CRE bit defaults to checkstop reset enabled. This bit is reset at POR. 0 No reset occurs when the e200z6 core enters a checkstop state. 1 A reset occurs when the e200z6 core enters a checkstop state.
17–31	Reserved.

4.4 Functional Description

4.4.1 Reset Vector Locations

The reset vector contains a pointer to the instruction where code execution begins after BAM execution. The address of the reset vector is specified by the boot mode, as listed in [Table 4-4](#).

Table 4-4. Reset Vector Locations

Boot Mode	Reset Vector Location
External Boot	0x0000_0004 (0x0000_0000 is a valid RCHW)
Internal Boot	Next word address after the first valid RCHW located. The BAM searches the lowest address of each of the six low address space blocks in flash memory for a valid RCHW. Hence, the available reset vector addresses are: 0x0000_0004 0x0000_4004 0x0001_0004 0x0001_C004 0x0002_0004 0x0003_0004
Serial Boot	Specified over serial download

4.4.2 Reset Sources

4.4.2.1 FMPLL Lock

A loss of lock of the FMPLL can cause a reset (provided the SIU is enabled by the FMPLL_SYNCR[LOLRE] bit). Furthermore, reset remains asserted, regardless of the reset source, until after the FMPLL locks.

4.4.2.2 Flash High Voltage

There is no flash access gating signal implemented in this device. However, the device is held in reset for a long enough period of time to guarantee that high voltage circuits are reset and stabilized and that flash memory is accessible.

4.4.2.3 Reset Source Descriptions

For the following reset source descriptions refer to the reset flow diagrams in [Figure 4-5](#) and [Figure 4-6](#). [Figure 4-5](#) shows the reset flow when $\overline{\text{RESET}}$ asserts. [Figure 4-6](#) shows the internal reset processing for all reset sources.

4.4.2.3.1 Power-on Reset

The power-on reset (POR) circuit is designed to detect a POR event and ensure that the $\overline{\text{RESET}}$ signal is correctly sensed. The POR is not designed to detect falling power supply voltages. Provide monitoring for external supply. The output signals from the power-on reset circuits are active low signals. All power-on reset output signals are combined into one POR signal at the V_{DD} level and input to the reset controller. Although assertion of the power-on reset signal causes reset, the $\overline{\text{RESET}}$ pin must be asserted during a power-on reset to guarantee proper operation of the MCU.

The PLLCFG[0:1] and $\overline{\text{RSTCFG}}$ pins determine the configuration of the FMPLL. If the $\overline{\text{RSTCFG}}$ pin is asserted at the negation of $\overline{\text{RSTOUT}}$, the PLLCFG[0:1] pins set the operating mode of the FMPLL. If $\overline{\text{RSTCFG}}$ is asserted anytime during the assertion of $\overline{\text{RSTOUT}}$, the FMPLL switches to the mode specified by the PLLCFG[0:1] pins. The values on the $\overline{\text{RSTCFG}}$ and the PLLCFG[0:1] pins must be kept constant after $\overline{\text{RSTCFG}}$ is asserted to avoid transient mode changes in the FMPLL. If $\overline{\text{RSTCFG}}$ is in the negated state at the negation of $\overline{\text{RSTOUT}}$, the FMPLL defaults to enabled with a crystal reference.

Refer to [Chapter 11, “Frequency Modulated Phase Locked Loop and System Clocks \(FMPLL\),”](#) for more details on the operation of the FMPLL and the PLLCFG[0:1] pins.

The signal on the WKPCFG pin determines whether weak pullup or pulldown devices are enabled after reset on the eTPU and eMIOS pins. The WKPCFG pin is applied starting at the assertion of the internal reset signal, as indicated by the assertion of $\overline{\text{RSTOUT}}$.

Refer to [Figure 4-4](#) and see [Chapter 2, “Signal Description,”](#) for information on WKPCFG and $\overline{\text{RSTOUT}}$.

After the $\overline{\text{RESET}}$ input pin is negated, the reset controller checks if the FMPLL is locked. The internal reset signal and $\overline{\text{RSTOUT}}$ are kept asserted until the FMPLL is locked. After the FMPLL is locked, the reset controller waits an additional predetermined number of clock cycles before negating the $\overline{\text{RSTOUT}}$ pin. The WKPCFG and BOOTCFG[0:1] pins are sampled 4 clock cycles before the negation of $\overline{\text{RSTOUT}}$,

and the associated bits/fields are updated in the SIU_RSR (the BOOTCFG[0:1] pins are only sampled if $\overline{\text{RSTCFG}}$ asserts). In addition, the PORs and ERS bits are set, and all other reset status bits are cleared in the reset status register.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

4.4.2.3.2 External Reset

When the reset controller detects assertion of the $\overline{\text{RESET}}$ pin, the internal reset signal and the $\overline{\text{RSTOUT}}$ signal are asserted.

1. Starting when the internal reset signal asserts, as indicated by $\overline{\text{RSTOUT}}$ asserting, the value on the WKPCFG pin is applied. At the same time, the PLLCFG[0:1] values are applied only if $\overline{\text{RSTCFG}}$ asserts.
2. After the $\overline{\text{RESET}}$ signal negates and the FMPLL loss-of-lock request negates, the reset controller waits the predetermined number of clock cycles. After the clock count finishes, WKPCFG and BOOTCFG[0:1] are sampled. BOOTCFG[0:1] is only sampled if $\overline{\text{RSTCFG}}$ asserts.
3. The reset controller then waits four clock cycles before the negating $\overline{\text{RSTOUT}}$, and updating the fields in the SIU_RSR. The ERS bit is set, and all other reset status bits in the SIU_RSR are cleared.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

4.4.2.3.3 Loss-of-Lock Reset

A loss-of-lock reset occurs when the FMPLL loses lock and the loss-of-lock reset enable (LOLRE) bit in the FMPLL synthesizer control register (FMPLL_SYNCR) is set.

1. Starting when the internal reset signal asserts, as indicated by $\overline{\text{RSTOUT}}$ asserting, the value on the WKPCFG pin is applied. At the same time, the PLLCFG[0:1] values are applied only if $\overline{\text{RSTCFG}}$ asserts.
2. After the FMPLL locks, the reset controller waits the predetermined clock count and then samples WKPCFG and BOOTCFG[0:1]. BOOTCFG[0:1] is only sampled if $\overline{\text{RSTCFG}}$ asserts.
3. The reset controller then waits four clock cycles before negating $\overline{\text{RSTOUT}}$ and updating the register fields in the SIU_RSR. The LLRS bit is set, and all other reset status bits in the SIU_RSR are cleared.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

Refer to [Chapter 11, “Frequency Modulated Phase Locked Loop and System Clocks \(FMPLL\),”](#) for more information on loss-of-lock.

4.4.2.3.4 Loss-of-Clock Reset

A loss-of-clock reset occurs when the FMPLL detects a failure in either the reference signal or FMPLL output, and the loss-of-clock reset enable (LOCRE) bit in the FMPLL_SYNCR is set.

The device comes out of loss-of-clock reset using the following sequence:

1. Starting the internal reset signal asserts, as indicated by $\overline{\text{RSTOUT}}$ asserting, the value on the WKPCFG pin is applied. At the same time, the PLLCFG[0:1] values are applied only if $\overline{\text{RSTCFG}}$ is asserted.
2. After the FMPLL has a clock and is locked, the reset controller waits the predetermined clock cycles before negating $\overline{\text{RSTOUT}}$. When the clock count finishes, WKPCFG and BOOTCFG[0:1] are sampled. BOOTCFG[0:1] is only sampled if $\overline{\text{RSTCFG}}$ asserts.
3. The reset controller then waits four clock cycles before negating $\overline{\text{RSTOUT}}$ and updating the fields in SIU_RSR. The LCRS bit is set, and all other reset status bits in the SIU_RSR are cleared.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\)”](#)

Refer to [Section 11.4.2.6, “Loss-of-Clock Detection,”](#) for more information on loss-of-clock.

4.4.2.3.5 Watchdog Timer/Debug Reset

The WDRS bit in the reset status register (SIU_RSR) is set when the watchdog timer or a debug request reset occurs.

A watchdog timer reset occurs and the WDRS bit is set when all the following conditions occur:

- e200z6 core watchdog timer is enabled with the enable next watchdog timer (EWT)
- Watchdog timer interrupt status (WIS) bits are set in the timer status register (TSR)
- Watchdog reset control (WRC) field in the timer control register (TCR) is configured to reset
- Time-out occurs

The debug tool can issue a debug reset command by writing 2'b10 to the RST bit {DBCRC0[2:3]} register in the e200z6 core, which sets the WDRS bit in the reset status register of the systems integration unit (SIU_RSR)

To determine if WDRS was set by a watchdog timer or debug reset, check the WRS field in the e200z6 core TSR.

The effect of a watchdog timer or debug reset request is the same on the reset controller.

The debug tool can also reset the device using one of the following methods:

- Debug tool asserts the $\overline{\text{RESET}}$ signal on the RESET_b pin
- Debug tool sets the software system reset (SSR) bit in the system reset control register (SIU_SRCR)

The debug tool writes a one to the software external reset (SER) bit in the system reset control register (SIU_SRCR) to generate an external software reset.

The device comes out of reset using the following sequence:

1. Starting when the internal reset signal asserts, as indicated by $\overline{\text{RSTOUT}}$ asserting, the value on the WKPCFG pin is applied. At the same time, the PLLCFG[0:1] values are applied only if $\overline{\text{RSTCFG}}$ is asserted.
2. After the FMPLL is locked, the reset controller waits the predetermined number of clock cycles before negating $\overline{\text{RSTOUT}}$. When the clock count finishes, WKPCFG and BOOTCFG[0:1] are sampled. BOOTCFG[0:1] is only sampled if $\overline{\text{RSTCFG}}$ asserts.
3. The reset controller then waits 4 clock cycles before the negating $\overline{\text{RSTOUT}}$, and the associated bits/fields are updated in the SIU_RSR.

Refer to the e200z6 Core Guide for more information on the watchdog timer and debug operation.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

4.4.2.3.6 Checkstop Reset

When the e200z6 core enters a checkstop state, and the checkstop reset is enabled, the CRE bit in the system reset control register (SIU_SRCR) is set and a checkstop reset occurs. Starting when the internal reset signal asserts ($\overline{\text{RSTOUT}}$), the value on the WKPCFG pin is applied; at the same time the PLLCFG[0:1] values are applied if $\overline{\text{RSTCFG}}$ is asserted. After the FMPLL is locked, the reset controller waits a predetermined number of clock cycles before negating $\overline{\text{RSTOUT}}$.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

When the clock count finishes, the WKPCFG and BOOTCFG[0:1] pins are sampled (the BOOTCFG[0:1] pins are only sampled if $\overline{\text{RSTCFG}}$ is asserted). The reset controller then waits four clock cycles before the negating $\overline{\text{RSTOUT}}$, and updating the data in the SIU_RSR. In addition, the CRS bit is set, and all other reset status bits in the SIU_RSR are cleared. Refer to e200z6 Core Guide for more information.

4.4.2.3.7 JTAG Reset

A system reset occurs when JTAG is enabled and either the EXTEST, CLAMP, or HIGHZ instructions are executed by the JTAG controller. Starting at the assertion of the internal reset signal (as indicated by assertion of $\overline{\text{RSTOUT}}$), the value on the WKPCFG pin is applied; at the same time the PLLCFG[0:1] values are applied if $\overline{\text{RSTCFG}}$ is asserted.

After the JTAG reset request has negated and the FMPLL is locked, the reset controller waits a predetermined number of clock cycles before negating $\overline{\text{RSTOUT}}$. When the clock count finishes the WKPCFG and BOOTCFG[0:1] pins are sampled (note that the BOOTCFG[0:1] pins are sampled only if $\overline{\text{RSTCFG}}$ is asserted), and the data is updated in the SIU_RSR. The reset source status bits in the SIU_RSR are unaffected.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

Refer to [Chapter 23, “IEEE 1149.1 Test Access Port Controller \(JTAGC\),”](#) for more information.

4.4.2.3.8 Software System Reset

A software system reset is caused by a write to the SSR bit in the system reset control register (SIU_SRCR). A write of 1 to the SSR bit causes an internal reset of the MCU. The internal reset signal is asserted (as indicated by assertion of $\overline{\text{RSTOUT}}$). The value on the WKPCFG pin is applied starting at the assertion of the internal reset signal (as indicated by assertion of $\overline{\text{RSTOUT}}$); at the same time the PLLCFG[0:1] values are applied if $\overline{\text{RSTCFG}}$ is asserted. After the FMPLL locks, the reset controller waits a predetermined number of clock cycles before negating $\overline{\text{RSTOUT}}$. When the clock count finishes the WKPCFG and BOOTCFG[0:1] pins are sampled (the BOOTCFG[0:1] pins are only sampled if $\overline{\text{RSTCFG}}$ is asserted). The reset controller then waits 4 clock cycles before negating $\overline{\text{RSTOUT}}$, and the associated bits/fields are updated in the SIU_RSR. In addition, the SSRS bit is set, and all other reset status bits in the SIU_RSR are cleared.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

4.4.2.3.9 Software External Reset

A write of 1 to the SER bit in the SIU_SRCR causes the external $\overline{\text{RSTOUT}}$ pin to be asserted for a predetermined number of clocks. The SER bit automatically clears after the clock cycle expires. A software external reset does not cause a reset of the MCU, the BAM program is not executed, the PLLCFG[0:1], BOOTCFG[0:1], and WKPCFG pins are not sampled. The SERF bit in the SIU_RSR is set, but no other status bits are affected. The SERF bit in the SIU_RSR is not automatically cleared after the clock count expires, and remains set until cleared by software or another reset besides the software external reset occurs.

Refer to [Section 4.2.2, “Reset Output \(RSTOUT\).”](#)

For a software external reset, the e200z6 core continues to execute instructions, timers that are enabled continue to operate, and interrupt requests continue to process. The application must ensure devices connected to $\overline{\text{RSTOUT}}$ are not accessed during a software external reset, and determine how to manage MCU resources.

4.4.3 Reset Configuration and Configuration Pins

The microcontroller and the BAM perform a reset configuration that allows certain functions of the MCU to be controlled and configured at reset. This reset configuration is defined by:

- Configuration pins
- A reset configuration halfword (RCHW), if present
- Serial port, if a serial boot is used

The following sections describe these configuration pins and the RCHW.

4.4.3.1 $\overline{\text{RSTCFG}}$ Pin

Table 4-5 shows the $\overline{\text{RSTCFG}}$ pin settings for configuring the MCU to use a default or a custom configuration.

Table 4-5. $\overline{\text{RSTCFG}}$ Settings

$\overline{\text{RSTCFG}}$	Description
1	Use default configuration of: – booting from internal flash – clock source is a crystal on FMPLL
0	Get configuration information from: – BOOTCFG[0:1] – PLLCFG[0:1]

Refer to Chapter 2, “Signal Description” for more information about the $\overline{\text{RSTCFG}}$ pin.

4.4.3.2 WKPCFG Pin (Reset Weak Pullup/Pulldown Configuration)

As shown in Table 4-6, the signal on the WKPCFG pin determines whether specific eTPU and eMIOS pins are connected to weak pullup or weak pulldown devices during and after reset.

For all reset sources except the software external reset, the WKPCFG pin is applied starting when the internal reset signal asserts ($\overline{\text{RSTOUT}}$). If the WKPCFG signal is logic high when $\overline{\text{RSTOUT}}$ asserts, pullup devices are enabled on the eTPU and eMIOS pins. If the WKPCFG signal is logic low when $\overline{\text{RSTOUT}}$ asserts, pulldown devices are enabled on those pins. The value on WKPCFG must remain constant during reset to avoid oscillations on the eTPU and eMIOS pins caused by switching pullup/down states. The final value of WKPCFG is latched four clock cycles before $\overline{\text{RSTOUT}}$ negates. After reset, software can modify the weak pullup/down selection for all I/O pins through the PCRs in the SIU.

Table 4-6. WKPCFG Settings

WKPCFG	Description
0	Weak pulldown applied to eTPU and eMIOS pins at reset
1	Weak pullup applied to eTPU and eMIOS pins at reset

Refer to Chapter 2, “Signal Description” for information about the WKPCFG pin and how the eTPU and eMIOS pins that are affected.

4.4.3.3 BOOTCFG[0:1] Pins (MCU Configuration)

In addition to specifying the RCHW location, the values latched on the BOOTCFG[0:1] pins at reset initialize the internal flash memory enabled/disabled state, and determine whether no arbitration or external arbitration of the external bus interface is selected. Additionally, the RCHW can determine either directly or indirectly how the MMU is configured, how the external bus is configured, the FlexCAN or eSCI module pin configuration, Nexus enabling, and password selection.

Refer to Chapter 2, “Signal Description” for information about the BOOTCFG pins.

4.4.3.4 PLLCFG[0:1] Pins

The PLLCFG pins are explained in [Section 11.1.4, “FMPLL Modes of Operation.”](#)

Table 4-7. Configurations using PLLCFG[0:1] and $\overline{\text{RSTCFG}}$

$\overline{\text{RSTCFG}}$	PLLCFG0	PLLCFG1	Clock Mode	MODE	PLLSEL	PLLREF
1	PLLCFG pins ignored		Crystal reference (default)	1	1	1
0	0	0	Bypass mode	0	0	0
0	0	1	External reference	1	1	0
0	1	0	Crystal reference	1	1	1
0	1	1	Dual controller mode	1	0	0

Refer to [Chapter 2, “Signal Description”](#) for information about the PLLCFG pins.

4.4.3.5 Reset Configuration Halfword

4.4.3.5.1 Reset Configuration Halfword Definition

The RCHW is read from either external memory or internal flash memory. If a valid RCHW is not found, a CAN/SCI boot is initiated. The RCHW is a collection of control bits that specify a minimum MCU configuration after reset and define the desired mode of operation of the BAM program. At reset the RCHW provides a means to locate the boot code, determines if flash memory is programmed or erased, enables or disables the watchdog timer, configures the MMU to boot as either classic Power Architecture Book E code or as Freescale VLE code, and if booting externally, sets the bus size. Refer to the register indicated in RCHW bit descriptions for a description of each control bit.

NOTE

Do not configure the RCHW to a 32-bit bus size for devices with only a 16-bit data bus.

If booting from internal flash or external memory, the application must ensure that RCHW is the correct value for the configuration, and that it resides in that memory location. The boot ID of the RCHW must read 0x5A. `BOOT_BLOCK_ADDRESS` is explained in [Section 15.3.2.2.4, “Read the Reset Configuration Halfword.”](#)

The fields of the RCHW are shown in [Figure 4-3](#).

Figure 4-3. RCHW Fields

The following table describes the fields in the reset configuration halfword:

Table 4-8. Internal Boot RCHW Field Descriptions

Field	Description
0–4	Reserved: These bit values are ignored when the halfword is read. Write to 0 for future compatibility.
5 WTE	<p>Watchdog timer enable.</p> <p>This is used to enable or disable the e200z6 watchdog timer through the BAM program. The configuration of the watchdog timer function is managed through the timer control register (TCR).</p> <p>0 BAM does not write the e200z6 timebase registers (TBU and TBL) nor enable the e200z6 core watchdog timer.</p> <p>1 BAM writes the e200z6 timebase registers (TBU and TBL) to 0x0000_0000_0000_0000 and enables the e200z6 core watchdog timer with a time-out period of 3×2^{17} system clock cycles. (Example: For 8 MHz crystal → 12MHz system clock → 32.7mS time-out. For 20 MHz crystal → 30 MHz system clock → 13.1mS time-out)</p>
6 PS0	<p>Port size.</p> <p>Defines the width of the data bus connected to the memory on $\overline{CS}[0]$. After system reset, $\overline{CS}[0]$ is changed to a 16-bit port by the BAM which fetches the RCHW from either 16- or 32-bit external memories. Then the BAM reconfigures the EBI either as a 16-bit bus or a 32-bit bus, according to the settings of this bit.</p> <p>0 32-bit $\overline{CS}[0]$ port size 1 16-bit $\overline{CS}[0]$ port size</p> <p>Note: Used only in external boot mode. Do not set the port to 32-bits if the device only has a 16-bit data bus.</p>
7 VLE	<p>VLE Code Indicator.</p> <p>This bit is used to configure the MMU for the boot block to execute as either Classic Power Architecture Book E code or as Freescale VLE code.</p> <p>0 = Boot code executes as Classic Power Architecture Book E code 1 = Boot code executes as Freescale VLE code</p>
8–15 BOOTID[0:7]	<p>Boot identifier.</p> <p>This field serves two functions. First, it is used to indicate which block in flash memory contains the boot program. Second, it identifies whether the flash memory is programmed or invalid. The value of a valid boot identifier is 0x5A (0b01011010). The BAM program checks the first halfword of each flash memory block starting at block 0 until a valid boot identifier is found. If all blocks in the low address space of the internal flash are checked and no valid boot identifier is found, then the internal flash is assumed to be invalid and a CAN/SCI boot is initiated. For an external boot, only block 0 is checked for a valid boot identifier, and if not found, a CAN/SCI boot is initiated.</p>

4.4.3.5.2 Invalid RCHW

If the device is configured to boot from internal flash, a valid boot ID must be read at the lowest address of one of the six LAS blocks in internal flash memory. If the device is configured for a boot from external memory, a valid boot ID must be read at 0x0000_0000 of $\overline{CS}[0]$. Refer to [Chapter 15, “Boot Assist Module \(BAM\)”](#) for more information.

If a valid RCHW is not found, a serial boot is initiated. A serial boot does not use a RCHW. The watchdog timer is enabled. For serial boot entered from a failed external boot, the port size remains configured as 16-bits wide. For serial boot entered from a failed internal boot, the external bus is never configured and remains in the reset state of GPIO inputs.

4.4.3.5.3 Reset Configuration Halfword Source

The reset configuration halfword (RCHW) specifies a minimal MCU configuration after reset. The RCHW also contains bits that control the BAM program flow. Refer to [Section 15.3.2.2.4, “Read the Reset Configuration Halfword”](#) for information on the BAM using the RCHW. The RCHW is read and applied each time the BAM program executes, which is for every power-on, external, or internal reset event. The only exception to this is the software external reset.

Refer to [Section 4.4.3.5, “Reset Configuration Halfword,”](#) for detailed descriptions of the bits in the RCHW. The RCHW is read from one of the following locations:

- The lowest address (0x0000_0000) of an external memory device, enabled by chip select $\overline{CS}[0]$ using either a 16- or 32-bit data bus
- The lowest address of one of the six low address space (LAS) blocks in the internal flash memory. (2 x 16K; 2 x 48K; 2 x 64K)

At the negation of the \overline{RSTOUT} pin, the BOOTCFG field in the RSR has been updated. If BOOTCFG[0] is asserted, then the BAM program reads the RCHW from address 0x0000_0000 in the external memory connected to $\overline{CS}[0]$ (the BAM first configures the MMU and $\overline{CS}[0]$ such that address 0x0000_0000 is translated to 0x2000_0000 and then directed to $\overline{CS}[0]$). When BOOTCFG[0] is asserted, BOOTCFG[1] determines whether external arbitration must be enabled to fetch the RCHW.

If BOOTCFG[0] and BOOTCFG[1] negates when \overline{RSTOUT} negates, the BAM program attempts to read the RCHW from the first address of each of the six blocks in the low address space (LAS) of internal flash. [Table 4-9](#) shows the LAS addresses.

Table 4-9. LAS Block Memory Addresses

Block	Address
0	0x0000_0000
1	0x0000_4000
2	0x0001_0000
3	0x0001_C000
4	0x0002_0000
5	0x0003_0000

If the RCHW stored in either internal or external flash is invalid (boot identifier field of RCHW is not 0x5A), or if BOOTCFG[0] negates and BOOTCFG[1] asserts when $\overline{\text{RSTOUT}}$ negates, then RCHW is not applicable, and serial boot mode is invoked. Table 4-10 summarizes the RCHW location options.

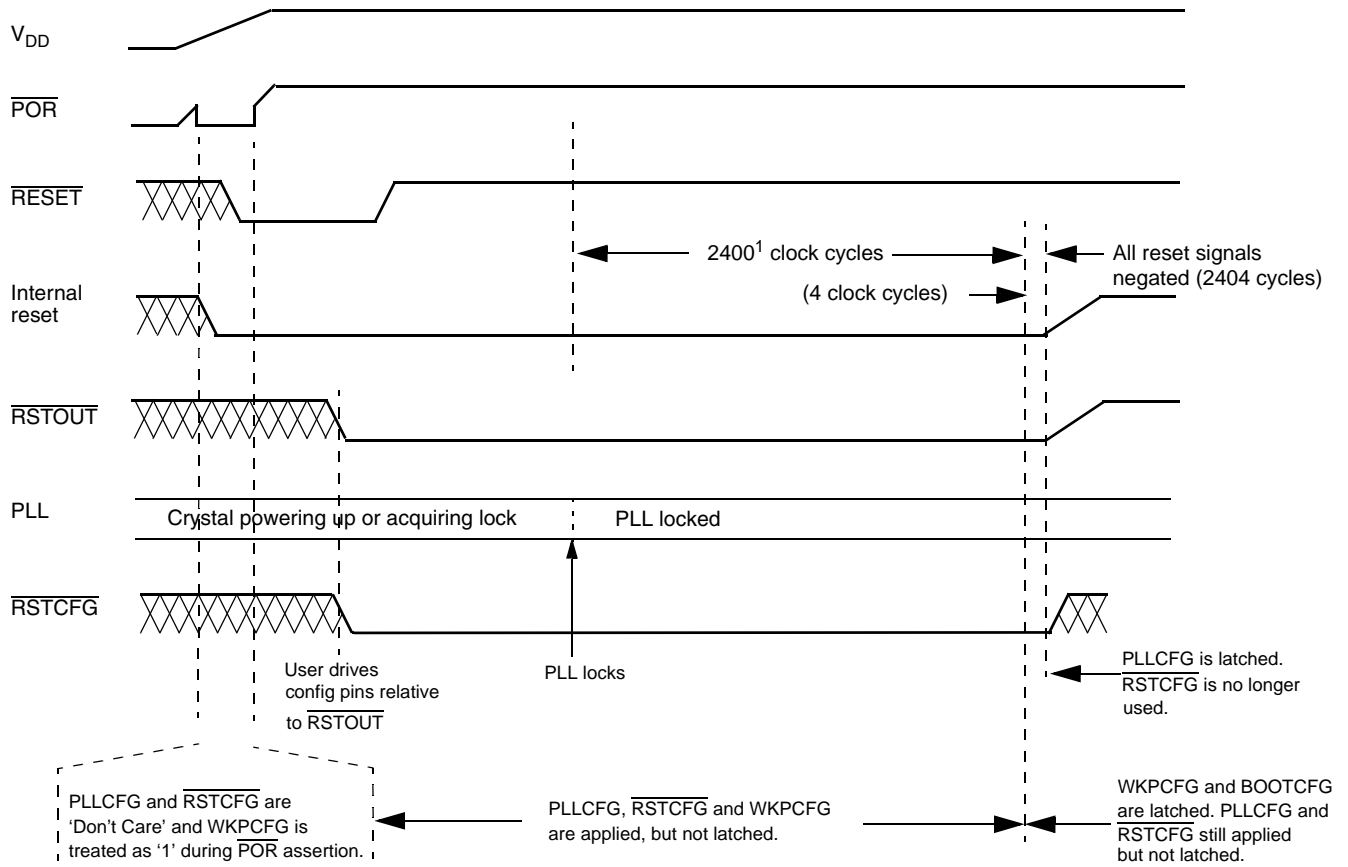

Table 4-10. Reset Configuration Halfword Sources

$\overline{\text{RSTCFG}}$	BOOTCFG[0]	BOOTCFG[1]	Boot Identifier Field (RCHW)	Boot Mode	Configuration Word Source
1	—	—	Valid	Internal	The lowest address of one of the six low address spaces (LAS) in internal flash memory.
			Invalid	Serial	Not applicable
0	0	0	Valid	Internal	The lowest address of one of the six low address spaces (LAS) in internal flash memory.
			Invalid	Serial	Not applicable
0	0	1	—	Serial	Not applicable
0	1	0	Valid	External boot, no arbitration	The lowest address (0x0000_0000) of an external memory device, enabled by chip select $\overline{\text{CS}}[0]$ using either 16- or 32-bit data bus.
			Invalid	Serial	Not applicable
0	1	1	External arbitration not supported		

4.4.4 Reset Configuration Timing

The timing diagram in Figure 4-4 shows the sampling of the BOOTCFG[0:1], WKPCFG, and PLLCFG[0:1] pins for a power-on reset. The timing diagram is also valid for internal/external resets assuming that V_{DD} , V_{DDSYN} , and V_{DDEH6} are within valid operating ranges. The values of the PLLCFG[0:1] pins are latched at the negation of the $\overline{\text{RSTOUT}}$ pin, if the $\overline{\text{RSTCFG}}$ pin is asserted at the negation of $\overline{\text{RSTOUT}}$. The value of the WKPCFG signal is applied at the assertion of the internal reset signal (as indicated by the assertion of $\overline{\text{RSTOUT}}$). The values of the WKPCFG and BOOTCFG[0:1] pins are latched 4 clock cycles before the negation of $\overline{\text{RSTOUT}}$ and stored in the reset status register (SIU_RSR). BOOTCFG[0:1] are latched only if $\overline{\text{RSTCFG}}$ is asserted. WKPCFG is not dependent on $\overline{\text{RSTCFG}}$.

The following figure shows the reset configuration timing:

¹ This clock count is dependent on the configuration of the FMPLL (Refer to Section 4.2.2, "RSTOUT"). If the FMPLL is configured for 1:1 (dual controller) operation or for bypass mode, this clock count is 16000.

Figure 4-4. Reset Configuration Timing

4.4.5 Reset Flow

The following figure shows the process flow used for an external reset:

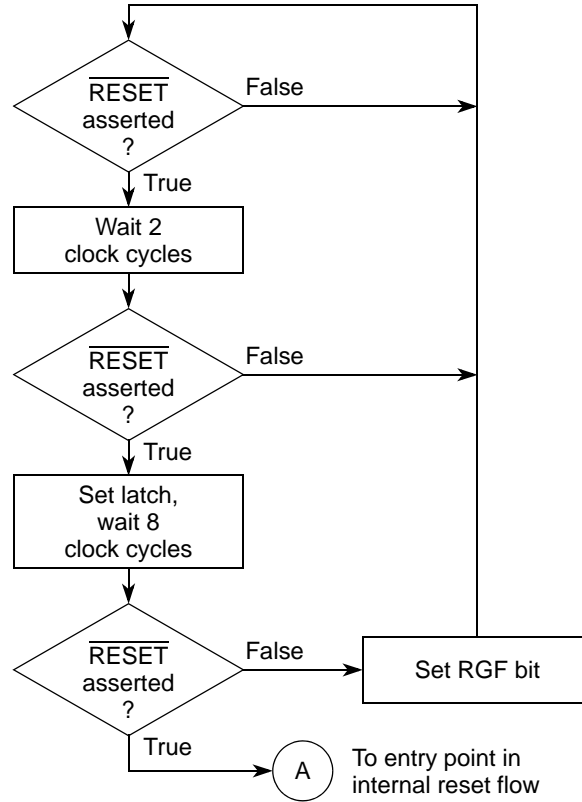

Figure 4-5. External Reset Flow Diagram

The following figure shows the process flow used for an internal reset:

NOTES:

¹ The clock count depends on the FMPLL configuration. Refer to [Section 4.2.2, "Reset Output \(RSTOUT\)"](#). If the FMPLL is configure in dual controller (1:1) or bypass mode, the clock count is 16000.

Figure 4-6. Internal Reset Flow Diagram

4.5 Document Revision History

Table 4-11. Changes Between MPC5565RM Revisions 0.1 and 1

<p>Changed wording throughout the chapter from “PowerPC” to “Power Architecture” to comply with branding requirements.</p>
<p>Changed all addresses to the standard format,</p> <ul style="list-style-type: none"> • From: 0x00_0000 • To: 0x0000_0000.
<p>Rewrote section 4.4.2.3.5, “Watchdog Timer/Debug Reset” and incorporated changes.</p>
<p>Rewrote section 4.4.2.3.5, “Watchdog Timer/Debug Reset to read:</p> <p>The WDRS bit in the reset status register (SIU_RSR) is set when the watchdog timer or a debug request reset occurs.</p> <p>A watchdog timer reset occurs and the WDRS bit is set when all the following conditions occur:</p> <ul style="list-style-type: none"> • e200z6 core watchdog timer is enabled with the enable next watchdog timer (EWT) • Watchdog timer interrupt status (WIS) bits are set in the timer status register (TSR) • Watchdog reset control (WRC) field in the timer control register (TCR) is configured to reset • Time-out occurs <p>The debug tool can issue a debug reset command by writing 2'b10 to the RST bit {DBCR0[2:3]} register in the e200z6 core, which sets the WDRS bit in the reset status register of the systems integration unit (SIU_RSR)</p> <p>To determine if WDRS was set by a watchdog timer or debug reset, check the WRS field in the e200z6 core TSR.</p> <p>The effect of a watchdog timer or debug reset request is the same on the reset controller.</p> <p>The debug tool can also reset the device using one of the following methods:</p> <ul style="list-style-type: none"> • Debug tool asserts the $\overline{\text{RESET}}$ signal on the RESET_b pin • Debug tool sets the software system reset (SSR) bit in the system reset control register (SIU_SRCR) • Debug tool writes a one to the software external reset (SER) bit in the system reset control register (SIU_SRCR) to generate an external software reset <p>The device comes out of reset using the following sequence:</p> <ol style="list-style-type: none"> 1. Starting when the internal reset signal asserts, as indicated by $\overline{\text{RSTOUT}}$ asserting, the value on the WKPCFG pin is applied. At the same time, the PLLCFG[0:1] values are applied only if RSTCFG is asserted. 2. After the FMPLL is locked, the reset controller waits the predetermined number of clock cycles before negating $\overline{\text{RSTOUT}}$. When the clock count finishes, WKPCFG and BOOTCFG[0:1] are sampled. BOOTCFG[0:1] is only sampled if $\overline{\text{RSTCFG}}$ asserts. 3. The reset controller then waits 4 clock cycles before the negating $\overline{\text{RSTOUT}}$, and the associated bits/fields are updated in the SIU_RSR. <p>Refer to the e200z6 Core Guide for more information on the watchdog timer and debug operation.</p> <p>Refer to Section 4.2.2, “Reset Output (RSTOUT).”</p>

Chapter 5

Peripheral Bridge (PBRIDGE_A, PBRIDGE_B)

5.1 Introduction

5.1.1 Block Diagram

The PBRIDGE is the interface between the system bus and on-chip peripherals as shown in [Figure 5-1](#).

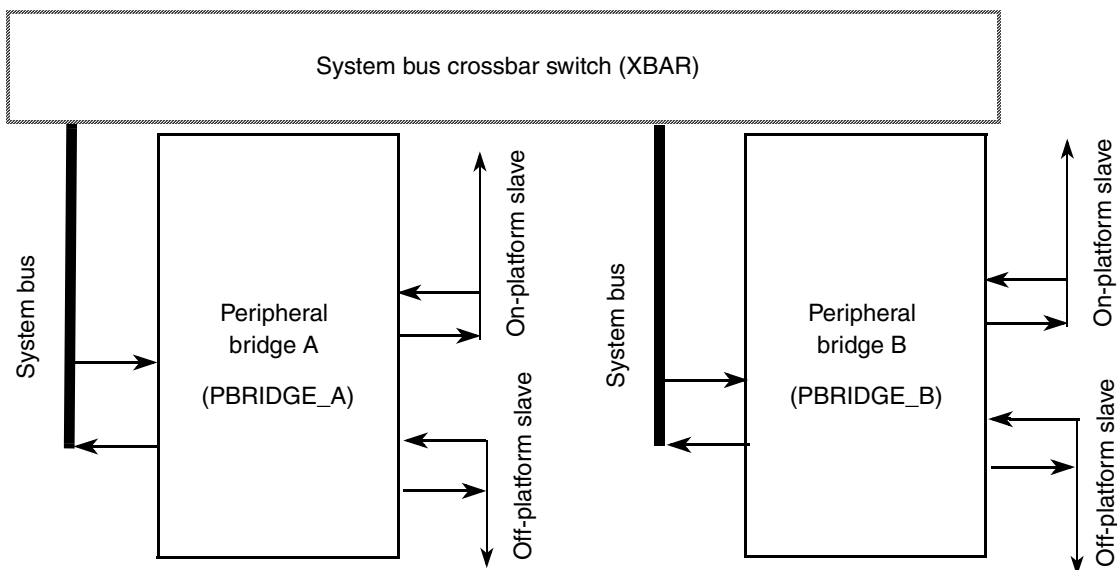

Figure 5-1. PBRIDGE Interface

5.1.2 Overview

There are two peripheral bridges, PBRIDGE_A and PBRIDGE_B, which act as interfaces between the system bus and lower bandwidth peripherals. In this manual, PBRIDGE refers to either of these bridges, as their functionality is identical. The only difference is the peripherals to which they connect. Accesses that fall within the address space of the PBRIDGE are decoded to provide individual module selects for peripheral devices on the slave bus interface.

5.1.2.1 Access Protections

The PBRIDGE provides programmable access protections for both masters and peripherals. Access protections allow the program to:

- Override the privilege level of a master to change it to user mode privilege
- Designate masters as trusted or untrusted

Peripherals can implement the following restrictions:

- Require supervisor privilege level for access
- Restrict access to a trusted master only
- Write-protect the peripheral to deny all access

Refer to [Table 5-1](#) for a list of master/slave IDs and the peripherals for with each master and slave.

Refer to [Section 13.3.2.9, “Flash Bus Interface Unit Access Protection Register \(FLASH_BIUAPR\)”](#) for more information on access protection

Table 5-1. Peripheral Bridge Master/Slave ID Table

			CAN B
			CAN C
BAM			

5.1.3 Features

The following list summarizes the key features of the PBRIDGE:

- Supports the slave interface signals. This interface is only meant for slave peripherals.
- Supports 32-bit slave peripherals. Byte, 16-bit halfword, and 32-bit word reads and writes are supported to each slave peripheral.
- Supports a pair of slave accesses for 64-bit instruction fetches.
- Provides configurable per-module write buffering support.
- Provides configurable per-module and per-master access protections.

5.1.4 Modes of Operation

The PBRIDGE has only one operating mode.

5.2 External Signal Description

The PBRIDGE has no external signals.

5.3 Memory Map and Register Definitions

The memory map for the 32-bit PBRIDGE A registers is shown in [Table 5-2](#).

Table 5-2. PBRIDGE A Memory Map

Address	Register Name	Register Description	Bits
Base (0xC3F0_0000)	PBRIDGE_A_MPCR	Master privilege control register	32
Base + 0x0004– Base + 0x001F	—	Reserved	—
Base + 0x0020	PBRIDGE_A_PACR0	Peripheral access control register 0	32
Base + 0x0024– Base + 0x003F	—	Reserved	—
Base + 0x0040	PBRIDGE_A_OPACR0	Off-platform peripheral access control register 0	32
Base + 0x0044	PBRIDGE_A_OPACR1	Off-platform peripheral access control register 1	32
Base + 0x0048	PBRIDGE_A_OPACR2	Off-platform peripheral access control register 2	32
Base + 0x004C– Base + 0x0053	—	Reserved	—

The memory map for the 32-bit PBRIDGE B registers is shown [Table 5-3](#).

Table 5-3. PBRIDGE B Memory Map

Address	Register Name	Register Description	Bits
Base (0xFFF0_0000)	PBRIDGE_B_MPCR	Master privilege control register	32

Base + 0x0040	PBRIDGE_B_OPACR0	Off-platform peripheral access control register 0	32
Base + 0x0044	PBRIDGE_B_OPACR1	Off-platform peripheral access control register 1	32
Base + 0x0048	PBRIDGE_B_OPACR2	Off-platform peripheral access control register 2	32
Base + 0x004C	PBRIDGE_B_OPACR3	Off-platform peripheral access control register 3	32
Base + 0x0050– Base + 0x0053	—	Reserved	—

5.3.1 Register Descriptions

There are three types of registers that control each PBRIDGE. All registers are 32-bit registers and can only be accessed in supervisor mode by trusted bus masters. Additionally, these registers must only be read from or written to by a 32-bit aligned access. PBRIDGE registers are mapped into the PBRIDGE_A and PBRIDGE_B address spaces. The protection and access fields of the MPCR, PACR, and OPACR registers are 4-bits wide.

5.3.1.1 Master Privilege Control Register (PBRIDGE_x_MPCR)

Each master privilege control register (PBRIDGE_x_MPCR) specifies 4-bit access fields defining the access privilege level associated with a bus master in the platform, as well as specifying whether write accesses from this master are bufferable. The registers provide one field per bus master.

Address: Base + 0x0000

Access: R/W

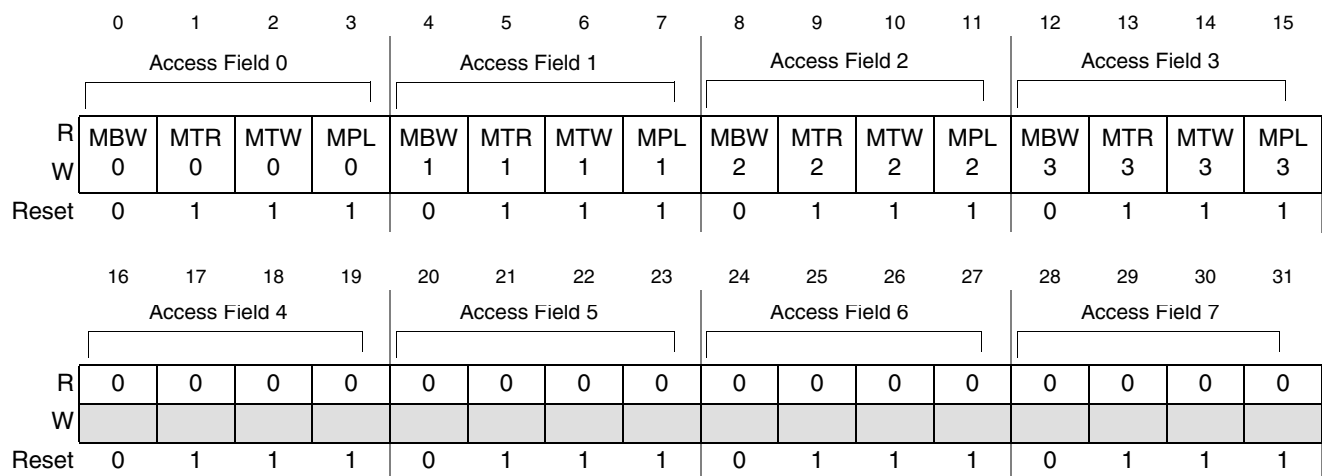

Figure 5-2. Master Privilege Control Registers (PBRIDGE_x_MPCR)

The following table describes the fields in the PBRIDGE X master privilege control register:

Table 5-4. PBRIDGE_x_MPCR Field Descriptions

Field	Description
0 MBW0	Master buffer writes. Determines whether the PBRIDGE is enabled to buffer writes from the CPU. Buffered writes are disabled by default. 0 Buffered write accesses from the CPU are disabled 1 Buffered write accesses from the CPU are enabled
1 MTR0	Master trusted for reads. Determines whether the CPU is trusted for read accesses. Trusted by default. 0 Read accesses from the CPU are not trusted 1 Read accesses from the CPU are trusted
2 MTW0	Master trusted for writes. Determines whether the master is trusted for write accesses. Trusted by default. 0 Write accesses from the CPU are not trusted 1 Write accesses from the CPU are trusted

Table 5-4. PBRIDGE_x_MPCR Field Descriptions (continued)

Field	Description
3 MPL0	Master privilege level. Determines how the privilege level of the CPU is determined. Accesses not forced to user mode by default. 0 Accesses from the CPU are forced to user mode. 1 Accesses from the CPU are not forced to user mode.
4 MBW1	Master buffer writes. Determines whether the PBRIDGE is enabled to buffer writes from the Nexus. Writes not able to be buffered by default. 0 Write accesses from the Nexus are not bufferable 1 Write accesses from the Nexus are allowed to be buffered
5 MTR1	Master trusted for reads. Determines whether the Nexus is trusted for read accesses. Trusted by default. 0 The Nexus is not trusted for read accesses. 1 The Nexus is trusted for read accesses.
6 MTW1	Master trusted for writes. Determines whether the master is trusted for write accesses. Trusted by default. 0 The Nexus is not trusted for write accesses. 1 The Nexus is trusted for write accesses.
7 MPL1	Master privilege level. Determines how the privilege level of the Nexus is determined. Accesses not forced to user mode by default. 0 Accesses from the Nexus are forced to user mode. 1 Accesses from the Nexus are not forced to user mode.
8 MBW2	Master buffer writes. Determines whether the PBRIDGE is enabled to buffer writes from the eDMA. Writes not able to be buffered by default. 0 Write accesses from the eDMA are not bufferable 1 Write accesses from the eDMA are allowed to be buffered
9 MTR2	Master trusted for reads. Determines whether the eDMA is trusted for read accesses. Trusted by default. 0 The eDMA is not trusted for read accesses. 1 The eDMA is trusted for read accesses.
10 MTW2	Master trusted for writes. Determines whether the master is trusted for write accesses. Trusted by default. 0 The eDMA is not trusted for write accesses. 1 The eDMA is trusted for write accesses.
11 MPL2	Master privilege level. Determines how the privilege level of the eDMA is determined. Accesses not forced to user mode by default. 0 Accesses from the eDMA are forced to user mode. 1 Accesses from the eDMA are not forced to user mode.
12 MBW3	Master buffer writes. Determines whether the PBRIDGE is enabled to buffer writes from the EBI. Writes not able to be buffered by default. 0 Write accesses from the EBI are not bufferable 1 Write accesses from the EBI are allowed to be buffered
13 MTR3	Master trusted for reads. Determines whether the EBI is trusted for read accesses. Trusted by default. 0 The EBI is not trusted for read accesses. 1 The EBI is trusted for read accesses.
14 MTW3	Master trusted for writes. Determines whether the master is trusted for write accesses. Trusted by default. 0 The EBI is not trusted for write accesses. 1 The EBI is trusted for write accesses.

Table 5-4. PBRIDGE_x_MPCR Field Descriptions (continued)

Field	Description
15 MPL3	Master privilege level. Determines how the privilege level of the EBI is determined. Accesses not forced to user mode by default. 0 Accesses from the EBI are forced to user mode. 1 Accesses from the EBI are not forced to user mode.
16-31	Reserved

5.3.1.2 Peripheral Access Control Registers (PBRIDGE_x_PACR) and Off-Platform Peripheral Access Control Registers (PBRIDGE_x_OPACR)

Each of the PBRIDGE on-platform peripherals has a 4-bit access field in a peripheral access control register (PACR) that defines the access levels supported by the given module. A single PACR contains up to eight of these module-access fields, and the PACR register structure is shown in [Table 5-2](#) and [Table 5-3](#). The PACR registers with their access fields are shown in [Figure 5-3](#). There are three PACR registers, one for bridge A and two for bridge B.

Also, each of the off-platform peripherals has a 4-bit access field in an off-platform peripheral access control register (PBRIDGE_x_OPACR) that defines the access levels supported by the given module. Each OPACR contains up to eight of these module-access fields, and the OPACR register structure is shown in [Table 5-2](#) and [Table 5-3](#). The OPACR registers with their access fields are shown in [Figure 5-4](#). Seven OPACR registers are used, three for bridge A, and four for bridge B.

NOTE

Not all members of the MPC5500 family have PBRIDGE_x_PACR and PBRIDGE_x_OPACR. On the devices that do not have them, writes to their addresses receive a transfer error. To ensure code compatibility across all the MPC55XX family of products, writes to those addresses must be qualified with SIU_MIDR[PARTNUM].

NOTE

Write PBRIDGE_x_PACR and PBRIDGE_x_OPACR with a read/modify/write for code compatibility.

Peripheral Bridge (PBRIDGE_A, PBRIDGE_B)

The type of peripheral designated by each PACR and OPACR access field is shown in [Table 5-6](#).

Address: Base + 0x0020 (PBRIDGE_A_PACR0 and PBRIDGE_B_PACR0) Access: R/W

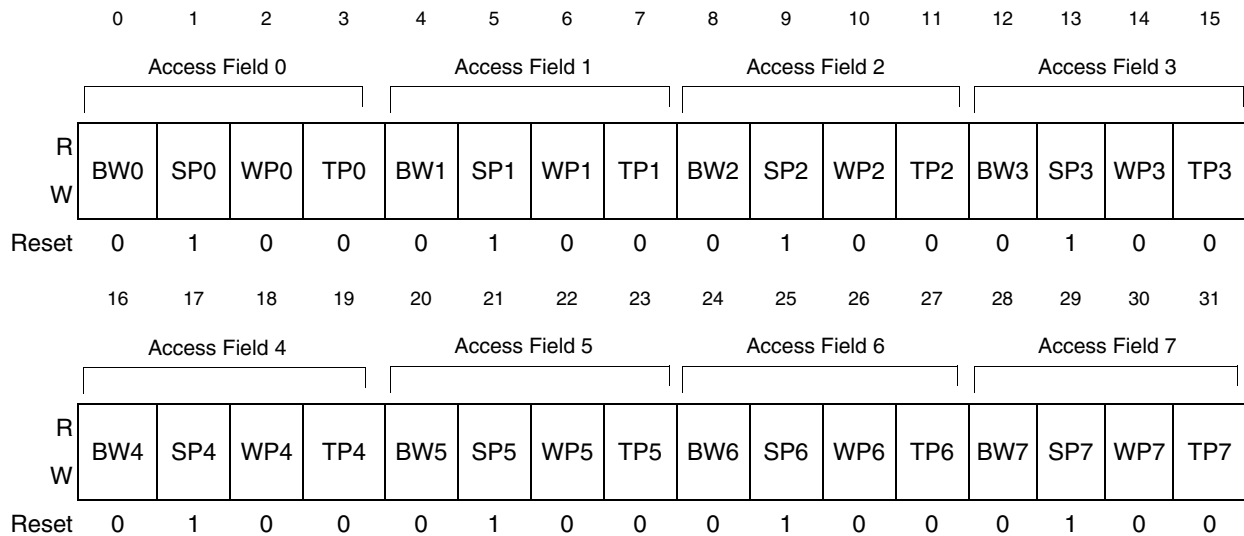

Figure 5-4. Off-platform Peripheral Access Control Registers (PBRIDGE_x_OPACRn)

Table 5-5. PBRIDGE_x_PACRn and PBRIDGE_x_OPACRn Field Descriptions

Field	Description
0, 4, 8, 12, 16, 20, 24, 28 BWn ¹	Buffer writes. Determines whether write accesses to this peripheral are allowed to be buffered. Write accesses not bufferable by default 0 Write accesses to this peripheral are not bufferable by the PBRIDGE. 1 Write accesses to this peripheral are allowed to be buffered by the PBRIDGE. Note: In PBRIDGE_A_PACR0 and PBRIDGE_B_PACR0, the BW0 bit is not writeable.
1, 5, 9, 13, 17, 21, 25, 29 SPn	Supervisor protect. Determines whether the peripheral requires supervisor privilege level for access. Supervisor privilege level required by default. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses. The PBRIDGE_x_MPCR[MPLy] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated on the slave bus.
2, 6, 10, 14, 18, 22, 26, 30 WPn	Write protect. Determines whether the peripheral allows write accesses. Write accesses allowed by default. 0 This peripheral allows write accesses. 1 This peripheral is write protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated on the slave bus.
3, 7, 11, 15, 19, 23, 27, 31 TPn	Trusted protect. Determines whether the peripheral allows accesses from an untrusted master. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated on the slave bus.

¹ In PBRIDGE_A_PACR0 and PBRIDGE_B_PACR0, the BW0 bit is not writeable.

The presence or absence of a module's 4-bit access field in either a PBRIDGE_x_PACR or PBRIDGE_x_OPACR is based on whether the peripheral is present on the device. When absent, the field is not implemented and is read as 0's. Writes are ignored.

NOTE

Table 5-6 lists all of the access fields in the PACRs and OPACRs in both PBRIDGE A and PBRIDGE B, and each of the associated peripherals present on the device.

5.4 Functional Description

The PBRIDGE serves as an interface between a system bus and the peripheral (slave) bus. It functions as a protocol translator. Support is provided for generating a pair of 32-bit peripheral accesses when targeted by a 64-bit system bus access. No other bus-sizing access support is provided.

Accesses that fall within the address space of the PBRIDGE are decoded to provide individual module selects for peripheral devices on the slave bus interface.

5.4.1 Access Support

Aligned 64-bit accesses, aligned word and halfword accesses, as well as byte accesses are supported for 32-bit peripherals. Peripheral registers must not be misaligned, although no explicit checking is performed by the PBRIDGE.

NOTE

Data accesses that cross a 32-bit boundary are not supported.

5.4.2 Peripheral Write Buffering

The PBRIDGE provides programmable write buffering capability to buffer write accesses in the PBRIDGE for later completion, while terminating the system bus access early. This provides improved performance in systems where frequent writes to a slow peripheral occur.

Write buffering is controllable on a per-master and per-peripheral basis. Enable write buffering for masters and peripherals only when an error termination from the slave bus does not occur or is safe to ignore. When write buffering is enabled, all accesses through the PBRIDGE must occur in sequence; bypassing buffered writes is *not* supported.

NOTE

Write buffering causes the processor core to believe that the write has completed before it actually has completed in the peripheral. If write buffering is enabled for a peripheral, the actual write takes an additional two system clock cycles plus any additional system clock cycles that the register needs. Most registers in the MPC5500 family delay the write by two clock cycles, but some registers take longer. This early termination, as seen by the processor core, can defeat the **mbar** or **msync** instruction between the write to clear a flag bit and the write to the INTC_EOIR. Therefore, if write buffering is enabled for a peripheral that has a flag bit, insert instructions between the **mbar** or **msync** instruction and the write to the INTC_EOIR that consumes at least the number of system clock cycles that the actual write is delayed.

Refer to [Section 10.4.3.1.2, “End-of-Interrupt Exception Handler.”](#)

5.4.2.1 Read Cycles

Read accesses are possible with the PBRIDGE when the requested access size is 32-bits or smaller, and is not misaligned across a 32-bit boundary. 64-bit data reads (not instruction) are not supported.

5.4.2.2 Write Cycles

Write accesses are possible with the PBRIDGE when the requested access size is 32-bits or smaller. Misaligned writes that cross a 32-bit boundary are not supported. 64-bit data writes (not instruction) are not supported.

5.4.2.3 Buffered Write Cycles

Single clock write responses to the system bus are possible with the PBRIDGE when the requested write access is bufferable. If the requested access does not violate the permissions check, and if both master and peripheral are enabled for buffering writes, the PBRIDGE internally buffers the write cycle. The write cycle is terminated early with zero system bus wait states. The access proceeds normally on the slave interface, but error responses are ignored.

All accesses are initiated and completed in order on the slave interface, regardless of buffering. If the buffer is full, a following write cycle stalls until it can either be buffered (if bufferable) or can be initiated. If the buffer has valid entries, a following read cycle stalls until the buffer is emptied and the read cycle can be completed.

5.4.3 General Operation

Slave peripherals are modules that contain readable/writable control and status registers. The system bus master reads and writes these registers through the PBRIDGE. The PBRIDGE generates module enables, the module address, transfer attributes, byte enables, and write data as inputs to the slave peripherals. The PBRIDGE captures read data from the slave interface and drives it on the system bus.

Separate interface ports are provided for on-platform and off-platform peripherals. The distinction between on-platform and off-platform is made to allow platform-based designs incorporating the PBRIDGE to separate the interface ports to allow for ease of timing closure. In addition, module selects and control register storage for on-platform peripherals are allocated at synthesis time, allowing only needed resources to be implemented. Off-platform module selects and control register storage do not have the same degree of configurability.

The modules that are on-platform and those that are off-platform are detailed in [Table 5-7](#).

Table 5-7. On-Platform and Off-Platform Peripherals

On-Platform	Off-Platform
Enhanced direct memory access (eDMA)	Deserial serial peripheral interface (DSPI)
PBridge A and B	Enhanced queued analog-to-digital converter (eQADC)
Interrupt controller (INTC)	Enhanced serial communication interface (eSCI)
Error correction status module (ECSM)	FlexCAN controller area network
System bus crossbar switch (XBAR)	Boot assist module (BAM)
	System integration unit (SIU)
	Enhanced modular input/output subsystem (eMIOS)
	Frequency modulated phase locked loop (FMPLL)
	Enhanced time processing unit (eTPU)
	External bus interface (EBI)
	Flash bus interface unit (FBIU)

The PBRIDGE occupies a 64 MB portion of the address space. A 0.5 MB portion of this space is allocated to on-platform peripherals. The remaining 63.5 MB is available for off-platform devices. The register maps of the slave peripherals are located on 16-KB boundaries. Each slave peripheral is allocated one 16-KB block of the memory map, and is activated by one of the module enables from the PBRIDGE. Up to thirty-two 16-KB external slave peripherals can be implemented, occupying contiguous blocks of 16 KBs. Two global external slave module enables are available for the remaining 63 MB of address space to allow for customization and expansion of addressed peripheral devices. In addition, a single non-global module enable is also asserted whenever any of the 32 non-global module enables is asserted.

The PBRIDGE is responsible for indicating to slave peripherals if an access is in supervisor or user mode. The PBRIDGE can block user mode accesses to certain slave peripherals or it can allow the individual slave peripherals to determine if user mode accesses are allowed. In addition, peripherals can be designated as write-protected. The PBRIDGE supports the notion of trusted masters for security purposes.

Peripheral Bridge (PBRIDGE_A, PBRIDGE_B)

Masters can be individually designated as trusted for reads, trusted for writes, or trusted for both reads and writes, as well as being forced to look as though all accesses from a master are in user mode privilege level.

The PBRIDGE also supports buffered writes, allowing write accesses to be terminated on the system bus in a single clock cycle, and then subsequently performed on the slave interface. Write buffering is controllable on a per-peripheral basis. The PBRIDGE implements a two-entry 32-bit write buffer.

5.5 Document Revision History

Table 5-8. Changes Between MPC5565RM Revisions 0.1 and 1

Added a NOTE to Section 5.3.1.2, "Peripheral Access Control Registers (PBRIDGE_x_PACR) and Off-Platform Peripheral Access Control Registers (PBRIDGE_x_OPACR)":

NOTE

Write PBRIDGE_x_PACR and PBRIDGE_x_OPACR with a read/modify/write for code compatibility.

Chapter 6

System Integration Unit (SIU)

6.1 Introduction

This chapter describes the device system integration unit (SIU) that configures and initializes the following controls:

- MCU reset configuration
- System reset operation
- Pad configuration
- External interrupts
- General-purpose I/O (GPIO)
- Internal peripheral multiplexing

6.1.1 Block Diagram

Figure 6-1 is a block diagram of the SIU. One signal, from the muxed signals shown on the right side of the diagram, is assigned to a ball on the device. The SIU registers are accessed through the crossbar switch.

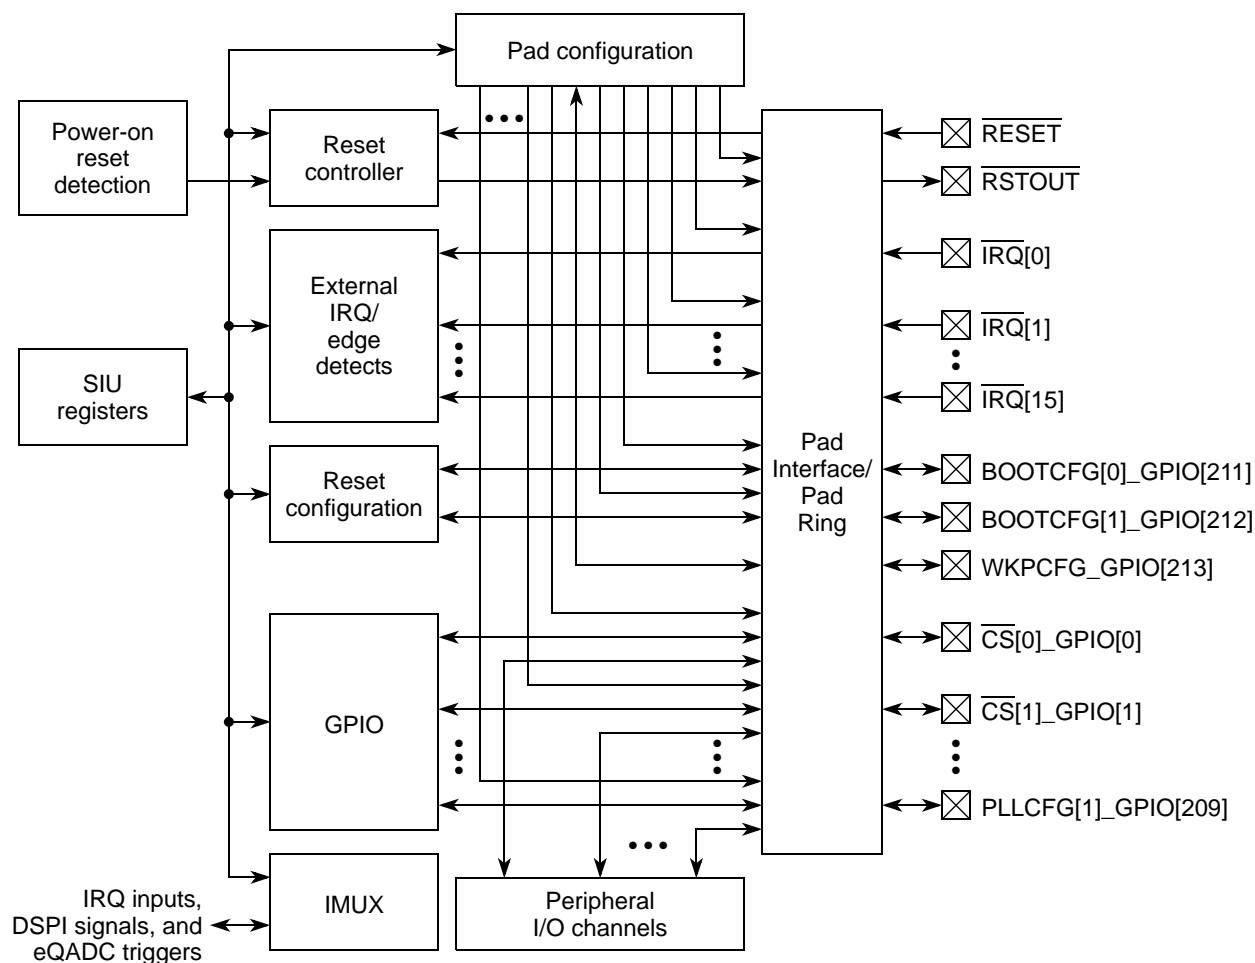

Figure 6-1. SIU Block Diagram

NOTE

The power-on reset detection module, pad interface/pad ring module, and peripheral I/O channels are external to the SIU.

6.1.2 Overview

The system integration unit (SIU) is accessed by the e200z6 core through the system bus crossbar switch (XBAR) and the peripheral bridge A (PBRIDGE_A). Table 6-1 lists the features the SIU configures:

Table 6-1. SIU Features

Feature	Description
MCU reset operations	Controls the external pin boot logic
System reset operations	Monitors internal and external reset sources, and drives the $\overline{\text{RSTOUT}}$ signal <ul style="list-style-type: none"> • Power-on reset support • Reset status register providing last reset source to software • Glitch detection on reset input • Software controlled reset assertion
Pad configuration registers	Enables the configuration and initialization of the I/O pin electrical characteristics via software to select the following: <ul style="list-style-type: none"> • Active function from the set of multiplexed functions • Pullup/down characteristics of the pin • Slew rate for slow and medium pads • Open drain mode for output pins • Hysteresis for input pins • Drive strength of bus signals for fast pads
External interrupt operations	<ul style="list-style-type: none"> • 15 interrupt requests • Rising- or falling-edge event detection • Programmable digital filter for glitch rejection
General-purpose I/O (GPIO)	Provides uniform and discrete I/O control of 178 MCU general-purpose I/O pins, where each GPIO signal has an input register and an output register.
Internal peripheral multiplexing	Provides more flexibility to customize signal/pin assignments for application development which allows: <ul style="list-style-type: none"> • Serial and parallel chaining of DSPIs • Flexible selection of eQADC trigger inputs • Assignment of interrupt requests (IRQs) between external pins and DSPi

6.1.3 Modes of Operation

The MPC5500 family of devices has several operating modes for configuring and testing the chip:

Table 6-2. SIU Operating Modes

Operating Mode	Description
Normal	In normal mode, the SIU provides the register interface and logic that controls the device and system configuration, the reset controller, and GPIO. The SIU continues operation with no changes in stop mode.
Debug	SIU operation in debug mode is identical to operation in normal mode.

6.2 External Signal Description

Table 6-3 lists the external pins used by the SIU.

Table 6-3. SIU Signal Properties

Name	Function	I/O Type	Pad Type	Pullup Pulldown ¹
Resets				
$\overline{\text{RESET}}$	Reset input	Input	—	Up
$\overline{\text{RSTOUT}}$	Reset output	Output	Slow	—
System Configuration				
GPIO[0:210]	General-purpose I/O	I/O	Slow	Up/down
BOOTCFG[0:1] GPIO[211:212]	Boot configuration input General-purpose I/O	Input I/O	Slow	Down Up/down
WKPCFG_ GPIO[213]	Weak-pull configuration General-purpose I/O	Input I/O	Slow	Up Up/down
External Interrupt				
$\overline{\text{IRQ}}[0:5, 7:15]^2$	External interrupt request input	Input	Slow	— ³

¹ Internal weak pullup/down. The reset weak pullup/down state is given by the pullup/down state for the primary signal function. For example, the reset weak pullup/down state of the BOOTCFG[0:1]_GPIO[211:212] signal is weak pulldown enabled.

² The GPIO and IRQ signals are multiplexed with other functions on the device.

³ The weak pullup/down state at reset for the IRQ signals depends on the muxed signals that share the pin. The weak pullup/down state for these pins is as follows:

$\overline{\text{IRQ}}[0, 1, 4, 5, 7, 12, 13, 14]:$	Up
$\overline{\text{IRQ}}[2, 3, 15]:$	Down
$\overline{\text{IRQ}}[8:11]:$	WKPCFG

6.2.1 Detailed Signal Descriptions

6.2.1.1 Reset Input ($\overline{\text{RESET}}$)

$\overline{\text{RESET}}$ is an active-low input signal asserted by an external device during a power-on reset (POR) or external reset. If $\overline{\text{RESET}}$ asserts for 10 clock cycles only, the internal reset signal asserts. Asserting the $\overline{\text{RESET}}$ signal while the device is processing a reset restarts the reset process at the beginning.

$\overline{\text{RESET}}$ has a glitch detector to sense electrical fluctuations that drop below the switch point value of the input buffer logic for the V_{DDEH} inputs for more than two clock cycles.

6.2.1.2 Reset Output ($\overline{\text{RSTOUT}}$)

$\overline{\text{RSTOUT}}$ is an active-low output signal that uses a push/pull configuration. It is driven to the low state by the MCU for all internal and external reset sources. After the $\overline{\text{RESET}}$ input signal negates, $\overline{\text{RSTOUT}}$ asserts for:

- 16000 clock cycles for devices configured in bypass mode
- 16004 clock cycles for devices configured for FMPLL dual-controller mode (1:1)
- 2404 clock cycles for all other FMPLL modes

To invoke an external software reset, write a 1 to the system external reset (SER) bit in the system reset control register (SIU_SRCR). This asserts $\overline{\text{RSTOUT}}$ for 2400 clock cycles. An external software reset does not execute the BAM module or sample BOOTCFG[0:1].

6.2.1.3 General-Purpose I/O (GPIO[0:213])

The GPIO signals provide general-purpose input and output functions. GPIO signals are generally multiplexed with other I/O pin functions. Each GPIO input and output is separately controlled by an eight-bit general-purpose data input (SIU_GPDIn) and a general-purpose data output (SIU_GPDO n) register.

Refer to the following sections for more information:

[Section 6.3.1.151, “GPIO Pin Data Output Registers 0–213 \(SIU_GPDO \$n\$ \)”](#)

[Section 6.3.1.152, “GPIO Pin Data Input Registers 0–213 \(SIU_GPDIn\)”](#)

6.2.1.4 Boot Configuration (BOOTCFG[0:1])

The BOOTCFG value specifies the location and boot mode used by the boot assist module (BAM). All reset sources can read the boot configuration field, BOOTCFG[0:1], except a debug port reset and a software external reset.

The BOOTCFG values are read only if $\overline{\text{RSTCFG}}$ asserts while $\overline{\text{RSTOUT}}$ is asserted. The BOOTCFG signal asserts after $\overline{\text{RSTCFG}}$ to get the boot input information. BOOTCFG[0:1] is sampled four clock cycles before $\overline{\text{RSTOUT}}$ negates, and the latched boot values are stored in the reset status register (SIU_RSR).

If $\overline{\text{RSTCFG}}$ asserts while processing a reset, BOOTCFG[0:1] is sampled. Otherwise, if $\overline{\text{RSTCFG}}$ negates while processing a reset, the following occurs:

1. BOOTCFG[0:1] is not sampled
2. BAM module boots from internal flash (default = 0b00)
3. Boot value from internal flash is written to BOOTCFG[0:1] field in the reset status register (SIU_RSR)
4. BOOTCFG[0:1] values are latched and driven as output signals from the SIU

The BOOTCFG values are used only if the $\overline{\text{RSTCFG}}$ asserts while $\overline{\text{RSTOUT}}$ is asserted. Otherwise, the default value for BOOTCFG (0b00) in the reset status register (SIU_RSR) is used, as shown in Table 6-4.

Table 6-4. BOOTCFG[0:1] Configuration

Value	Meaning
0b00	Boot from internal flash memory (default)
0b01	FlexCAN / eSCI boot
0b10	Boot from external memory (no arbitration)
0b11	Boot from external memory (external arbitration)

6.2.1.5 I/O Weak Pullup Reset Configuration (WKPCFG)

The WKPCFG signal is applied when the internal reset signal asserts (indicated by the assertion of $\overline{\text{RSTOUT}}$), and is sampled four clock cycles before $\overline{\text{RSTOUT}}$ negates. The WKPCFG value configures if the eTPU and eMIOS pins are connected to internal weak pullup or weak pulldown devices after reset. The value of WKPCFG is latched at reset, stored in the reset status register (SIU_RSR), and updated for all reset sources except the debug port reset and software external reset. The WKPCFG value must be valid and not change until $\overline{\text{RSTOUT}}$ negates.

6.2.1.6 External Interrupt Request Input (IRQ)

$\overline{\text{IRQ}}[0:5,7:15]$ connect to the SIU IRQ inputs. The external trigger IRQ select register 1 (SIU_ETISR) specifies the $\overline{\text{IRQ}}[0:5,7:15]$ signals that are input to the SIU IRQs.

External interrupt requests are triggered by rising- and/or falling-edge events that are enabled by setting a bit in:

- IRQ rising-edge event enable register (SIU_IREER)
- IRQ falling-edge event enable register (SIU_IFEER)

If the bit is set in both registers, both rising- and falling-edge events trigger an interrupt request. Each IRQ has a counter that tracks the number of system clock cycles between the rising- and falling-edge events. An IRQ counter exists for each IRQ rising- or falling-edge event enable bit.

The digital filter length field in the IRQ digital filter register (SIU_IDFR) specifies the minimum number of system clocks that the IRQ signal must hold a logic value to qualify the edge-triggered event as a valid state change. When the number of system clocks in the IRQ counter equals the value in the digital filter length field, the IRQ state latches and the IRQ counter is cleared.

If the previous filtered state of the IRQ does not match the current state, and the rising- or falling-edge event is enabled, the IRQ flag bit is set to 1. For example, the IRQ flag bit is set if a rising-edge event occurs under the following conditions:

- Previous filtered IRQ state was a logic 0
- Current latched IRQ state is a logic 1
- Rising-edge event is enabled for the IRQ

When the counter for an IRQ is not enabled, the state of the IRQ is held in the current and previous state latches. The IRQ counter operates independently of the IRQ or overrun flag bit. Clearing the IRQ flag or overrun flag bits does not clear or reload the counter.

Refer to the following sections for more information:

[Section 6.3.1.4, “External Interrupt Status Register \(SIU_EISR\)”](#)

[Section 6.3.1.9, “IRQ Rising-Edge Event Enable Register \(SIU_IREER\)”](#)

[Section 6.3.1.10, “IRQ Falling-Edge Event Enable Register \(SIU_IFEER\)”](#)

[Section 6.3.1.11, “IRQ Digital Filter Register \(SIU_IDFR\)”](#)

6.2.1.6.1 External Interrupts

The IRQ signals map to 16 independent interrupt requests output from the SIU. The IRQ flag bit is set when a rising-edge and/or falling-edge event occurs for the IRQ. An external IRQ signal is asserted when all of the following occur:

- Enable bit is set in the IRQ rising- and/or falling-edge event registers (SIU_IREER, SIU_IFEER)
- IRQ flag bit is set in the external interrupt status register (SIU_EISR)
- Enable bit is cleared in the DMA/interrupt request enable register (SIU_DIRER)
- Select bit is cleared in the DMA/interrupt select register (SIU_DIRSR)

Refer to the following sections for more information:

[Section 6.3.1.5, “DMA/Interrupt Request Enable Register \(SIU_DIRER\)”](#)

[Section 6.3.1.6, “DMA/Interrupt Request Select Register \(SIU_DIRSR\)”](#)

6.2.1.6.2 DMA Transfers

DMA IRQ signals ($\overline{\text{IRQ}}[0]$ through $\overline{\text{IRQ}}[3]$) map to four independent DMA transfer *or* interrupt request outputs configured in the SIU. A DMA transfer or interrupt request asserts when all of the following occur:

- IRQ flag bit is set in the external interrupt status register (SIU_EISR)
- Enable bit is set in the DMA transfer or interrupt request enable register (SIU_DIRER)
- Select bit is set in the DMA transfer or interrupt request select register (SIU_DIRSR)

The SIU receives a ‘DMA transfer done’ signal for each DMA or interrupt request transmitted. When the ‘DMA done’ signal asserts, the IRQ flag bit is cleared.

Refer to the following sections for more information:

[Section 6.3.1.5, “DMA/Interrupt Request Enable Register \(SIU_DIRER\)”](#)

[Section 6.3.1.6, “DMA/Interrupt Request Select Register \(SIU_DIRSR\)”](#)

6.2.1.6.3 Overruns

An overrun IRQ exists for each overrun flag bit in the overrun status register (SIU_OSR).

An overrun IRQ asserts when all of the following occur:

- Enable bit is set in the IRQ rising- and/or falling-edge event registers (SIU_IREER, SIU_IFEER)
- IRQ flag bit is set in the external interrupt status register (SIU_EISR)
- Bit is set in the overrun request enable and overrun status registers (SIU_ORER, SIU_OSR)
- Rising- or falling-edge event triggers an interrupt request

The SIU outputs one overrun IRQ bit that is the logical OR of all of the IRQ overrun bits.

Refer to the following sections for more information:

[Section 6.3.1.4, “External Interrupt Status Register \(SIU_EISR\)”](#)

[Section 6.3.1.7, “Overrun Status Register \(SIU_OSR\)”](#)

[Section 6.3.1.8, “Overrun Request Enable Register \(SIU_ORER\)”](#)

6.2.1.6.4 Edge-Detect Events

An IRQ asserts when an:

- Edge-detect event is enabled
- Edge-detect event occurs

To assert an IRQ when an edge-detect event occurs:

1. Set the enable bit in the IRQ rising- and falling-edge event enable registers (SIU_IREER, SIU_IFEER)
2. Clear the enable bits for the DMA transfer and interrupt request enable register (SIU_DIRER)

The IRQ bit is set in the external IRQ status register (SIU_EISR) when an edge-detect event occurs for that IRQ.

Refer to the following sections for more information:

[Section 6.3.1.4, “External Interrupt Status Register \(SIU_EISR\)”](#)

[Section 6.3.1.9, “IRQ Rising-Edge Event Enable Register \(SIU_IREER\)”](#)

[Section 6.3.1.10, “IRQ Falling-Edge Event Enable Register \(SIU_IFEER\)”](#)

6.3 Memory Map and Register Definition

Table 6-5 is the address map for the SIU registers. All register addresses shown are an offset of the SIU base address.

Table 6-5. SIU Register Address Map

Address	Name	Description	Bits

6.3.1 Register Descriptions

The register figures use the following notational conventions in this section:

w1c	A write of 1 clears the bit to 0.
—	Not applicable.
	Reserved or unimplemented bit.

6.3.1.1 MCU ID Register (SIU_MIDR)

The SIU_MIDR contains the part identification number and mask revision number specific to the device. The part number is a read-only field that is mask programmed with the part number of the device. The part number changes depending on the module versions contained in a device. The part number does not change for bug fixes or process changes.

The mask number is a read-only field that is mask programmed with the specific mask revision level of the device. The current value applies to revision 0 and is updated for each mask revision.

The MCU ID register is 32-bits. [Figure 6-2](#) shows the MCU ID register values.

Table 6-6. SIU_MIDR Field Descriptions

Field	Description
0–15 PARTNUM	MCU part number. Read-only, mask programmed part identification number of the MCU. MPC5565 reads 0x5565.
16 CSP	CSP configuration: 0 Standard package 1 CSP package
17–19 PKG	Package settings. PKG selects the pin package for the MPC5565 device. 000 Select for Legacy compatibility 001–01x Reserved 100 Reserved 101 Selects the 324 package 110 Select the 496 calibration assembly 111 Reserved
20–23	Reserved
24–27 MASKNUM_MAJOR [0:3]	Major revision number of MCU mask. Read-only, mask programmed mask number of the MCU. Reads 0x0 for the initial mask set of the device, and changes sequentially for each mask set.
28–31 MASKNUM_MINOR [0:3]	Minor revision number of MCU mask. Read-only, mask programmed mask number of the MCU. Reads 0x0 for the initial mask set of the device, and changes sequentially for each mask set.

6.3.1.2 Reset Status Register (SIU_RSR)

The SIU_RSR contains the source(s) of the most recent reset, and the state of the configuration pins at reset. Except for a POR request or a software external reset, all reset requests, regardless of priority, are not serviced until the current reset completes.

This register contains one reset status bit for each of the following reset sources:

- Power-on reset (POR)
- External reset
- Software system reset
- Software external reset
- Watchdog reset
- Loss-of-lock reset
- Loss-of-clock reset
- Checkstop reset

A reset status bit set to logic 1 indicates a reset request by that source. After they are set, reset status bits remain set until another reset occurs. Simultaneous reset requests are prioritized. When reset requests of different priorities occur on the same clock cycle, the reset request with the highest priority is serviced and only that reset request's status bit is set.

The following table lists the reset sources and arbitration priorities:

Table 6-7. Reset Source Priorities

Reset Source	Priority	Group
<ul style="list-style-type: none"> Power on reset (POR) External reset 	Highest	0
<ul style="list-style-type: none"> Software system reset 	Higher	1
<ul style="list-style-type: none"> Loss of clock Loss of lock Watchdog Checkstop 	Lower	2
<ul style="list-style-type: none"> Software external reset 	Lowest	3

The WKPCFG bit retains the latest value of the WKPCFG signal before reset. The BOOTCFG field retains the latest values of the BOOTCFG[0:1] signals before reset.

Address: Base + 0x000C

Access: R/W

W																
Reset ¹	U ²	0	0	0	0	0	0	0	0	0	0	0	0	U ³	0	

¹ The reset status register receives the reset values during power-on reset.

² The reset value of the WKPCFG bit is the value on the WKPCFG pin at the time of the last reset.

³ The reset value of the BOOTCFG bits is the value on the BOOTCFG[0:1] pins at the time of the last reset.

Figure 6-3. Reset Status Register (SIU_RSR)

The following table lists and describes the fields of the reset status register:

Table 6-8. SIU_RSR Field Descriptions

Field	Description
0 PORS	<p>Power-on reset status.</p> <p>0 Another reset source was acknowledged by the reset controller since the last assertion of the power-on reset input.</p> <p>1 The power-on reset input to the reset controller was asserted and no other reset source was acknowledged since the assertion of the power-on reset input except an external reset.</p>
1 ERS	<p>External reset status.</p> <p>0 The last reset source acknowledged by the reset controller was not a valid assertion of the $\overline{\text{RESET}}$ pin.</p> <p>1 The last reset source acknowledged by the reset controller was a valid assertion of the $\overline{\text{RESET}}$ pin.</p>

Table 6-8. SIU_RSR Field Descriptions (continued)

Field	Description
2 LLRS	Loss-of-lock reset status. 0 The last reset source acknowledged by the reset controller was not a loss-of-PLL lock reset. 1 The last reset source acknowledged by the reset controller was a loss-of-PLL lock reset.
3 LCRS	Loss-of-clock reset status. 0 The last reset source acknowledged by the reset controller was not a loss-of-clock reset. 1 The last reset source acknowledged by the reset controller was a loss-of-clock reset.
4 WDRS	Watchdog timer/debug reset status. 0 The last reset source acknowledged by the reset controller was not a watchdog timer or debug reset. 1 The last reset source acknowledged by the reset controller was a watchdog timer or debug reset.
5 CRS	Checkstop reset status. 0 The last reset source acknowledged by the reset controller was not an enabled checkstop reset. 1 The last reset source acknowledged by the reset controller was an enabled checkstop reset.
6–13	Reserved
14 SSRS	Software system reset status. 0 The last reset source acknowledged by the reset controller was not a software system reset. 1 The last reset source acknowledged by the reset controller was a software system reset.
15 SERF	Software external reset flag. 0 The software external reset input to the reset controller was not asserted, or this bit has been cleared by writing a 1 to it. 1 The software external reset input to the reset controller was asserted while this bit was 0.
16 WKPCFG	Weak pull configuration pin status 0 The WKPCFG pin value latched during the last reset was a logical 0 and weak pulldown is the default setting. 1 The WKPCFG pin value latched during the last reset was a logical 1 and weak pullup is the default setting.
17–28	Reserved

Table 6-8. SIU_RSR Field Descriptions (continued)

Field	Description
29–30 BOOTCFG	<p>Reset configuration pin status. BOOTCFG[0:1] identifies the address of the reset configuration halfword (RCHW) and whether arbitration is used by the boot assist module (BAM).</p> <p>00 Internal boot mode – lowest address (0x0000_0000) from one of the six LAS fields in internal flash memory. 01 Serial boot mode – lower halfword of the censorship control word. 10 External boot mode – lowest address (0x0000_0000) of external memory as defined by the chip select 0 ($\overline{CS}[0]$) signal with no external arbitration. 11 Invalid value.</p> <p>If \overline{RSTCFG} does not assert before \overline{RSTOUT} negates, and the lower half of the censorship control word (least significant halfword) equals 0xFFFF or 0x0000, the BOOTCFG field is set to 0b10.</p> <p>Otherwise, if the \overline{RSTCFG} pin was negated at the last negation of \overline{RSTOUT}, and the lower half of the censorship control word does not equal 0xFFFF or 0x0000, then the BOOTCFG field is set to the value 0b00.</p> <p>Refer to Table 4-10 for a description of RCHW.</p>
31 RGF	<p>Reset glitch flag. Set by the reset controller when a glitch is detected on the \overline{RESET} pin. This bit is cleared by the assertion of the power-on reset input to the reset controller, or a write of 1 to the RGF bit. Refer to Section 6.4.2.1, “RESET Pin Glitch Detect,” for more information on glitch detection.</p> <p>0 No glitch has been detected on the \overline{RESET} pin. 1 A glitch has been detected on the \overline{RESET} pin.</p>

Except for a POR request or writing a 1 to the software external reset flag (SERF) bit, all reset requests, regardless of priority are not serviced until the current reset completes.

In the following cases, more than one reset bit is set in the reset status register (SIU_RSR):

Table 6-9. Causes That Set Multiple Reset Status Bits

Case 1	
Condition	<ul style="list-style-type: none"> • POR request negates and the device remains in the reset • External reset requested • POR and external reset status bits are set
Reason	POR request started the reset sequence, but an external reset request was received before the POR reset sequence ended.
Case 2	
Condition	<ul style="list-style-type: none"> • Software external reset requested • SERF flag bit set but no previously set bits in the SIU_RSR are cleared
Reason	The SERF flag bit is cleared by writing a 1 (write 1 to clear) to the bit location or when another reset source is asserted.

Table 6-9. Causes That Set Multiple Reset Status Bits (continued)

Case 3	
Condition	<ul style="list-style-type: none"> • Loss-of-clock reset requested • Loss-of-lock reset requested • Watchdog reset requested • Checkstop reset requested
Reason	More than one reset request occurred on the same clock cycle with no reset request by a higher-priority reset source, therefore the status bits for all the requesting resets are set. Refer to Table 6-7 .

6.3.1.3 System Reset Control Register (SIU_SRCR)

The system reset control register configures whether a software system reset or a software external reset is generated. An software system reset uses an internal system reset. An software external reset asserts RSTOUT.

Address: Base + 0x0010

Access: R/W

Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

¹ Write 1 to the SER bit to generate a software external reset. A write of 0 to this bit has no effect. When the reset completes, the SER bit is cleared to 0.

² The SSR bit always reads 0. A write of 0 to this bit has no effect.

³ The CRE bit is set to 1 by POR. Other reset sources cannot set the CRE bit.

Figure 6-4. System Reset Control Register (SIU_SRCR)

The following table describes the fields in the system reset control register:

Table 6-10. SIU_SRCR Field Descriptions

Field	Description
0 SSR	<p>Software system reset. The software system reset is processed as a synchronous reset. Except for a software external reset, the bit automatically clears if any other reset source asserts.</p> <p>0 No software system reset. 1 Generate an software internal system reset.</p>
1 SER	<p>Software external reset. Used to generate a software external reset. Writing a 1 to this bit asserts \overline{RSTOUT} for 2400 clocks, and the internal reset is not asserted. The bit automatically clears when the software external reset completes or any other reset source is asserted. After a software external reset has been initiated, \overline{RSTOUT} negates if this bit is cleared before the 2400 clock period expires.</p> <p>0 Do not generate a software external reset. 1 Generate a software external reset.</p> <p>Note: If the FMPLL is configured for dual controller mode, a write of 1 to the SER bit asserts \overline{RSTOUT} for 16000 clocks. Refer to Section 4.2.2, "Reset Output (RSTOUT)."</p>
2–15	Reserved
16 CRE	<p>Checkstop reset enable. Write a 1 to this bit to enable the checkstop reset request input is asserted. The checkstop reset request input is a synchronous internal reset source. The CRE bit defaults to checkstop reset enabled at POR. If this bit is cleared, it remains cleared until the next POR.</p> <p>0 No reset occurs when the checkstop reset input to the reset controller is asserted. 1 A reset occurs when the checkstop reset input to the reset controller is asserted.</p>
17–31	Reserved

6.3.1.4 External Interrupt Status Register (SIU_EISR)

The external interrupt status register is used to record edge-triggered events on the $\overline{IRQ}[0]–\overline{IRQ}[15]$ inputs to the SIU. When an edge-detect enable bit is set in the SIU_IREER or SIU_IFEER registers for an IRQ, and the IRQ edge-event occurs and is detected, the IRQ flag bit is set in the SIU_EISR.

The IRQ flag bit is set regardless of the state of the DMA or interrupt request enable bit in SIU_DIRER. The IRQ flag bit remains set until cleared by software or through the servicing of a DMA request. The IRQ flag bits are cleared by writing a 1 to the bit. A write of 0 has no effect.

Figure 6-5. External Interrupt Status Register (SIU_EISR)

The following table describes the fields in the external interrupt status register:

Table 6-11. SIU_EISR Field Descriptions

Field	Description
0–15	Reserved
16–31 EIF n	External interrupt request flag n . This bit is set when an edge-triggered event occurs on the corresponding $\overline{IRQ}[n]$ input. Cleared by writing a 1. 0 No edge-triggered event has occurred on the corresponding $\overline{IRQ}[n]$ input. 1 An edge-triggered event has occurred on the corresponding $\overline{IRQ}[n]$ input.

6.3.1.5 DMA/Interrupt Request Enable Register (SIU_DIRER)

The SIU_DIRER asserts a DMA transfer or external interrupt request if the IRQ flag bit is set in the SIU_EISR. The DMA transfer or external interrupt request enable bits (EIRE flags) enable an external interrupt request or DMA transfer request. The SIU uses one interrupt request to the interrupt controller. The EIRE bits determine the external interrupt requests that assert the SIU interrupt request to the interrupt controller.

The following table describes the fields in the DMA interrupt request enable register:

Table 6-12. SIU_DIRER Field Descriptions

Field	Description
0–15	Reserved
16–31 EIRE n	External interrupt request enable n . Enables the assertion of the interrupt request from the SIU to the interrupt controller when an edge-triggered event occurs on the $\overline{\text{IRQ}}[n]$ pin. 0 External interrupt request is disabled. 1 External interrupt request is enabled.

6.3.1.6 DMA/Interrupt Request Select Register (SIU_DIRSR)

The SIU_DIRSR selects between a DMA or interrupt request for events on the $\overline{\text{IRQ}}[0]$ – $\overline{\text{IRQ}}[3]$ inputs. If the IRQ flag bits are set in the external IRQ status register (SIU_EISR) and the DMA/interrupt request enable register (SIU_DIRER), then the select bit in the DMA/interrupt request select register (SIU_DIRSR) determines whether a DMA or interrupt request is asserted.

Figure 6-12. IRQ Digital Filter Register (SIU_IDFR)

The following table describes the field in the IRQ digital filter register:

Table 6-18. SIU_IDFR Field Descriptions

Field	Function
0–27	Reserved
28–31 DFL	Digital filter length. Defines the digital filter period on the $\text{IRQ}n$ inputs according to the following equation: $\text{Filter Period} = (\text{SystemClockPeriod} \times 2^{\text{DFL}}) + 1(\text{SystemClockPeriod})$ For a 100 MHz system clock, this gives a range of 20 ns to 328 μs . The minimum time of three clocks accounts for synchronization of the IRQ input pins with the system clock.

6.3.1.12 Pad Configuration Registers (SIU_PCR)

The following subsections define pad configuration registers (PCR) in the SIU_PCR segment. These registers define the pad configuration for all configurable device pins that specify that active function, direction, and electrical attributes for the pin. The information presented pertains to which bits and fields are active for a given pin or group of pins, and the reset state of the register.

The reset state of SIU_PCRs given in this section is the value before the BAM program executes. The BAM program can change some pad configuration registers based on the reset configuration. Refer to the BAM chapter for more detailed information.

The SIU_PCRs are 16-bit registers that are read from or written to as:

- 16-bit values aligned on 16-bit boundaries, or
- 32-bit values aligned on 32-bit address boundaries.

NOTE

The fields available in a SIU_PCR depend on the type of pad it controls. Refer to the SIU_PCR definition.

All device pin names begin with the primary function, followed by the alternate function, and then GPIO. In some cases, the third function can be a secondary alternate, which supersedes the GPIO. Those exceptions are noted in the documentation. For example, SIU_PCR85 configures the CNTXB_PCSC[3]_GPIO[85] muxed signal, where CNTXB is the primary function, PCSC[3] is the alternate function. For identification of the source module for primary and alternate functions, and the description of these signals, refer to [Chapter 2, “Signal Description”](#) of this manual. Refer to the chapter for the specific module that uses the signal for an additional signal description.

Figure 6-13 shows a sample PCR register with all bit fields displayed:

Figure 6-13. Sample PCR Register Description

The following table describes the fields in the pad configuration control registers:

Table 6-19. SIU_PCR Field Descriptions

Field	Description																																																																																																			
0–2	Reserved																																																																																																			
3–5 PA[0:2]	<p>Pin assignment. Selects the function of a multiplexed pad. A separate port enable output signal from the SIU is asserted for each value of this register. 10 ODE	<p>Open drain output enable. Controls output driver configuration for the pads. Either open drain or push/pull driver configurations can be selected. This feature applies to output pins only.</p> <p>0 Disable open drain for the pad (push/pull driver enabled).</p> <p>1 Enable open drain for the pad.</p>																																																																																																			

Table 6-19. SIU_PCR Field Descriptions (continued)

Field	Description
11 HYS	Input hysteresis. Controls whether hysteresis is enabled for the pad. 0 Disable hysteresis for the pad. 1 Enable hysteresis for the pad.
12–13 SRC[0:1]	Slew rate control. Controls slew rate for the pad. Slew rate control pertains to pins with slow or medium I/O pad types, and the output signals are driven according to the value of this field. Actual slew rate depends on the pad type and load. Refer to the electrical specifications for this information. 00 Minimum slew rate 01 Medium slew rate 10 Invalid value 11 Maximum slew rate
14 WPE	Weak pullup/down enable. Controls whether the weak pullup/down devices are enabled/disabled for the pad. Pullup/down devices are enabled by default. 0 Disable weak pull device for the pad. 1 Enable weak pull device for the pad.
15 WPS	Weak pullup/down select. Controls whether weak pullup or weak pulldown devices are used for the pad when weak pullup/down devices are enabled. The WKPCFG pin determines whether pullup or pulldown devices are enabled during reset. The WPS bit determines whether weak pullup or pulldown devices are used after reset, or for pads in which the WKPCFG pin does not determine the reset weak pullup/down state. 0 Pulldown is enabled for the pad. 1 Pullup is enabled for the pad.

6.3.1.13 Pad Configuration Register 0 (SIU_PCR0)

The SIU_PCR0 register controls the function, direction, and electrical attributes of $\overline{CS}[0_ADDR[8_GPIO[0]$.

Address: Base + 0x0040

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA ¹		OBE ²	IBE ³	DSC		ODE ⁴	HYS	0	0	WPE ⁵	WPS ⁵
W																
RESET:	0	0	0	0	0	0	0	0	1	1	0	0	0	0	1	1

- ¹ Do not configure the PA fields in SIU_PCR[0] and SIU_PCR[4] to ADDR[8]. Configure only one pin to ADDR[8].
- ² When configured as $\overline{CS}[0]$ or ADDR[8], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When configured as $\overline{CS}[0]$, ADDR[8], or GPDO, set the IBE bit to 1 to show the state in the GPDI register. Clearing the IBE bit to 0 reduces power consumption. When configured as GPDI, set the IBE bit to 1.
- ⁴ When configured as $\overline{CS}[0]$ or ADDR[8], clear the ODE bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as $\overline{CS}[0]$ or ADDR[8].

Figure 6-14. $\overline{CS}[0_ADDR[8_GPIO[0]$ Pad Configuration Register (SIU_PCR0)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-20](#) lists the PA values for $\overline{CS}[0]_{_ADDR}[8]_{_GPIO}[0]$.

Table 6-20. PCR0 PA Field Definition

PA Field	Pin Function
0b00	GPIO[0]
0b01	$\overline{CS}[0]$
0b10	ADDR[8]
0b11	$\overline{CS}[0]$

6.3.1.14 Pad Configuration Registers 1–3 (SIU_PCR1–SIU_PCR3)

The SIU_PCR1–SIU_PCR3 registers control the function, direction, and electrical attributes of $\overline{CS}[1:3]_{_ADDR}[9:11]_{_GPIO}[1:3]$.

- ¹ Do not configure the PA fields in PCR1–3 and PCR5–7 to select ADDR[9:11]. Configure only one set of pins to ADDR[9:11] for the address input.
- ² When configured as $\overline{CS}[1:3]$ or ADDR[9:11], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When configured as $\overline{CS}[1:3]$, ADDR[9:11], or GPDO, set the IBE bit to 1 to reflect the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ⁴ When configured as $\overline{CS}[1:3]$ or ADDR[9:11], clear the ODE bit to 0.
- ⁵ If external master operation is enabled, clear the HYS bit to 0.
- ⁶ Refer to the EBI section for weak pullup settings when configured as $\overline{CS}[1:3]$ or ADDR[9:11].

Figure 6-15. $\overline{CS}[1:3]_{_ADDR}[9:11]_{_GPIO}[1:3]$ Pad Configuration Registers (SIU_PCR1–SIU_PCR3)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-21](#) lists the PA values for $\overline{CS}[1:3]_{_ADDR}[9:11]_{_GPIO}[1:3]$.

Table 6-21. PCR1 through PCR3 PA Field Definition

PA Field	Pin Function
0b00	GPIO[1:3]
0b01	$\overline{CS}[1:3]$
0b10	ADDR[9:11]
0b11	$\overline{CS}[1:3]$

6.3.1.15 Pad Configuration Registers 4–7 (SIU_PCR4–SIU_PCR7)

The SIU_PCR4–SIU_PCR7 registers control the function, direction, and electrical attributes of ADDR[8:11]_GPIO[4:7].

Address: Base + 0x0048 through Base + 0x004E

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	PA ¹	OBE ²	IBE ³	DSC	ODE ⁴	HYS ⁵	0	0	WPE ⁶	WPS ⁶	
W																
RESET:	0	0	0	0	0	0	0	0	1	1	0	0	0	0	1	1

- ¹ Do not configure the PA fields in PCR0–3 and PCR4–7 to select ADDR[8:11]. Only configure one set of pins to provide address input.
- ² When configured as ADDR[8:11] the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When configured as ADDR[8:11], or GPDO, set the IBE bit to 1 to reflect the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ⁴ When configured as ADDR[8:11] clear the ODE bit to 0.
- ⁵ If external master operation is enabled, clear the HYS bit to 0.
- ⁶ Refer to the EBI section for weak pullup settings when configured as ADDR[8:11].

Figure 6-16. ADDR[8:11]_GPIO[4:7] Pad Configuration Registers (SIU_PCR4–SIU_PCR7)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-22](#) lists the PA values for ADDR[8:11]_GPIO[4:7].

Table 6-22. PCR4 through PCR7 PA Field Definition

PA Field	Pin Function
0b0	GPIO[4:7]
0b1	ADDR[8:11]

6.3.1.16 Pad Configuration Registers 8–22 (SIU_PCR8–SIU_PCR22)

The SIU_PCR8–SIU_PCR22 registers control the function, direction, and electrical attributes of ADDR[12:26]_GPIO[8:22].

Address: Base + 0x0050 through Base + 0x006C

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

6.3.1.24 Pad Configuration Registers 52 (SIU_PCR52)

The SIU_PCR52 register controls function, direction, and electrical attributes of DATA[24]_GPIO[52].

Address: Base + 0x00A8 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA		OBE ¹	IBE ²	DSC		ODE ³	HYS ⁴	0	0	WPE ⁵ WPS ⁵	
W																
RESET:	0	0	0	0	0	0	0	0	1	1	0	0	0	0	1	1

- ¹ When configured as DATA[24], the OBE bit has no effect.
When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to put the pin state in the GPDI register.
Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as DATA[24], clear the ODE bit to 0.
- ⁴ If external master operation is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as DATA[24].

Figure 6-25. DATA[24]_GPIO[52] Pad Configuration Registers (SIU_PCR52)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-29](#) lists the PA fields for DATA[24]_GPIO[52].

Table 6-29. PCR52 PA Field Definition

PA Field	Pin Function
0b00	GPIO[52]
0b01	DATA[24]
0b10	Invalid value
0b11	DATA[24]

6.3.1.25 Pad Configuration Registers 53 (SIU_PCR53)

The SIU_PCR53 register controls the function, direction, and electrical attributes of DATA[25]_GPIO[53].

Address: Base + 0x00AA Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA		OBE ¹	IBE ²	DSC		ODE ³	HYS ⁴	0	0	WPE ⁵ WPS ⁵	
W																
RESET:	0	0	0	0	0	0	0	0	1	1	0	0	0	0	1	1

- ¹ When configured as DATA[25], the OBE bit has no effect.
When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the corresponding GPDI register.
Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as DATA[25], clear the ODE bit to 0.
- ⁴ If external master operation is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as DATA[25].

Figure 6-26. DATA[25]_GPIO[53] Pad Configuration Registers (SIU_PCR53)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-30](#) lists the PA fields for DATA[25]_GPIO[53].

Table 6-30. PCR53 PA Field Definition

PA Field	Pin Function
0b00	GPIO[53]
0b01	DATA[25]
0b10	Invalid value
0b11	DATA[25]

6.3.1.26 Pad Configuration Registers 54 (SIU_PCR54)

The SIU_PCR54 register controls the function, direction, and electrical attributes of DATA[26]_GPIO[54].

Address: Base + 0x00AC

Access: R/W

- ¹ When configured as DATA[26], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to reflect the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as DATA[26], clear the ODE bit to 0.
- ⁴ If external master operation is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as DATA[26].

Figure 6-27. DATA[26]_GPIO[54] Pad Configuration Registers (SIU_PCR54)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-31](#) lists the PA fields for DATA[26]_GPIO[54].

Table 6-31. PCR54 PA Field Definition

PA Field	Pin Function
0b00	GPIO[54]
0b01	DATA[26]
0b10	Invalid value
0b11	DATA[26]

6.3.1.27 Pad Configuration Registers 55 (SIU_PCR55)

The SIU_PCR55 register controls the function, direction, and electrical attributes of DATA[27]_GPIO[55].

- ¹ When configured as DATA[27], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 shows the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as DATA[27], clear the ODE bit to 0.
- ⁴ If external master operation is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as DATA[27].

Figure 6-28. DATA[27]_GPIO[55] Pad Configuration Registers (SIU_PCR55)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-32](#) lists the PA fields for DATA[27]_GPIO[55].

Table 6-32. PCR55 PA Field Definition

PA Field	Pin Function
0b00	GPIO[55]
0b01	DATA[27]
0b10	Reserved
0b11	DATA[27]

6.3.1.28 Pad Configuration Registers 56 (SIU_PCR56)

The SIU_PCR56 register controls the function, direction, and electrical attributes of DATA[28]_GPIO[56].

- ¹ When configured as DATA[28], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as DATA[28], clear the ODE bit to 0.
- ⁴ If external master operation is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as DATA[28].

Figure 6-29. DATA[28]_GPIO[56] Pad Configuration Registers (SIU_PCR56)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-33](#) lists the PA fields for DATA[28]_GPIO[56].

Table 6-33. PCR56 PA Field Definition

PA Field	Pin Function

6.3.1.29 Pad Configuration Registers 57 (SIU_PCR57)

The SIU_PCR57 register controls the function, direction, and electrical attributes of DATA[29]_GPIO[57].

Address: Base + 0x00B2

Access: R/W

- ¹ When configured as DATA[29], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as DATA[29], clear the ODE bit to 0.
- ⁴ If external master operation is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as DATA[29].

Figure 6-30. DATA[29]_GPIO[57] Pad Configuration Registers (SIU_PCR57)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-34](#) lists the PA fields for DATA[29]_GPIO[57].

Table 6-34. PCR57 PA Field Definition

PA Field	Pin Function
0b00	GPIO[57]

0b10	Invalid value
0b11	DATA[31]

6.3.1.32 Pad Configuration Registers 60–61 (SIU_PCR60–SIU_PCR61)

The SIU_PCR60–SIU_PCR61 registers are *not* implemented in the device.

6.3.1.33 Pad Configuration Register 62 (SIU_PCR62)

The SIU_PCR62 register controls the function, direction, and electrical attributes of RD_̄WR_GPIO[62].

- ¹ When configured as RD_̄WR, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as RD_̄WR, clear the ODE bit to 0.
- ⁴ When external master operation is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as RD_̄WR.

Figure 6-33. RD_̄WR_GPIO[62] Pad Configuration Register (SIU_PCR62)

6.3.1.34 Pad Configuration Register 63 (SIU_PCR63)

The SIU_PCR63 register controls the function, direction, and electrical attributes of ̄BDIP_GPIO[63].

- ¹ When configured as ̄BDIP, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as ̄BDIP, clear the ODE bit to 0.
- ⁴ Refer to the EBI section for weak pullup settings when configured as ̄BDIP.

Figure 6-34. ̄BDIP_GPIO[63] Pad Configuration Register (SIU_PCR63)

6.3.1.35 Pad Configuration Registers 64–65 (SIU_PCR64–SIU_PCR65)

The SIU_PCR64–SIU_PCR65 registers control the function, direction, and electrical attributes of $\overline{WE}/\overline{BE}[0:1]_{GPIO}[64:65]$. The PA bit in PCR registers 64–65 selects between the write/byte enable functions and the GPIO functions. The WEBS bit in the EBI base registers selects between the write-enabled function and byte-enabled function.

Address: Base + 0x00C0 through Base + 0x00C2														Access: R/W		
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
RESET:	0	0	0	0	0	0	0	0	1	1	0	0	0	0	1	1

- ¹ When configured as \overline{TS} , the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as \overline{TS} , clear the ODE bit to 0.
- ⁴ When EBI is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as \overline{TS} .

Figure 6-38. \overline{TS} _GPIO[69] Pad Configuration Register (SIU_PCR69)

6.3.1.39 Pad Configuration Register 70 (SIU_PCR70)

The SIU_PCR70 register controls the function, direction, and electrical attributes of the $\overline{\text{TA}}_{\text{GPIO}}[70]$.

- ¹ When configured as $\overline{\text{TA}}$, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as $\overline{\text{TA}}$ and external master operation is enabled, clear the ODE bit to 0.
- ⁴ When EBI is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as $\overline{\text{TA}}$.

Figure 6-39. $\overline{\text{TA}}_{\text{GPIO}}[70]$ Pad Configuration Register (SIU_PCR70)

6.3.1.40 Pad Configuration Register 71 (SIU_PCR71)

The SIU_PCR71 register controls the function, direction, and electrical attributes of $\overline{\text{TEA}}_{\text{GPIO}}[71]$.

- ¹ When configured as $\overline{\text{TEA}}$, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ³ When configured as $\overline{\text{TEA}}$ and external master operation is enabled, clear the ODE bit to 0.
- ⁴ When EBI is enabled, clear the HYS bit to 0.
- ⁵ Refer to the EBI section for weak pullup settings when configured as $\overline{\text{TEA}}$.

Figure 6-40. $\overline{\text{TEA}}_{\text{GPIO}}[71]$ Pad Configuration Register (SIU_PCR71)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-38](#) lists the PA fields for $\overline{\text{TEA}}_{\text{GPIO}}[71]$.

Table 6-38. PCR71 PA Field Definition

PA Field	Pin Function
0b0	GPIO[71]
0b1	$\overline{\text{TEA}}$

6.3.1.41 Pad Configuration Register 72 (SIU_PCR72)

The SIU_PCR72 register controls the function, direction, and electrical attributes of $\overline{\text{BR}}_{\text{GPIO}}[72]$. This register allows selection of the GPIO functions.

- ¹ The $\overline{\text{BR}}$ function (0b1) is disabled in the device.
- ² When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ⁴ When EBI is enabled, clear the HYS bit to 0.

Figure 6-41. $\overline{\text{BR}}_{\text{GPIO}}[72]$ Pad Configuration Register (SIU_PCR72)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-39](#) lists the PA field for $\overline{\text{BR}}_{\text{GPIO}}[72]$.

Table 6-39. PCR72 PA Field Definition

PA Field	Pin Function
0b0	GPIO[72]
0b1	Invalid value

6.3.1.42 Pad Configuration Register 73 (SIU_PCR73)

The SIU_PCR73 register controls the function, direction, and electrical attributes of $\overline{\text{BG}}_{\text{GPIO}}[73]$. This register allows selection of GPIO functions.

- ¹ The $\overline{\text{BG}}$ function (0b1) is disabled in the device.
- ² When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ⁴ When EBI is enabled, clear the HYS bit to 0.

Figure 6-42. $\overline{\text{BG}}_{\text{GPIO}}[73]$ Pad Configuration Register (SIU_PCR73).

Refer to [Table 6-19](#) for bit field definitions. [Table 6-40](#) lists the PA field for $\overline{\text{BG}}_{\text{FEC_MDIO_GPIO}}[73]$.

Table 6-40. PCR73 PA Field Definition

PA Field	Pin Function
0b00	GPIO[73]
0b01	Invalid value
0b10	Invalid value
0b11	Invalid value

6.3.1.43 Pad Configuration Register 74 (SIU_PCR74)

SIU_PCR[74] register is not implemented in the device.

6.3.1.44 Pad Configuration Register 82–75 (SIU_PCR82–SIU_PCR75)

The SIU_PCR82–SIU_PCR75 registers control the function, direction, and electrical attributes of MDO[11:4]_GPIO[82:75]. GPIO is the default function at reset.

The Full Port Mode (FPM) bit in the Nexus Port Controller (NPC) pad configuration register controls whether the pins function as MDO[11:4] or GPIO[82:75]. The pad interface port enable is driven by the NPC block. When the FPM bit is set, the NPC enables the MDO port enable, and disables GPIO. When the FPM bit is cleared, the NPC disables the MDO port enable, and enables GPIO.

Address: Base + 0x00E4 through Base + 0x00D6 Access: R/W

0b10	TXDA
0b11	CNTXA

6.3.1.46 Pad Configuration Register 84 (SIU_PCR84)

The SIU_PCR84 register controls the pin function, direction, and electrical attributes of CNRXA_RXDA_GPIO[84].

- ¹ When configured as CNRXA or RXDA, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-45. CNRXA_RXDA_GPIO[84] Pad Configuration Register (SIU_PCR84)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-42](#) lists the PA fields for CNRXA_RXDA_GPIO[84].

Table 6-42. PCR84 PA Field Definition

PA Field	Pin Function
0b00	GPIO[83]
0b01	CNRXA
0b10	RXDA
0b11	CNRXA

6.3.1.47 Pad Configuration Register 85 (SIU_PCR85)

The SIU_PCR85 register controls the function, direction, and electrical attributes of CNTXB_PCSC[3]_GPIO[85]. This register allows selection of the CNTXB, PCSC[3] and GPIO functions.

- ¹ When configured as CNTXB or PCSC[3], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-46. CNTXB_PCSC[3]_GPIO[85] Pad Configuration Register (SIU_PCR85)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-43](#) lists the PA fields for CNTXB_PCSC[3]_GPIO[85].

Table 6-43. PCR85 PA Field Definition

PA Field	Pin Function
0b00	GPIO[85]
0b01	CNTXB
0b10	PCSC[3]
0b11	CNTXB

6.3.1.48 Pad Configuration Register 86 (SIU_PCR86)

The SIU_PCR86 register controls the function, direction, and electrical attributes of CNRXB_PCSC[4]_GPIO[86]. This register allows selection of the CNRXB_PCSC[4] and GPIO functions.

Address: Base + 0x00EC

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA		OBE ¹	IBE ²	0	0	ODE	HYS	SRC		WPE	WPS
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

¹ When configured as CNTXB or PCSC[4], the OBE bit has not effect. When configured as GPDO, set the OBE bit to 1.

² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPD1 register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPD1, set the IBE bit to 1.

Figure 6-47. CNRXB_PCSC[4]_GPIO[86] Pad Configuration Register (SIU_PCR86)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-44](#) lists the PA fields for CNRXB_PCSC[4]_GPIO[86].

Table 6-44. PCR86 PA Field Definition

PA Field	Pin Function
0b00	GPIO[86]
0b01	CNTXB
0b10	PCSC[4]
0b11	CNTXB

6.3.1.49 Pad Configuration Register 87 (SIU_PCR87)

The SIU_PCR87 register controls the function, direction, and electrical attributes of CNTXC_PCSD[3]_GPIO[87].

- ¹ When configured as CNTXC or PCSD[3], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-48. CNTXC_PCSD[3]_GPIO[87] Pad Configuration Register (SIU_PCR87)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-45](#) lists the PA fields for CNTXC_PCSD[3]_GPIO[87].

Table 6-45. PCR87 PA Field Definition

PA Field	Pin Function
0b00	GPIO[87]
0b01	CNTXC
0b10	PCSD[3]
0b11	CNTXC

6.3.1.50 Pad Configuration Register 88 (SIU_PCR88)

The SIU_PCR88 register controls the function, direction, and electrical attributes of CNRXC_PCSD[4]_GPIO[88].

- ¹ When configured as CNRXC or PCSD[4], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-49. CNRXC_PCSD[4]_GPIO[88] Pad Configuration Register (SIU_PCR88)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-46](#) lists the PA fields for CNRXC_PCSO[4]_GPIO[88].

Table 6-46. PCR88 PA Field Definition

PA Field	Pin Function
0b00	GPIO[88]
0b01	CNRXC
0b10	PCSD[4]
0b11	CNRXC

6.3.1.51 Pad Configuration Register 89 (SIU_PCR89)

The SIU_PCR89 register controls the function, direction, and electrical attributes of TXDA_GPIO[89].

Address: Base + 0x00F2 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0	0	0	0	0	PA	OBE ¹	IBE ²	0	0	ODE	HYS	SRC	WPE	WPS		
W																	
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	

¹ When configured as TXDA, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.

² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured for eSCI loop back operation or GPDI, set the IBE bit to 1.

Figure 6-50. TXDA_GPIO[89] Pad Configuration Register (SIU_PCR89)

6.3.1.52 Pad Configuration Register 90 (SIU_PCR90)

The SIU_PCR90 register controls the function, direction, and electrical attributes of RXDA_GPIO[90].

Address: Base + 0x00F4 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0	0	0	0	0	PA	OBE ¹	IBE ²	0	0	ODE	HYS	SRC	WPE	WPS		
W																	
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	

¹ When configured as RXDA, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.

² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-51. RXDA_GPIO[90] Pad Configuration Register (SIU_PCR90)

6.3.1.53 Pad Configuration Register 91 (SIU_PCR91)

The SIU_PCR91 register controls the function, direction, and electrical attributes of TXDB_PCSD[1]_GPIO[91].

- ¹ When configured as TXDB or PCSD[1], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured for eSCI loop back operation or GPDI, set the IBE bit to 1.

Figure 6-52. TXDB_PCSD[1]_GPIO[91] Pad Configuration Register (SIU_PCR91)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-47](#) lists the PA fields for TXDB_PCSD[1]_GPIO[91].

Table 6-47. PCR91 PA Field Definition

PA Field	Pin Function
0b00	GPIO[91]
0b01	TXDB
0b10	PCSD[1]
0b11	TXDB

6.3.1.54 Pad Configuration Register 92 (SIU_PCR92)

The SIU_PCR92 register controls the function, direction, and electrical attributes of RXDB_PCSD[5]_GPIO[92].

- ¹ When configured as RXDB or PCSD[5], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-53. RXDB_PCSD[5]_GPIO[92] Pad Configuration Register (SIU_PCR92)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-48](#) lists the PA fields for RXDB_PCSD[5]_GPIO[92].

Table 6-48. PCR92 PA Field Definition

PA Field	Pin Function
0b00	GPIO[92]
0b01	RXDB
0b10	PCSD[5]
0b11	RXDB

6.3.1.55 Pad Configuration Register 93 (SIU_PCR93)

The SIU_PCR93 register controls the function, direction, and electrical attributes of SCKA_PCSC[1]_GPIO[93]. This register allows selection of the PCSC[1] and GPIO functions.

Address: Base + 0x00FA

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA ¹		OBE ²	IBE ³	0	0	ODE	HYS	SRC		WPE	WPS
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

¹ The SCKA function is not available on the device. Do not select 0b01 or 0b11 for the PA field.

² When configured as PCSC[1], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.

³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-54. SCKA_PCSC[1]_GPIO[93] Pad Configuration Register (SIU_PCR93)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-49](#) lists the PA fields for SCKA_PCSC[1]_GPIO[93].

Table 6-49. PCR93 PA Field Definition

PA Field	Pin Function
0b00	GPIO[93]
0b01	Invalid value
0b10	PCSC[1]
0b11	Invalid value

6.3.1.56 Pad Configuration Register 94 (SIU_PCR94)

The SIU_PCR94 register controls the function, direction, and electrical attributes of SINA_PCSC[2]_GPIO[94]. This register allows selection of the PCSC[2] and GPIO functions.

- ¹ The SINA function is not available on the device. Do not select 0b01 or 0b11 for the PA field.
- ² When configured as PCSC[2], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-55. SINA_PCSC[2]_GPIO[94] Pad Configuration Register (SIU_PCR94)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-50](#) lists the PA fields for SINA_PCSC[2]_GPIO[94].

Table 6-50. PCR94 PA Field Definition

PA Field	Pin Function
0b00	GPIO[94]
0b01	Invalid value
0b10	PCSC[2]
0b11	Invalid value

6.3.1.57 Pad Configuration Register 95 (SIU_PCR95)

The SIU_PCR95 register controls the function, direction, and electrical attributes of SOUTA_PCSC[5]_GPIO[95]. This register allows selection of the PCSC[5] and GPIO functions.

- ¹ The SOUTA function is not available on the device. Do not select 0b01 or 0b11 for the PA field.
- ² When configured as PCSC[5], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-56. SOUTA_PCSC[5]_GPIO[95] Pad Configuration Register (SIU_PCR95)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-51](#) lists the PA fields for SOUTA_PCSC[5]_GPIO[95].

Table 6-51. PCR95 PA Field Definition

PA Field	Pin Function
0b00	GPIO[95]
0b01	Invalid value
0b10	PCSC[5]
0b11	Invalid value

6.3.1.58 Pad Configuration Registers 96 (SIU_PCR96)

The SIU_PCR96 registers control the function, direction, and electrical attributes of PCSA[0]_PCSD[2]_GPIO[96]. This register allows selection of the PCSA[0], PCSD[2] and GPIO functions.

¹ The PCSA[0] function is not available on this device. Do not select 0b01 or 0b11 for the PA field.

² When configured as PCSD[2], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.

³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-57. PCSA[0]_PCSD[2]_GPIO[96] Pad Configuration Register (SIU_PCR96)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-52](#) lists the PA fields for PCSA[0]_PCSD[2]_GPIO[96].

Table 6-52. PCR96 PA Field Definition

PA Field	Pin Function
0b00	GPIO[96]
0b01	Invalid value
0b10	PCSD[2]
0b11	Invalid value

6.3.1.59 Pad Configuration Registers 97 (SIU_PCR97)

The SIU_PCR97 registers control the function, direction, and electrical attributes of PCSA[1]_PCSB[2]_GPIO[97]. This register allows selection of the PCSB[2] and GPIO functions.

- ¹ The PCSA[1] function is not available on the device. Do not select 0b01 or 0b11 for the PA field.
- ² When configured as PCSB[2], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-58. PCSA[1]_PCSB[2]_GPIO[97] Pad Configuration Register (SIU_PCR97)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-53](#) lists the PA fields for PCSA[1]_PCSB[2]_GPIO[97].

Table 6-53. PCR97 PA Field Definition

PA Field	Pin Function
0b00	GPIO[97]
0b01	Invalid value
0b10	PCSB[2]
0b11	Invalid value

6.3.1.60 Pad Configuration Register 98 (SIU_PCR98)

The SIU_PCR98 register controls the function, direction, and electrical attributes of PCSA[2]_SCKD_GPIO[98]. This register allows selection of the PCSA[2],SCKD, and GPIO functions.

- ¹ The PCSA[2] function is not available on the device. Do not select 0b01 or 0b11 for the PA field.
- ² When configured as SCKD, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-59. PCSA[2]_SCKD_GPIO[98] Pad Configuration Register (SIU_PCR98)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-54](#) lists the PA fields for PCSA[2]_SCKD_GPIO[98].

Table 6-54. PCR98 PA Field Definition

PA Field	Pin Function
0b00	GPIO[98]
0b01	Invalid value
0b10	SCKD
0b11	Invalid value

6.3.1.61 Pad Configuration Register 99 (SIU_PCR99)

The SIU_PCR99 register controls the function, direction, and electrical attributes of PCSA[3]_SIND_GPIO[99]. This register allows selection of the PCSA[3], SIND and GPIO functions.

Address: Base + 0x0106 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA ¹		OBE ²	IBE ³	0	0	ODE	HYS	SRC		WPE	WPS
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

- ¹ The PCSA[3] function is not available on the device. Do not select 0b01 or 0b11 for the PA field.
- ² When configured as SIND, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-60. PCSA[3]_SIND_GPIO[99] Pad Configuration Register (SIU_PCR99)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-55](#) lists the PA fields for PCSA[3]_SIND_GPIO[99].

Table 6-55. PCR99 PA Field Definition

PA Field	Pin Function
0b00	GPIO[99]
0b01	Invalid value
0b10	SIND
0b11	Invalid value

6.3.1.62 Pad Configuration Register 100 (SIU_PCR100)

The SIU_PCR100 register controls the function, direction, and electrical attributes of PCSA[4]_SOUTD_GPIO[100]. This register allows selection of the SOUTD, and GPIO functions.

- ¹ The PCSA[4] function is not available on the device. Do not select 0b01 or 0b11 for the PA field.
- ² When configured as SOUTD, the OBE bit has no effect. When configured as GPDO, set the OBE to 1.
- ³ When SOUTD is configured for slave operation, set the IBE bit to 1. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-61. PCSA[4]_SOUTD_GPIO[100] Pad Configuration Register (SIU_PCR100)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-56](#) lists the PA fields for PCSA[4]_SOUTD_GPIO[100].

Table 6-56. PCR100 PA Field Definition

PA Field	Pin Function
0b00	GPIO[100]
0b01	Invalid value
0b10	SOUTD
0b11	Invalid value

6.3.1.63 Pad Configuration Registers 101 (SIU_PCR101)

The SIU_PCR101 register controls the function, direction, and electrical attributes of PCSA[5]_PCSB[3]_GPIO[101]. This register allows selection of the PCSB[3] and GPIO functions.

- ¹ The PCSA[5] function is not available on the device. Do not select 0b01 or 0b11 for the PA field.
- ² When configured as PCSB[3], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-62. PCSA[5]_PCSB[3]_GPIO[101] Pad Configuration Register (SIU_PCR101)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-57](#) lists the PA fields for PCSA[5]_PCSB[3]_GPIO[101].

Table 6-57. PCR101 PA Field Definition

PA Field	Pin Function
0b00	GPIO[101]
0b01	Invalid value
0b10	PCSB[3]
0b11	Invalid value

6.3.1.64 Pad Configuration Register 102 (SIU_PCR102)

The SIU_PCR102 register controls the function, direction, and electrical attributes of SCKB_PCSC[1]_GPIO[102].

¹ When configured as SCKB or PCSC[1], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.

² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-63. SCKB_PCSC[1]_GPIO[102] Pad Configuration Register (SIU_PCR102)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-58](#) lists the PA fields for SCKB_PCSC[1]_GPIO[102].

Table 6-58. PCR102 PA Field Definition

PA Field	Pin Function
0b00	GPIO[102]
0b01	SCKB
0b10	PCSC[1]
0b11	SCKB

6.3.1.65 Pad Configuration Register 103 (SIU_PCR103)

The SIU_PCR103 register controls the function, direction, and electrical attributes of SINB_PCSC[2]_GPIO[103].

- ¹ When configured as SINB, clear the OBE bit to 0. When configured as PCSC[2], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-64. SINB_PCSC[2]_GPIO[103] Pad Configuration Register (SIU_PCR103)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-59](#) lists the PA fields for SINB_PCSC[2]_GPIO[103].

Table 6-59. PCR103 PA Field Definition

PA Field	Pin Function
0b00	GPIO[103]
0b01	SINB
0b10	PCSC[2]
0b11	SINB

6.3.1.66 Pad Configuration Register 104 (SIU_PCR104)

The SIU_PCR104 register controls the function, direction, and electrical attributes of SOUTB_PCSC[5]_GPIO[104].

- ¹ When configured as SOUTB or PCSC[5], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-65. SOUTB_PCSC[5]_GPIO[104] Pad Configuration Register (SIU_PCR104)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-60](#) lists the PA fields for SOUTB_PCSC[5]_GPIO[104].

Table 6-60. PCR104 PA Field Definition

PA Field	Pin Function
0b00	GPIO[104]
0b01	SOUTB
0b10	PCSC[5]
0b11	SOUTB

6.3.1.67 Pad Configuration Register 105 (SIU_PCR105)

The SIU_PCR105 register controls the function, direction, and electrical attributes of PCSB[0]_PCSD[2]_GPIO[105].

Address: Base + 0x0112 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA		OBE ¹	IBE ²	0	0	ODE	HYS	SRC		WPE	WPS
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

¹ When configured as PCSB[0], set the OBE bit to 1 for master operation, or clear to 0 for slave operation. When configured as PCSD[2], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.

² When configured as PCSB[0] in slave operation, set the IBE bit to 1. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-66. PCSB[0]_PCSD[2]_GPIO[105] Pad Configuration Register (SIU_PCR105)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-61](#) lists the PA fields for PCSB[0]_PCSD[2]_GPIO[105].

Table 6-61. PCR105 PA Field Definition

PA Field	Pin Function
0b00	GPIO[105]
0b01	PCSB[0]
0b10	PCSD[2]
0b11	PCSB[0]

6.3.1.68 Pad Configuration Register 106 (SIU_PCR106)

The SIU_PCR106 register controls the function, direction, and electrical attributes of PCSB[1]_PCSD[0]_GPIO[106].

- ¹ When configured as PCSD[0], set the OBE bit to 1 for master operation, or clear to 0 for slave operation. When configured as PCSB[1], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When configured as PCSD[0] in slave operation, set the IBE bit to 1. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-67. PCSB[1]_PCSD[0]_GPIO[106] Pad Configuration Register (SIU_PCR106)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-62](#) lists the PA fields for PCSB[1]_PCSD[0]_GPIO[106].

Table 6-62. PCR106 PA Field Definition

PA Field	Pin Function
0b00	GPIO[106]
0b01	PCSB[1]
0b10	PCSD[0]
0b11	PCSB[1]

6.3.1.69 Pad Configuration Register 107 (SIU_PCR107)

The SIU_PCR107 register controls the function, direction, and electrical attributes of PCSB[2]_SOUTC_GPIO[107].

- ¹ When configured as PCSB[2] or SOUTC, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-68. PCSB[2]_SOUTC_GPIO[107] Pad Configuration Register (SIU_PCR107)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-63](#) lists the PA fields for PCSB[2]_SOUTC_GPIO[107].

Table 6-63. PCR107 PA Field Definition

PA Field	Pin Function
0b00	GPIO[107]
0b01	PCSB[2]
0b10	SOUTC
0b11	PCSB[2]

6.3.1.70 Pad Configuration Register 108 (SIU_PCR108)

The SIU_PCR108 register controls the function, direction, and electrical attributes of PCSB[3]_SINC_GPIO[108].

- ¹ When configured as PCSB[3] or SINC, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-69. PCSB[3]_SINC_GPIO[108] Pad Configuration Register (SIU_PCR108)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-64](#) lists the PA fields for PCSB[3]_SINC_GPIO[108].

Table 6-64. PCR108 PA Field Definition

PA Field	Pin Function
0b00	GPIO[108]
0b01	PCSB[3]
0b10	SINC
0b11	PCSB[3]

6.3.1.71 Pad Configuration Register 109 (SIU_PCR109)

The SIU_PCR109 register controls the function, direction, and electrical attributes of PCSB[4]_SCKC_GPIO[109].

- ¹ When configured as PCSB[4] or SCKC, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-70. PCSB[4]_SCKC_GPIO[109] Pad Configuration Register (SIU_PCR109)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-65](#) lists the PA fields for PCSB[4]_SCKC_GPIO[109].

Table 6-65. PCR109 PA Field Definition

PA Field	Pin Function
0b00	GPIO[109]
0b01	PCSB[4]
0b10	SCKC
0b11	PCSB[4]

6.3.1.72 Pad Configuration Register 110 (SIU_PCR110)

The SIU_PCR110 register controls the function, direction, and electrical attributes of PCSB[5]_PCSC[0]_GPIO[110].

- ¹ When configured as PCSB[5], the OBE bit has no effect. When configured as PCSC[0], set the OBE bit to 1 for master operation, or clear to 0 for slave operation. When configured as GPDO, set the OBE bit to 1.
- ² When configured as PCSC[0] in slave operation, set the IBE bit to 1. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-71. PCSB[5]_PCSC[0]_GPIO[110] Pad Configuration Register (SIU_PCR110)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-66](#) lists the PA fields for PCSB[5]_PCSC[0]_GPIO[110].

Table 6-66. PCR110 PA Field Definition

PA Field	Pin Function
0b00	GPIO[110]
0b01	PCSB[5]
0b10	PCSC[0]
0b11	PCSB[5]

6.3.1.73 Pad Configuration Registers 111–112 (SIU_PCR111–SIU_PCR112)

The SIU_PCR111–SIU_PCR112 registers control the function, direction, and electrical attributes of ETRIG[0:1]_GPIO[111:112].

Address: Base + 0x011E through Base + 0x0120

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	PA ¹	OBE ²	IBE ³	0	0	ODE	HYS	SRC		WPE	WPS
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

¹ The ETRIG[0:1] function is not available on the MPC5565. Do not select 0b1 for the PA field.

² When configured as GPDO, set the OBE bit to 1.

³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-72. ETRIG[0:1]_GPIO[111:112] Pad Configuration Register (SIU_PCR111–SIU_PCR112)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-67](#) lists the PA fields for ETRIG[0:1]_GPIO[111:112].

Table 6-67. PCR111–PCR112 PA Field Definition

PA Field	Pin Function
0b0	GPIO[111:112]
0b1	ETRIG[0:1]

6.3.1.74 Pad Configuration Register 113 (SIU_PCR113)

The SIU_PCR113 register controls the function, direction, and electrical attributes of TCRCLKA_̄IRQ[7]_GPIO[113].

- ¹ When configured as TCRCLKA or ̄IRQ[7], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-73. TCRCLKA_̄IRQ[7]_GPIO[113] Pad Configuration Register (SIU_PCR113)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-68](#) lists the PA fields for TCRCLKA_̄IRQ[7]_GPIO[113].

Table 6-68. PCR113 PA Field Definition

PA Field	Pin Function
0b00	GPIO[113]
0b01	TCRCLKA
0b10	̄IRQ[7]
0b11	TCRCLKA

6.3.1.75 Pad Configuration Register 114–117 (SIU_PCR114–SIU_PCR117)

The SIU_PCR114–SIU_PCR117 registers control the function, direction, and electrical attributes of ETPUA[0:3]_ETPUA[12:15]_GPIO[114:117]. Only the output channels of ETPUA[12:15] are connected. Both the input and output channels of ETPUA[0:3] are connected.

- ¹ The OBE bit must be set to 1 for ETPUA[0:3], and GPIO[114:117] when configured as outputs. When configured as ETPUA[12:15], the OBE bit has no effect.
- ² The IBE bit must be set to 1 for ETPUA[0:3] or GPIO[114:117] when configured as inputs. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register.
- ³ The weak pullup/down selection at reset for the ETPUA[0:3] pin is determined by the WKPCFG pin.

Figure 6-74. ETPUA[0:3]_ETPUA[12:15]_GPIO[114:117] Pad Configuration Register (SIU_PCR114–SIU_PCR117)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-69](#) lists the PA fields for ETPUA[0:3]_ETPUA[12:15]_GPIO[114:117].

Table 6-69. PCR114–PCR117 PA Field Definition

PA Field	Pin Function
0b00	GPIO[114:117]
0b01	ETPUA[0:3]
0b10	ETPUA[12:15]
0b11	ETPUA[0:3]

6.3.1.76 Pad Configuration Register 118 (SIU_PCR118)

The SIU_PCR118 registers control the function, direction, and electrical attributes of ETPUA[4]_ETPUA[16]_GPIO[118]. Only the output channel of ETPUA[16] is connected. Both the input and output channels of ETPUA[4] are connected.

Address: Base + 0x012C

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA	OBE ¹	IBE ²	0	0	ODE	HYS	SRC	WPE	WPS	U ³	
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	U ³

¹ The OBE bit must be set to 1 for ETPUA[4], ETPUA[16] and GPIO[118] when configured as outputs. When configured as ETPUA[16] the OBE bit has no effect.

² The IBE bit must be set to 1 for ETPUA[4], ETPUA[16] and GPIO[118] when configured as inputs. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register.

³ The weak pullup/down selection at reset for the ETPUA[16] and ETPUA[4], signals is determined by the WKPCFG pin.

Figure 6-75. ETPUA[4]_ETPUA[16]_GPIO[118] Pad Configuration Register (SIU_PCR118)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-70](#) lists the PA fields for ETPUA[4]_ETPUA[16]_GPIO[118].

Table 6-70. PCR118 PA Field Definition

PA Field	Pin Function
0b00	GPIO[118]
0b01	ETPUA[4]
0b10	ETPUA[16]
0b11	ETPUA[4]

6.3.1.77 Pad Configuration Register 119 (SIU_PCR119)

The SIU_PCR119 registers control the function, direction, and electrical attributes of ETPUA[5]_ETPUA[17]_GPIO[119]. Only the output channels of ETPUA[17] are connected. Both the input and output channels of ETPUA[5] are connected.

- ¹ When ETPUA[5], or GPIO[119] are configured as outputs, set the OBE bit to 1. When configured as ETPUA[17], the OBE bit has no effect.
- ² The IBE bit must be set to one for ETPUA[5], ETPUA[17], and GPIO[119] when configured as inputs. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register.
- ³ The weak pullup/down value at reset for ETPUA[5] and ETPUA[17], is determined by WKPCFG.

Figure 6-76. ETPUA[5]_ETPUA[17]_GPIO[119] Pad Configuration Register (SIU_PCR119)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-71](#) lists the PA fields for ETPUA[5]_ETPUA[17]_GPIO[119].

Table 6-71. PCR119 PA Field Definition

PA Field	Pin Function
0b00	GPIO[119]
0b01	ETPUA[5]
0b10	ETPUA[17]
0b11	ETPUA[5]

6.3.1.78 Pad Configuration Register 120 (SIU_PCR120)

The SIU_PCR120 register controls the function, direction, and electrical attributes of ETPUA[6]_ETPUA[18]_GPIO[120]. Only the output channels of ETPUA[18] are connected. Both the input and output channels of ETPUA[6] are connected.

- ¹ The OBE bit must be set to one for ETPUA[6] and GPIO[120] when configured as outputs. When configured as ETPUA[18], the OBE bit has no effect.
- ² The IBE bit must be set to 1 for ETPUA[6], ETPUA[18], and GPIO[120] when configured as inputs. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register.
- ³ The weak pullup/down selection at reset for the ETPUA[6], ETPUA[18], signals is determined by WKPCFG.

Figure 6-77. ETPUA[6]_ETPUA[18]_GPIO[120] Pad Configuration Register (SIU_PCR120)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-72](#) lists the PA fields for ETPUA[6]_ETPUA[18]_GPIO[120].

Table 6-72. PCR120 PA Field Definition

PA Field	Pin Function
0b00	GPIO[120]
0b01	ETPUA[6]
0b10	ETPUA[18]
0b11	ETPUA[6]

6.3.1.79 Pad Configuration Register 121 (SIU_PCR121)

The SIU_PCR121 register controls the function, direction, and electrical attributes of ETPUA[7]_ETPUA[19]_GPIO[121]. Only the output channel of ETPUA[19] is connected. Both the input and output channels of ETPUA[7] are connected.

Address: Base + 0x0132

Access: R/W

- ¹ The OBE bit must be set to 1 for ETPUA[7] and GPIO[121] when configured as outputs. When configured as ETPUA[19], the OBE bit has no effect.
- ² The IBE bit must be set to 1 for ETPUA[7], ETPUA[19], and GPIO[121] when configured as inputs. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPD1 register.
- ³ The weak pullup/down value at reset for ETPUA[7] and ETPUA[19] is determined by WKPCFG.

Figure 6-78. ETPUA[7]_ETPUA[19]_GPIO[121] Pad Configuration Register (SIU_PCR121)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-73](#) lists the PA fields for ETPUA[7]_ETPUA[19]_GPIO[121].

Table 6-73. PCR121 PA Field Definition

PA Field	Pin Function
0b00	GPIO[121]
0b01	ETPUA[7]
0b10	ETPUA[19]
0b11	ETPUA[7]

6.3.1.80 Pad Configuration Registers 122–124 (SIU_PCR122–SIU_PCR124)

The SIU_PCR122–SIU_PCR124 registers control the function, direction, and electrical attributes of ETPUA[8:10]_ETPUA[20:22]_GPIO[122:124]. The ETPUA[20:22] output channels only are connected. The ETPUA[8:10] input and output channels are connected.

- ¹ The OBE bit must be set to 1 for ETPUA[8:10], or GPIO[122:124] when configured as outputs. When configured as ETPUA[20], the OBE bit has no effect.
- ² The IBE bit must be set to 1 for ETPUA[8:10] or GPIO[122:124] when configured as inputs. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register.
- ³ The weak pullup/down value at reset for ETPUA[8:10] pin is determined by WKPCFG.

Figure 6-79. ETPUA[8:10]_ETPUA[20:22]_GPIO[122:124] Pad Configuration Register (SIU_PCR122–SIU_PCR124)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-74](#) lists the PA fields for ETPUA[8:10]_ETPUA[20:22]_GPIO[122:124].

Table 6-74. PCR122–124 PA Field Definition

PA Field	Pin Function
0b00	GPIO[122:124]
0b01	ETPUA[8:10]
0b10	ETPUA[20:22]
0b11	ETPUA[8:10]

6.3.1.81 Pad Configuration Register 125 (SIU_PCR125)

The SIU_PCR125 register controls the function, direction, and electrical attributes of ETPUA[11]_ETPUA[23]_GPIO[125]. Only the output channels of ETPUA[23] are connected. Both the input and output channels of ETPUA[11] are connected.

- ¹ The OBE bit must be set to 1 for ETPUA[11] or GPIO[125] when configured as outputs. When configured as ETPUA[23], the OBE bit has no effect.
- ² The IBE bit must be set to 1 for ETPUA[11] or GPIO[125] when configured as inputs. When the pad is configured as an output, setting the IBE bit to 1 allows the pin state to be reflected in the corresponding GPDI register.
- ³ The weak pullup/down selection at reset for the ETPUA[11] pin is determined by the WKPCFG pin.

Figure 6-80. ETPUA[11]_ETPUA[23]_GPIO[125] Pad Configuration Register (SIU_PCR125)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-75](#) lists the PA fields for ETPUA[11]_ETPUA[23]_GPIO[125].

Table 6-75. PCR125 PA Field Definition

PA Field	Pin Function
0b00	GPIO[125]
0b01	ETPUA[11]
0b10	ETPUA[23]
0b11	ETPUA[11]

6.3.1.82 Pad Configuration Register 126 (SIU_PCR126)

The SIU_PCR126 register controls the function, direction, and electrical attributes of ETPUA[12]_PCSB[1]_GPIO[126].

- ¹ When configured as PCSB[1], the OBE bit has no effect. The OBE bit must be set to 1 for ETPUA[12] or GPIO[126] when configured as outputs.
- ² The IBE bit must be set to 1 for ETPUA[12] or GPIO[126] when configured as inputs. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register.
- ³ The weak pullup/down selection at reset for the ETPUA[12] and PCSB[1] pin is determined by the WKPCFG pin.

Figure 6-81. ETPUA[12]_PCSB[1]_GPIO[126] Pad Configuration Register (SIU_PCR126)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-76](#) lists the PA fields for ETPUA[12]_PCSB[1]_GPIO[126].

Table 6-76. PCR126 PA Field Definition

PA Field	Pin Function
0b00	GPIO[126]
0b01	ETPUA[12]
0b10	PCSB[1]
0b11	ETPUA[12]

6.3.1.83 Pad Configuration Registers 127–129 (SIU_PCR127–SIU_PCR129)

The SIU_PCR127–SIU_PCR129 registers control the function, direction, and electrical attributes of ETPUA[13:15]_PCSB[3:5]_GPIO[127:129].

- ¹ When configured as PCSB[3:5], the OBE bit has no effect. The OBE bit must be set to 1 for ETPUA[13:15] or GPIO[127:129] when configured as outputs.
- ² The IBE bit must be set to 1 for ETPUA[13:15], PCSB[3:5], or GPIO[127:129] when configured as inputs. When configured as output, set the IBE bit to 1 to show the pin state in the GPDI register.
- ³ The weak pullup/down selection at reset for the ETPUA[13:15], and PCSB[3:5] pins is determined by the WKPCFG pin.

**Figure 6-82. ETPUA[13:15]_PCSB[3:5]_GPIO[127:129]
Pad Configuration Register (SIU_PCR127–SIU_PCR129)**

Refer to [Table 6-19](#) for bit field definitions. [Table 6-77](#) lists the PA fields for ETPUA[13:15]_PCSB[3:5]_GPIO[127:129].

Table 6-77. PCR127–129 PA Field Definition

0b00	GPIO[127:129]
0b01	ETPUA[13:15]
0b10	PCSB[3:5]
0b11	ETPUA[13:15]

6.3.1.84 Pad Configuration Register 130–133 (SIU_PCR130–SIU_PCR133)

The SIU_PCR130–SIU_PCR133 registers control the function, direction, and electrical attributes of ETPUA[16:19]_PCSD[1:4]_GPIO[130:133].

- ¹ When configured as PCSD[1:4], the OBE bit has no effect. Set the OBE bit to 1 for ETPUA[16:19] or GPIO[130:133] when configured as outputs.
- ² The IBE bit must be set to 1 for ETPUA[16:19] or GPIO[130:133] when configured as inputs. When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register.
- ³ The weak pullup/down selection at reset for the ETPUA[16:19] pin is determined by the WKPCFG pin.

**Figure 6-83. ETPUA[16:19]_PCSD[1:4]_GPIO[130:133]
Pad Configuration Register (SIU_PCR130–SIU_PCR133)**

Refer to [Table 6-19](#) for bit field definitions. [Table 6-78](#) lists the PA fields for ETPUA[16:19]_PCSD[1:4]_GPIO[130:133].

Table 6-78. PCR130–133 PA Field Definition

PA Field	Pin Function
0b00	GPIO[130:133]
0b01	ETPUA[16:19]
0b10	PCSD[1:4]
0b11	ETPUA[16:19]

6.3.1.85 Pad Configuration Register 134 (SIU_PCR134)

The SIU_PCR134 register controls the function, direction, and electrical attributes of ETPUA[20]_IRQ[8]_GPIO[134]. Both the input and output channels of ETPUA[20] are connected to pins.

- ¹ When configured as $\overline{\text{IRQ}}[8]$, the OBE bit has no effect. The OBE bit must be set to 1 for ETPUA[20] or GPIO[134] when configured as output.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPD1 register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for ETPUA[20] or GPIO[134] when configured as input.
- ³ The weak pullup/down selection at reset for the ETPUA[20] pin is determined by the WKPCFG pin.

Figure 6-84. ETPUA[20]_IRQ[8]_GPIO[134] Pad Configuration Register (SIU_PCR134)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-79](#) lists the PA fields for ETPUA[20]_IRQ[8]_GPIO[134].

Table 6-79. PCR134 PA Field Definition

PA Field	Pin Function
0b00	GPIO[134]
0b01	ETPUA[20]
0b10	$\overline{\text{IRQ}}[8]$
0b11	ETPUA[20]

6.3.1.86 Pad Configuration Register 135 (SIU_PCR135)

The SIU_PCR135 register controls the function, direction, and electrical attributes of ETPUA[21]_IRQ[9]_GPIO[135]. Both the input and output channels of ETPUA[21] are connected.

- ¹ When configured as IRQ[9], the OBE bit has no effect. The OBE bit must be set to one for ETPUA[21] or GPIO[135] when configured as outputs.
- ² When the pad is configured as an output, setting the IBE bit to 1 allows the pin state to be reflected in the corresponding GPDI register. Setting the IBE bit to zero reduces power consumption. The IBE bit must be set to one for ETPUA[21] or GPIO[135] when configured as inputs.
- ³ The weak pullup/down selection at reset for the ETPUA[21] pin is determined by the WKPCFG pin.

Figure 6-85. ETPUA[21]_IRQ[9]_GPIO[135] Pad Configuration Register (SIU_PCR135)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-80](#) lists the PA fields for ETPUA[21]_IRQ[9]_GPIO[135].

Table 6-80. PCR135 PA Field Definition

PA Field	Pin Function
0b00	GPIO[135]
0b01	ETPUA[21]
0b10	IRQ[9]
0b11	ETPUA[21]

6.3.1.87 Pad Configuration Register 136 (SIU_PCR136)

The SIU_PCR136 register controls the function, direction, and electrical attributes of ETPUA[22]_IRQ[10]_GPIO[136]. Both the input and output channels of ETPUA[22] are connected.

- ¹ When configured as IRQ[10], the OBE bit has no effect. The OBE bit must be set to 1 for ETPUA[22] or GPIO[136] when configured as output.
- ² When the pad is configured as an output, setting the IBE bit to 1 allows the pin state to be reflected in the corresponding GPDI register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for ETPUA[22] or GPIO[136] when configured as input.
- ³ The weak pullup/down selection at reset for the ETPUA[22] pin is determined by the WKPCFG pin.

Figure 6-86. ETPUA[22]_IRQ[10]_GPIO[136] Pad Configuration Register (SIU_PCR136)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-81](#) lists the PA fields for ETPUA[22]_IRQ[10]_GPIO[136].

Table 6-81. PCR136 PA Field Definition

PA Field	Pin Function
0b00	GPIO[136]
0b01	ETPUA[22]
0b10	IRQ[10]
0b11	ETPUA[22]

6.3.1.88 Pad Configuration Register 137 (SIU_PCR137)

The SIU_PCR137 register controls the function, direction, and electrical attributes of ETPUA[23]_IRQ[11]_GPIO[137]. Both the input and output channels of ETPUA[23] are connected.

Address: Base + 0x0152

Access: R/W

RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	U ³

¹ When configured as PCSC[4], the OBE bit has no effect. When configured as ETPUA[31] output or GPDO, set the OBE bit 1.

² When the pad is configured as an output, set the IBE bit to 1 show the pin state in the corresponding GPDI register. Clear the IBE bit to 0 reduces power consumption. Set the IBE bit to 1 for ETPUA or GPIO when configured as input.

³ The weak pullup/down selection at reset for the ETPUA[31] and PCSC[4] pin is determined by the WKPCFG pin.

Figure 6-90. ETPUA[31]_PCSC[4]_GPIO[145] Pad Configuration Register (SIU_PCR145)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-85](#) lists the PA fields for ETPUA[31]_PCSC[4]_GPIO[145].

Table 6-85. PCR145 PA Field Definition (continued)

PA Field	Pin Function
0b00	GPIO[145]
0b01	ETPUA[31]
0b10	PCSC[4]
0b11	ETPUA[31]

6.3.1.92 Pad Configuration Registers 146–178 (SIU_PCR146–SIU_PCR178)

The SIU_PCR146–SIU_PCR178 registers are not implemented in this device.

6.3.1.93 Pad Configuration Register 179–188 (SIU_PCR179–SIU_PCR188)

The SIU_PCR179–SIU_PCR188 registers control the function, direction, and electrical attributes of EMIOS[0:9]_ETPUA[0:9]_GPIO[179:188]. The input and output functions of EMIOS[0:9] are connected. Only the output channels of ETPUA[0:9] are connected.

- ¹ The OBE bit must be set to 1 for EMIOS[0:9] or GPIO[179:188] when configured as output.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for EMIOS[0:9] or GPIO[179:188] when configured as inputs.
- ³ The weak pullup/down selection at reset for the EMIOS[0:9] pins is determined by the WKPCFG pin.

Figure 6-91. EMIOS[0:9]_ETPUA[0:9]_GPIO[179:188] Pad Configuration Register (SIU_PCR179–SIU_PCR188)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-86](#) lists the PA fields for EMIOS[0:9]_ETPUA[0:9]_GPIO[179:188].

Table 6-86. PCR179–188 PA Field Definition

PA Field	Pin Function

6.3.1.94 Pad Configuration Register 189–190 (SIU_PCR189–SIU_PCR190)

The SIU_PCR189–SIU_PCR190 registers control the function, direction, and electrical attributes of EMIOS[10:11]_PCSD[3:4]_GPIO[189:190]. Both the input and output functions of EMIOS[10:11] are connected.

- ¹ The OBE bit must be set to 1 for EMIOS[10:11] or GPIO[189:190] when configured as output.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for EMIOS[10:11] or GPIO[189:190] when configured as input.
- ³ The weak pullup/down selection at reset for the EMIOS[10:11] pins is determined by the WKPCFG pin.

Figure 6-92. EMIOS[10:11]_PCSD[3:4]_GPIO[189:190] Pad Configuration Register (SIU_PCR189–SIU_PCR190)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-87](#) lists the PA fields for EMIOS[10:11]_PCSD[3:4]_GPIO[189:190].

EMIOS[10:11]

6.3.1.95 Pad Configuration Register 191 (SIU_PCR191)

The SIU_PCR191 register controls the function, direction, and electrical attributes of EMIOS[12]_SOUTC_GPIO[191]. Only the output of EMIOS[12] is connected.

- ¹ The OBE bit must be set to 1 for GPIO[191] when configured as an output.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for GPIO[191] when configured as an input.
- ³ The weak pullup/down selection at reset for the EMIOS[12] pin is determined by the WKPCFG pin.

Figure 6-93. EMIOS[12]_SOUTC_GPIO[191] Pad Configuration Register (SIU_PCR191)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-88](#) lists the PA fields for EMIOS[12]_SOUTC_GPIO[191].

Table 6-88. PCR191 PA Field Definition

PA Field	Pin Function
0b00	GPIO[191]
0b01	EMIOS[12]
0b10	SOUTC
0b11	EMIOS[12]

6.3.1.96 Pad Configuration Register 192 (SIU_PCR192)

The SIU_PCR192 register controls the function, direction, and electrical attributes of EMIOS[13]_SOUTD_GPIO[192]. Only the output of EMIOS[13] is connected.

- ¹ The OBE bit must be set to 1 for GPIO[192] when configured as an output.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPD1 register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for GPIO[192] when configured as an input.
- ³ The weak pullup/down selection at reset for the EMIOS[13] pin is determined by the WKPCFG pin.

Figure 6-94. EMIOS[13]_SOUTD_GPIO[192] Pad Configuration Register (SIU_PCR192)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-89](#) lists the PA fields for EMIOS[13]_SOUTD_GPIO[192].

Table 6-89. PCR192 PA Field Definition

PA Field	Pin Function
0b00	GPIO[192]
0b01	EMIOS[13]
0b10	SOUTD
0b11	EMIOS[13]

6.3.1.97 Pad Configuration Register 193 (SIU_PCR193)

The SIU_PCR193 register controls the function, direction, and electrical attributes of EMIOS[14]_IRQ[0]_GPIO[193]. The input and output functions for EMIOS[14] are both connected.

- ¹ The OBE bit must be set to 1 for GPIO[193] when configured as output.
- ² When the pad is configured as output, set the IBE bit to 1 to show the pin state in the GPD1 register. Clear the IBE bit to 0 to reduce power consumption. When GPIO[193] is configured as input, set the IBE bit 1.
- ³ The weak pullup/down selection at reset for the EMIOS[14] pin is determined by the WKPCFG pin.

Figure 6-95. EMIOS[14]_IRQ[0]_GPIO[193] Pad Configuration Register (SIU_PCR193)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-90](#) lists the PA fields for EMIOS[14]_IRQ[0]_GPIO[193].

Table 6-90. PCR193 PA Field Definition

PA Field	Pin Function
0b00	GPIO[193]
0b01	EMIOS[14]
0b10	IRQ[0]
0b11	EMIOS[14]

6.3.1.98 Pad Configuration Register 194 (SIU_PCR194)

The SIU_PCR194 register controls the function, direction, and electrical attributes of EMIOS[15]_IRQ[1]_GPIO[194]. Both input and output functions of EMIOS[15] are connected.

Address: Base + 0x01C2 through Base + 0x01C8

Access: R/W

- ¹ The OBE bit must be set to 1 for GPIO[194] when configured as output.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to one for GPIO[194] when configured as input.
- ³ The weak pullup/down selection at reset for the EMIOS[15] pin is determined by the WKPCFG pin.

Figure 6-96. EMIOS[15]_IRQ[1]_GPIO[194] Pad Configuration Register (SIU_PCR194)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-91](#) lists the PA fields for EMIOS[15]_IRQ[1]_GPIO[194].

Table 6-91. PCR194 PA Field Definition

PA Field	Pin Function
0b00	GPIO[194]
0b01	EMIOS[15]
0b10	IRQ[1]
0b11	EMIOS[15]

6.3.1.99 Pad Configuration Register 195 (SIU_PCR195)

The SIU_PCR195 register controls the function, direction, and electrical attributes of EMIOS[16]_GPIO[195]. Both the input and output functions of EMIOS[16] are connected.

- ¹ The PA function using the 0b10 value is disabled on this device.
- ² The OBE bit must be set to 1 for EMIOS[16] or GPIO[195] when configured as output.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPD1 register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for EMIOS[16] or GPIO[195] when configured as input.
- ⁴ The weak pullup/down selection at reset for the EMIOS[16] pin is determined by the WKPCFG pin.

Figure 6-97. EMIOS[16]_GPIO[195] Pad Configuration Register (SIU_PCR195)

6.3.1.100 Pad Configuration Register 196 (SIU_PCR196)

The SIU_PCR196 register controls the function, direction, and electrical attributes of EMIOS[17]_GPIO[196]. Both the input and output functions of EMIOS[17] are connected.

- ¹ The PA function using the 0b10 value is disabled on this device.
- ² The OBE bit must be set to one for EMIOS[17] and GPIO[196] when configured as outputs.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPD1 register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for EMIOS[17] or GPIO[196] when configured as input.
- ⁴ The weak pullup/down selection at reset for the EMIOS[17] pin is determined by the WKPCFG pin.

Figure 6-98. EMIOS[17]_GPIO[196] Pad Configuration Register (SIU_PCR196)

6.3.1.102 Pad Configuration Register 198 (SIU_PCR198)

The SIU_PCR198 register controls the function, direction, and electrical attributes of the EMIOS[19]_GPIO[198] pin. Both the input and output functions of EMIOS[19] are connected.

- ¹ The PA function using the 0b10 value is disabled on this device.
- ² The OBE bit must be set to 1 for EMIOS[19] and GPIO[198] when configured as output.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for EMIOS[19] or GPIO[198] when configured as input.
- ⁴ The weak pullup/down selection at reset for the EMIOS[19] pins is determined by the WKPCFG pin.

Figure 6-100. EMIOS[19]_GPIO[198] Pad Configuration Register (SIU_PCR198)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-95](#) lists the PA fields for EMIOS[19]_GPIO[198].

Table 6-95. PCR198 PA Field Definition

PA Field	Pin Function
0b00	GPIO[198]
0b01	EMIOS[19]
0b10	Invalid value
0b11	EMIOS[19]

6.3.1.103 Pad Configuration Registers 199–200 (SIU_PCR199–SIU_PCR200)

The SIU_PCR199–SIU_PCR200 registers control the function, direction, and electrical attributes of EMIOS[20:21]_GPIO[199:200]. Both the input and output functions of EMIOS[20:21] are connected.

- ¹ The PA function using the 0b10 value is disabled on this device.
- ² The OBE bit must be set to 1 for EMIOS[20:21] or GPIO[199:200] when configured as output.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for EMIOS[20:21] or GPIO[199:200] when configured as input.
- ⁴ The weak pullup/down selection at reset for the EMIOS[20:21] pin is determined by the WKPCFG pin.

Figure 6-101. EMIOS[20:21]_GPIO[199:200] Pad Configuration Register (SIU_PCR199–SIU_PCR200)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-96](#) lists the PA fields for EMIOS[20:21]_GPIO[199:200].

Table 6-96. PCR199–200 PA Field Definition

PA Field	Pin Function
0b00	GPIO[199:200]
0b01	EMIOS[20:21]
0b10	Invalid value
0b11	EMIOS[20:21]

6.3.1.104 Pad Configuration Register 201 (SIU_PCR201)

The SIU_PCR201 register controls the function, direction, and electrical attributes of EMIOS[22]_GPIO[201]. Both the input and output functions of EMIOS[22] are connected.

- ¹ The PA function using the 0b10 value is disabled on this device.
- ² The OBE bit must be set to 1 for EMIOS[22] or GPIO[201] when configured as output.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPD1 register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for EMIOS[22] or GPIO[201] when configured as input.
- ⁴ The weak pullup/down selection at reset for the EMIOS[22] pin is determined by the WKPCFG pin.

Figure 6-102. EMIOS[22]_GPIO[201] Pad Configuration Register (SIU_PCR201)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-97](#) lists the PA fields for EMIOS[22]_GPIO[201].

Table 6-97. PCR201 PA Field Definition

PA Field	Pin Function
0b00	GPIO[201]
0b01	EMIOS[22]
0b10	Invalid value
0b11	EMIOS[22]

6.3.1.105 Pad Configuration Register 202 (SIU_PCR202)

The SIU_PCR202 register controls the function, direction, and electrical attributes of EMIOS[23]_GPIO[202]. Both the input and output functions of EMIOS[23] are connected.

- ¹ The PA function using the 0b10 value is disabled on this device.
- ² The OBE bit must be set to 1 for EMIOS[23] or GPIO[202] when configured as output.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. The IBE bit must be set to 1 for EMIOS[23] or GPIO[202] when configured as input.
- ⁴ The weak pullup/down selection at reset for the EMIOS[23] pin is determined by the WKPCFG pin.

Figure 6-103. EMIOS[23]_GPIO[202] Pad Configuration Register (SIU_PCR202)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-98](#) lists the PA fields for EMIOS[23]_GPIO[202].

Table 6-98. PCR202 PA Field Definition

PA Field	Pin Function
0b00	GPIO[202]
0b01	EMIOS[23]
0b10	Invalid value
0b11	EMIOS[23]

6.3.1.106 Pad Configuration Registers 203–204 (SIU_PCR203–SIU_PCR204)

The SIU_PCR203–SIU_PCR204 registers control the function, direction, and electrical attributes of EMIOS[14:15]_GPIO[203:204]. Only the output functions of EMIOS[14:15] are connected.

These signals are named GPIO[203:204] because other balls are named EMIOS[14:15]. The primary function is EMIOS, however, they are configured out of reset for GPIO use. These signals are not affected by WKPCFG.

- ¹ When configured as EMIOS[14:15] the OBE bit has no effect. When GPIO[203:204] is configured as output, set the OBE bit to 1.
- ² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

Figure 6-104. EMIOS[14:15]_GPIO[203:204] Pad Configuration Registers (SIU_PCR203–SIU_PCR204)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-99](#) lists the PA fields for EMIO[14:15]_GPIO[203:204].

Table 6-99. PCR203–204 PA Field Definition

PA Field	Pin Function
0b0	GPIO[203:204]
0b1	EMIO[14:15]

6.3.1.107 Pad Configuration Register 205 (SIU_PCR205)

The SIU_PCR205 register controls the direction and electrical attributes of the GPIO[205] pin. This register is separate from the PCRs for GPIO[206:207] since GPIO[205] is a medium pad type with slew rate control and GPIO[206:207] are fast pad types with drive strength control. The PA bit is not implemented for this PCR because GPIO is the only pin function.

Address: Base + 0x01DA

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0	0	0	0	0	0	OBE ¹	IBE ²	0	0	ODE	HYS	SRC	WPE	WPS		
W																	
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

¹ When configured as GPDO, set the OBE bit to 1.

² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. When configured as GPDI, set the IBE bit to 1.

Figure 6-105. GPIO[205] Pad Configuration Registers (SIU_PCR205)

6.3.1.108 Pad Configuration Registers 206–207 (SIU_PCR206–SIU_PCR207)

The SIU_PCR206–SIU_PCR207 registers control the function, direction, and electrical attributes of GPIO[206:207]. These registers are separate from the PCR for GPIO[205] since GPIO[206:207] are fast pad types with drive strength control and GPIO[205] is a medium pad type with slew rate control. The PA bit is not implemented for these PCRs since GPIO is the only function.

NOTE

The GPIO[206:207] can trigger the ADCs. For ETRIG functionality, set these pins to GPIO, and then select the GPIO ADC trigger in the SIU_ETISR register. The input source for each SIN, SS, SCK, and trigger signal is individually specified in the DSPI input select register (SIU_DISR).

Refer to [Section 6.3.1.153](#), “eQADC Trigger Input Select Register (SIU_ETISR).”

System Integration Unit (SIU)

Address: Base + 0x01DC through Base + 0x01DE

Access: R/W

¹ When configured as GPDO, set the OBE bit to 1.

² When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. When configured as GPDI, set the IBE bit to 1.

Figure 6-106. GPIO[206:207] Pad Configuration Registers (SIU_PCR206–SIU_PCR207)

6.3.1.109 Pad Configuration Register 208 (SIU_PCR208)

The SIU_PCR208 register controls the function, direction, and electrical attributes of PLLCFG[0]_IRQ[4]_GPIO[208].

Address: Base + 0x01E0

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA ¹	OBE ²	IBE ³	0	0	ODE	HYS ⁴	SRC	WPE	WPS		
W																
RESET:	0	0	0	0	1	1	0	0	0	0	1	0	0	1	1	

¹ The PLLCFG[0] function applies only during reset when the \overline{RSTCFG} pin is asserted. Set the PA field to 0b10 for IRQ[4], or to 0b00 for GPIO[208].

² When configured as IRQ[4], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.

³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.

⁴ When configured as IRQ[4], set the HYS bit to 1.

Figure 6-107. PLLCFG[0]_IRQ[4]_GPIO[208] Pad Configuration Register (SIU_PCR208)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-100](#) lists the PA fields for PLLCFG[0]_IRQ[4]_GPIO[208].

Table 6-100. PCR208 PA Field Definition

0b00	GPIO[208]
0b01	PLLCFG[0]
0b10	$\overline{IRQ[4]}$
0b11	PLLCFG[0]

6.3.1.110 Pad Configuration Register 209 (SIU_PCR209)

The SIU_PCR209 register controls the function, direction, and electrical attributes of PLLCFG[1]_IRQ[5]_SOUTD_GPIO[209].

- ¹ The PLLCFG[1] function applies only during reset when the $\overline{\text{RSTCFG}}$ pin is asserted during reset. Set the PA field to 0b010 for $\overline{\text{IRQ}}[5]$, 0b100 for SOUTD, and 0b000 for GPIO[209].
- ² When configured as $\overline{\text{IRQ}}[5]$, the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ⁴ When configured as $\overline{\text{IRQ}}[5]$, set the HYS bit to 1.

Figure 6-108. PLLCFG[1]_IRQ[5]_SOUTD_GPIO[209] Pad Configuration Register (SIU_PCR209)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-101](#) lists the PA fields for PLLCFG[1]_IRQ[5]_SOUTD_GPIO[209].

Table 6-101. PCR209 PA Field Definition

PA Field	Pin Function
0b000	GPIO[209]
0b001	PLLCFG[1]
0b010	$\overline{\text{IRQ}}[5]$
0b011	PLLCFG[1]
0b100	SOUTD

6.3.1.111 Pad Configuration Register 210 (SIU_PCR210)

The SIU_PCR210 register controls the function, direction, and electrical attributes of $\overline{\text{RSTCFG}}$ _GPIO[210].

- ¹ $\overline{\text{RSTCFG}}$ function is only applicable during reset. The PA bit must be set to 0 for GPIO operation.
- ² When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. When configured as GPDI, set the IBE bit to 1.

Figure 6-109. $\overline{\text{RSTCFG}}$ _GPIO[210] Pad Configuration Register (SIU_PCR210)

6.3.1.112 Pad Configuration Registers 211–212 (SIU_PCR211–SIU_PCR212)

The SIU_PCR211–SIU_PCR212 registers control the function, direction, and electrical attributes of BOOTCFG[0:1]_IRQ[2:3]_GPIO[211:212].

- ¹ The BOOTCFG[0:1] function applies only during reset when the RSTCFG pin is asserted during reset. Set the PA field to 0b10 for IRQ[2:3], or to 0b00 for GPIO[211:212].
- ² When configured as IRQ[2:3], the OBE bit has no effect. When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the GPDI register. Clear the IBE bit to 0 to reduce power consumption. When configured as GPDI, set the IBE bit to 1.
- ⁴ When configured as IRQ[2:3], set the HYS bit to 1.

Figure 6-110. BOOTCFG[0:1]_IRQ[2:3]_GPIO[211:212] Pad Configuration Register (SIU_PCR211–SIU_PCR212)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-102](#) lists the PA fields for BOOTCFG[0:1]_IRQ[2:3]_GPIO[211:212].

Table 6-102. PCR211–212 PA Field Definition

PA Field	Pin Function
0b00	GPIO[211:212]
0b01	BOOTCFG[0:1]
0b10	IRQ[2:3]
0b11	BOOTCFG[0:1]

6.3.1.113 Pad Configuration Register 213 (SIU_PCR213)

The SIU_PCR213 register controls the function, direction, and electrical attributes of WKPCFG_GPIO[213].

- ¹ WKPCFG function is only applicable during reset. The PA bit must be cleared to 0 for GPIO operation.
- ² When configured as GPDO, set the OBE bit to 1.
- ³ When the pad is configured as an output, set the IBE bit to 1 to show the pin state in the corresponding GPDI register. When configured as GPDI, set the IBE bit to 1.

Figure 6-111. WKPCFG_GPIO[213] Pad Configuration Register (SIU_PCR213)

6.3.1.114 Pad Configuration Register 214 (SIU_PCR214)

The SIU_PCR214 register enables or disables ENGCLK and controls the drive strength. ENGCLK is enabled or disabled by setting or clearing the OBE bit. ENGCLK is enabled during reset.

Address: Base + 0x01EC Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	OBE	0	DSC		0	0	0	0	0	0
W																
RESET:	0	0	0	0	0	0	1	0	1	1	0	0	0	0	0	0

Figure 6-112. ENGLCK Pad Configuration Register (SIU_PCR214)

6.3.1.115 Pad Configuration Register 215 (SIU_PCR215)

The SIU_PCR215 register controls the function, direction, and electrical attributes of AN[12]_MA[0]_SDS.

Address: Base + 0x01EE Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	PA ^{1, 2}		0	0	0	0	ODE	0	SRC		0	0
W																
RESET:	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0

¹ Enable or disable input and output buffers based on the PA selection. Output buffers are disabled for the AN[12] function. Output buffers can be enabled only for MA[0] or SDS functions.

² To select the SDS function, set the PA field to 0b00.

Figure 6-113. AN[12]_MA[0]_SDS Pad Configuration Register (SIU_PCR215)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-103](#) lists the PA fields for AN[12]_MA[0]_SDS.

Table 6-103. PCR215 PA Field Definition

PA Field	Pin Function
0b00	SDS
0b01	Invalid value
0b10	MA[0]
0b11	AN[12]

6.3.1.116 Pad Configuration Register 216 (SIU_PCR216)

The SIU_PCR216 register controls the function, direction, and electrical attributes of AN[13]_MA[1]_SDO.

- ¹ Input and output buffers are enabled/disabled based on PA selection. Both input and output buffers are disabled for AN[13] function. Output buffers only can be enabled for MA[1] and SDO functions.
- ² To select the SDO function, set the PA field to 0b00.

Figure 6-114. AN[13]_MA[1]_SDO Pad Configuration Register (SIU_PCR216)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-104](#) lists the PA fields for AN[13]_MA[1]_SDO.

Table 6-104. PCR216 PA Field Definition

PA Field	Pin Function
0b00	SDO
0b01	Invalid value
0b10	MA[1]
0b11	AN[13]

6.3.1.117 Pad Configuration Register 217 (SIU_PCR217)

The SIU_PCR217 register controls the pin function, direction, and electrical attributes of AN[14]_MA[2]_SDI.

- ¹ Input and output buffers are enabled/disabled based on PA selection. Both input and output buffers are disabled for AN[14] function. Output buffers only can be enabled for MA[2] and SDI functions.
- ² To select the SDI function, set the PA field to 0b00.
- ³ Set the WPE bit to 0 when configured as analog input or MA[2], or set to 1 when configured as SDI.
- ⁴ Set the WPS bit to 1 when configured as SDI.

Figure 6-115. AN[14]_MA[2]_SDI Pad Configuration Register (SIU_PCR217)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-105](#) lists the PA fields for AN[14]_MA[2]_SDI.

Table 6-105. PCR217 PA Field Definition

PA Field	Pin Function
0b00	SDI
0b01	Invalid value
0b10	MA[2]
0b11	AN[14]

6.3.1.118 Pad Configuration Register 218 (SIU_PCR218)

The SIU_PCR218 register controls the function, direction, and electrical attributes of AN[15]_FCK.

Address: Base + 0x01F4 Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

6.3.1.150 Pad Configuration Register 298 (SIU_PCR298)

The SIU_PCR298 register controls the function, direction, and electrical attributes of CAL_ \overline{TS} .

Figure 6-146. CAL_ \overline{TS} Pad Configuration Registers (SIU_PCR298)

Refer to [Table 6-19](#) for bit field definitions. [Table 6-129](#) lists the PA fields for CAL_ \overline{TS} .

Table 6-129. PCR298 PA Field Definition

PA Field	Pin Function
0b0	Invalid value
0b1	CAL_ \overline{TS}

6.3.1.151 GPIO Pin Data Output Registers 0–213 (SIU_GPDO n)

The 8-bit SIU_GPDO n registers defined in [Figure 6-147](#) each specify the output data for the function assigned to the GPIO[n] pin. The n notation in the 178 SIU_GPDO n register names relate to the [n] in GPIO[n] signal name. For example, SIU_GPDO0 contains the PDO0 bit for \overline{CS} [0]_GPIO[0]; and

SIU_GPDO213 contains the PDO213 bit for WKPCFG_GPIO[213]. The address for a GPDO pin is the GPIO number plus an offset of SIU_BASE + 0x0600.

Software writes to the SIU_GPDO n registers to drive data out on the external pin. Each register drives one external pin, which allows independent control of the pin. Writes to the SIU_GPDO n registers have no effect if an input function is assigned to the pin by the pad configuration register.

If the direction of a GPIO signal changes from input to output, the SIU_GPDO n register value is automatically driven out to the external pin without a software update.

Writes to the SIU_GPDO n registers have no effect when a primary or alternate function is assigned.

Figure 6-147. General Purpose Data Output (GPDO) Registers 0–213 (SIU_GPDO n)

Table 6-130 describes the PDO n bit field in the general purpose data output registers:

Table 6-130. SIU_GPDO n Field Descriptions

Name	Description
PDO n	Pin data out. Stores the data to drive out the external GPIO. If the register is read, it returns the value written. 0 V_{OL} is driven on the external GPIO pin when the pin is configured as an output. 1 V_{OH} is driven on the external GPIO pin when the pin is configured as an output.

6.3.1.152 GPIO Pin Data Input Registers 0–213 (SIU_GPDI n)

The 8-bit read-only SIU_GPDI n registers defined in Figure 6-148 each specify the input state for the function assigned to the GPDI[n] pin. The n notation in the 178 SIU_GPDI n register names relate to the [n] in GPIO[n] signal name. For example, SIU_GPDI0 contains the PDI0 bit for CS[0]_GPIO[0]; and SIU_GPDI213 contains the PDI213 bit for WKPCFG_GPIO[213]. The GPDI address for a particular pin is the GPIO number plus an offset of SIU_BASE + 0x0800. Gaps exist in the memory where GPIO pins are not implemented in the package.

Software reads the SIU_GPDI n registers to get the input state of the external GPIO pin. Each GPDI register contains the input state of one external GPIO pin. If a GPDI register is configured as output, and the input buffer enable bit is set to one in the PCR register, the SIU_GPDI n register reflects the state of the output pin.

Figure 6-148. General Purpose Data Input (GPDI) Registers 0–213 (SIU_GPDI_n)

Table 6-131 describes the PDI_n bit field in the general purpose data input registers:

Table 6-131. SIU_GPDI_n Field Description

Name	Description
PDI _n	Pin data in. This bit reflects the input state on the external GPIO pin for the register. If PCR _n [IBE] = 1, then: 0 Signal on pin is less than or equal to V _{IL} . 1 Signal on pin is greater than or equal to V _{IH} .

6.3.1.153 eQADC Trigger Input Select Register (SIU_ETISR)

The SIU_ETISR defines the input sources for the eQADC trigger. The eQADC triggers numbered 0–5 are defined in TSEL 0–5 and correspond to CFIFOs 0–5. To determine the valid input pins a trigger activates, divide the DMA channel number by two, and consult Table 6-132. For example, DMA channel 2 is connected to eQADC CFIFO 1, therefore TSEL[1] can be triggered by eTPUA[31], eMIOS[11] or ETRIG[1]. To use a trigger, the TSEL must be initialized.

When an eQADC trigger is connected, the timer output is connected to the eQADC CFIFO trigger input. To trigger the eQADC, the timer output pin must change to the state that the eQADC recognizes as a trigger. Bear in mind there are rising or falling edges, and low or high gated trigger types, so it might be possible to have the eQADC trigger immediately if desired.

The following table lists the interconnections for the eQADC triggers:

Table 6-132. Trigger Interconnections

TSEL Field (Trigger Number)	eQADC CFIFO	eQADC DMA Channel	eTPUA Channel	eMIOS Channel	ETRIG Input	GPIO[206]: GPIO[207]
0	0	0	eTPUA[30]	eMIOS[10]	ETRIG[0]	GPIO[206]
1	1	2	eTPUA[31]	eMIOS[11]	ETRIG[1]	GPIO[207]
2	2	4	eTPUA[29]	eMIOS[15]	ETRIG[0]	GPIO[206]
3	3	6	eTPUA[28]	eMIOS[14]	ETRIG[1]	GPIO[207]
4	4	8	eTPUA[27]	eMIOS[13]	ETRIG[0]	GPIO[206]
5	5	10	eTPUA[26]	eMIOS[12]	ETRIG[1]	GPIO[207]

The following register shows the location of the eQADC trigger input select fields:

26–27	SSSELD [0:1]	DSPI D slave select input select. Specifies the source of the PCSD slave select input. 00 PCSB[1]_PCSD[0]_GPIO[106] pin 01 Invalid value 10 PCSB[0] (master) 11 PCSC[0] (master)
28–29	SCKSELD [0:1]	DSPI D clock input select. Specifies the source of the PCSD clock input in slave mode. 00 PCSA[2]_SCKD_GPIO[98] pin 01 Invalid value 10 SCKB (master) 11 SCKC (master)
30–31	TRIGSELD [0:1]	DSPI D trigger input select. Specifies the source of the PCSD trigger input for master or slave mode. 00 Invalid value 01 Invalid value 10 PCSB[4] 11 PCSC[4]

6.3.1.156 Chip Configuration Register (SIU_CCR)

The SIU_CCR controls the chip configuration for enabling and disabling Nexus and selecting the calibration bus signals on the external bus interface.

Address: Base + 0x0980

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	MATCH	DISNEX
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	X ¹
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	CSRE	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

¹ When system reset negates, the value in this bit depends on the censorship control word and the boot configuration bits.

Figure 6-152. Chip Configuration Register (SIU_CCR)

The following table describes the chip configuration fields:

Table 6-136. SIU_CCR Field Descriptions

Bits	Name	Description
0–13	—	Reserved
14	MATCH	Compare register match. Holds the value of the match input signal to the SIU. The match input is asserted if the values in the SIU_CARH/SIU_CARL and SIU_CBRH/SIU_CBRL are equal. The MATCH bit is reset by the synchronous reset signal. 0 The contents of SIU_CARH and SIU_CARL does not match the contents of SIU_CBRH and SIU_CBRL 1 The contents of SIU_CARH and SIU_CARL matches the contents of SIU_CBRH and SIU_CBRL
15	DISNEX	Disable Nexus. Holds the value of the Nexus disable input signal to the SIU. When system reset negates, the value in this bit depends on the censorship control word and the boot configuration bits. 0 Nexus disable input signal is negated. 1 Nexus disable input signal is asserted.
16–29	—	Reserved
30	CSRE	The CRSE bit enables the suppression of reflection from the EBI's calibration bus onto the non-calibration bus. The EBI drives some outputs to both the calibration and non-calibration busses. When CRSE is asserted, the values driven onto the calibration bus are not reflected onto the non-calibration bus pins. When CRSE is negated, the values driven onto the calibration bus are reflected onto the non-calibration bus. CRSE only enables reflection suppression for the non-calibration bus pins that do not have a negated state to which the pins return at the end of the access. CRSE does not enable reflection suppression for the non-calibration bus pins that have a negated state to which the pins return at the end of an access. Those reflections always are suppressed. Furthermore, the suppression of reflections from the non-calibration bus onto the calibration bus is not enabled by CRSE. Those reflections also always are suppressed. 0 Calibration reflection suppression is enabled. 1 Calibration reflection suppression is disabled.
31	Reserved	

6.3.1.157 External Clock Control Register (SIU_ECCR)

The SIU_ECCR controls the timing relationship between the system clock and the external clocks ENGCLK and CLKOUT. All bits and fields in the SIU_ECCR are read/write and are reset by the synchronous reset signal.

Address: Base + 0x0984

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15			
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0			
W

Figure 6-153. External Clock Control Register (SIU_ECCR)

The following table describes the external clock control fields:

Table 6-137. SIU_ECCR Field Descriptions

Bits	Name	Description
0–17	—	Reserved
18–23	ENGDIV [0:5]	<p>Engineering clock division factor. Specifies the frequency ratio between the system clock and ENGCLK. The ENGCLK frequency is divided from the system clock frequency according to the following equation:</p> $\text{Engineering clock frequency} = \frac{\text{System clock frequency}}{\text{ENGDIV} \times 2}$ <p>The maximum ENGCLK frequency is 66 MHz (132 MHz ÷ 2)</p> <p>Note: Clearing ENGDIV to 0 is the reset setting. Synchronization between ENGCLK and CLKOUT cannot be guaranteed when ENGDIV is 0.</p>
24–27	—	Reserved
28	EBTS	<p>External bus tap select. Changes the phase relationship between the system clock and CLKOUT. Changing the phase relationship so that CLKOUT is advanced in relation to the system clock increases the output hold time of the external bus signals to a non-zero value. It also increases the output delay times, increases the input hold times to non-zero values, and decreases the input setup times. Refer to the <i>Electrical Specifications</i> for how the EBTS bit affects the external bus timing.</p> <p>0 External bus signals have zero output hold times. 1 External bus signals have non-zero output hold times.</p> <p>Note: Do not change EBTS while an external bus transaction is in process.</p>

Table 6-137. SIU_ECCR Field Descriptions

Bits	Name	Description
29	—	Reserved
30–31	EBDF [0:1]	External bus division factor. Specifies the frequency ratio between the system clock and the external clock, CLKOUT. Do not change EBDF during an external bus access or while an access is pending. The CLKOUT frequency is divided from the system clock frequency according to the descriptions below. When operating in dual controller mode (1:1), set the divider to 0b01 (divide-by-2). 00 Invalid value 01 Divide by 2 10 Invalid value 11 Divide by 4

6.3.1.158 Compare A Register High (SIU_CARH)

The compare registers are not intended for general application use, but are used temporarily by the BAM during boot and intended optionally for communication with calibration tools. After reset, calibration tools can immediately write a non-zero value to these registers. The application code, using the registers then as read only, can read them to determine if a calibration tool is attached and operate appropriately.

The compare registers can be used just like 128 bits of memory mapped RAM that is always 0 out of reset, or they can perform a 64-bit to 64-bit compare. The compare function is continuous (combinational logic — not requiring a start or stop). The compare result appears in the MATCH bit in the SIU_CCR register.

The SIU_CARH holds the 32-bit value that is compared against the value in the SIU_CBRH register. The CMPAH field is read/write and is reset by the synchronous reset signal.

Address: Base + 0x0988

Access: R/W

Figure 6-154. Compare A Register High (SIU_CARH)

6.3.1.159 Compare A Register Low (SIU_CARL)

The SIU_CARL register holds the 32-bit value that is compared against the value in the SIU_CBRL register. The CMPAL field is read/write and is reset by the synchronous reset signal.

Address: Base + 0x098C

Access: R/W

Figure 6-155. Compare A Register Low (SIU_CARL)

6.3.1.160 Compare B Register High (SIU_CBRH)

The SIU_CBRH holds the 32-bit value that is compared against the value in the SIU_CARH. The CMPBH field is read/write and is reset by the synchronous reset signal.

Address: Base + 0x0990

Access: R/W

Figure 6-156. Compare B Register High (SIU_CBRH)

6.3.1.161 Compare B Register Low (SIU_CBRL)

The SIU_CBRL holds the 32-bit value that is compared against the value in the SIU_CARL. The CMPBL field is read/write and is reset by the synchronous reset signal.

Figure 6-157. Compare B Register Low (SIU_CBRL)

6.4 Functional Description

The following sections provide an functional overview of the SIU operation.

6.4.1 System Configuration

The following sections describe the system configuration.

6.4.1.1 Boot Configuration

The BOOTCFG[0:1] pins determine the boot mode initiated by the BAM program, and whether external arbitration is selected for external booting. The BAM program uses the BOOTCFG[0] to determine where to read the reset configuration halfword (RCHW), and whether to initiate a FlexCAN or eSCI boot.

Table 6-138 defines the boot modes specified by the BOOTCFG[0:1] pins. If the $\overline{\text{RSTCFG}}$ pin is asserted during the assertion of $\overline{\text{RSTOUT}}$, except in the case of a software external reset, the BOOTCFG pins are latched 4 clock cycles prior to the negation of the $\overline{\text{RSTOUT}}$ pin and are used to update the SIU_RSR and the BAM boot mode. Otherwise, if $\overline{\text{RSTCFG}}$ is negated during the assertion of $\overline{\text{RSTOUT}}$, the BOOTCFG pins are ignored and the boot mode defaults to ‘Boot from internal flash memory.’

Table 6-138. BOOTCFG[0:1] Configuration

Value	Meaning
0b00	Boot from internal flash memory
0b01	FlexCAN/eSCI boot
0b10	Boot from external memory (no arbitration)
0b11	Boot from external memory (external arbitration)

Refer to Section 15.3.2.2.4, “Read the Reset Configuration Halfword” for details on the RCHW.

6.4.1.2 Pad Configuration

The pad configuration registers (SIU_PCR) in the SIU allow software control over the following electrical characteristics of the external pads:

- Weak pullup/down enable/disable
- Weak pullup/down selection
- Slew-rate selection for outputs
- Drive strength selection for outputs
- Input buffer enable (when direction is configured for output)
- Input hysteresis enable/disable
- Open drain/push-pull output selection
- Multiplexed function selection
- Data direction selection

The pad configuration registers are provided to allow centralized control over external pins that are shared by more than one module. Each pad configuration register controls a single pin.

6.4.2 Reset Control

The reset controller logic is located in the SIU. Refer to [Section 6.2.1.1, “Reset Input \(RESET\)”](#) and [Section 6.2.1.2, “Reset Output \(RSTOUT\)”](#) for details on the reset operations.

6.4.2.1 $\overline{\text{RESET}}$ Pin Glitch Detect

The reset controller provides a glitch detect feature on the $\overline{\text{RESET}}$ pin. If the reset controller detects that the $\overline{\text{RESET}}$ pin is asserted for more than two clock cycles, the event is latched. After the latch is set, if the $\overline{\text{RESET}}$ pin is negated before 10 clock cycles is reached, the reset controller sets the RGF bit without affecting any of the other bits in the reset status register (SIU_RSR). The latch is cleared when the RGF bit is set or a valid reset is recognized. The RGF bit remains set until cleared by a software or the $\overline{\text{RESET}}$ signal asserts for 10 clock cycles. The reset controller does not respond to assertions of the $\overline{\text{RESET}}$ pin if a reset cycle is already being processed.

6.4.3 External Interrupt

There are sixteen external interrupt inputs $\overline{\text{IRQ}}[0]–\overline{\text{IRQ}}[15]$ to the SIU. The IRQ inputs can be configured for rising-edge events, falling-edge events, or both. Each IRQ input has a flag bit in the external interrupt status register (SIU_EISR). The flag bits for the $\overline{\text{IRQ}}[4:15]$ inputs are OR'ed together to form one interrupt request to the interrupt controller (OR function performed in the integration glue logic). The flag bits for the $\overline{\text{IRQ}}[0:3]$ inputs can generate either an interrupt request to the interrupt controller or a DMA transfer request to the DMA controller.

[Figure 6-158](#) shows the DMA and interrupt request connections to the interrupt and DMA controllers.

The SIU contains an overrun request for each IRQ and one combined overrun request which is the logical OR of the individual overrun requests. Only the combined overrun request is used in the device, and the individual overrun requests are not connected.

Each IRQ pin has a programmable filter for rejecting glitches on the IRQ signals. The filter length for the IRQ pins is specified in the external IRQ digital filter register (SIU_IDFR).

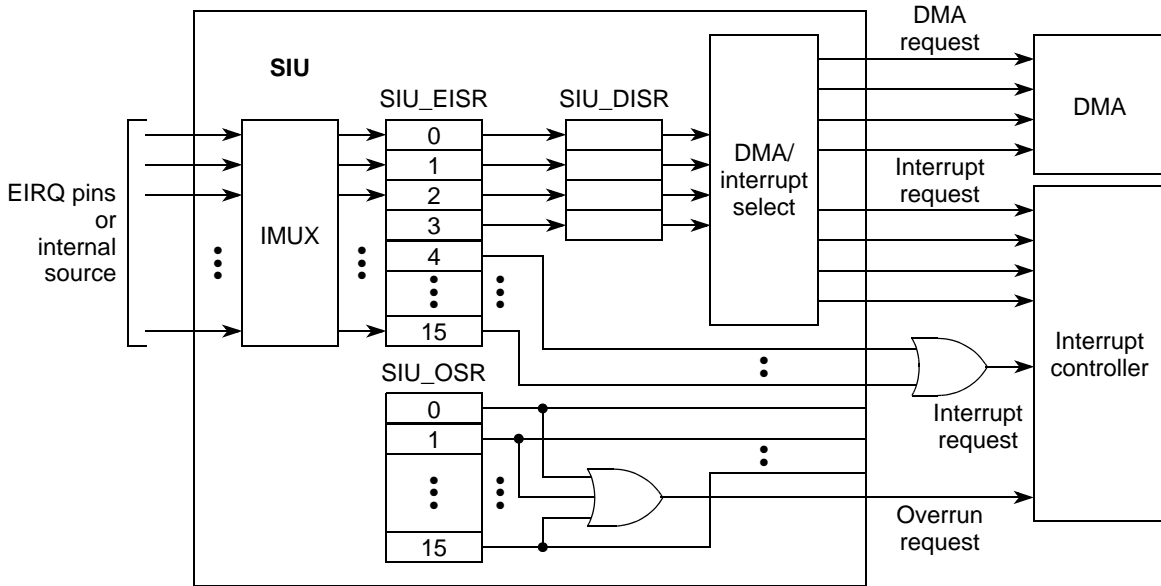

Figure 6-158. SIU DMA/Interrupt Request Diagram

6.4.4 GPIO Operation

All GPIO functions for the device are provided by the SIU. Each device pad that has a GPIO signal has a pin configuration register (PCR) in the SIU where the GPIO function is selected. In addition, each device GPIO signal has an input data register (SIU_GPDI n) and an output data register (SIU_GPDO n).

6.4.5 Internal Multiplexing

The internal multiplexing select registers (SIU_ETISR, SIU_EIISR, and SIU_DISR) select the input source for the following components:

- eQADC external trigger input signals
- SIU external interrupt request signals
- DSPI signals used for chaining serial and parallel DSPI modules

A block diagram of the internal multiplexing feature is shown in [Figure 6-159](#). The figure shows the multiplexing of four external signals to an SIU output. A 2-bit SEL field from an SIU select register defines the input to the multiplexor.

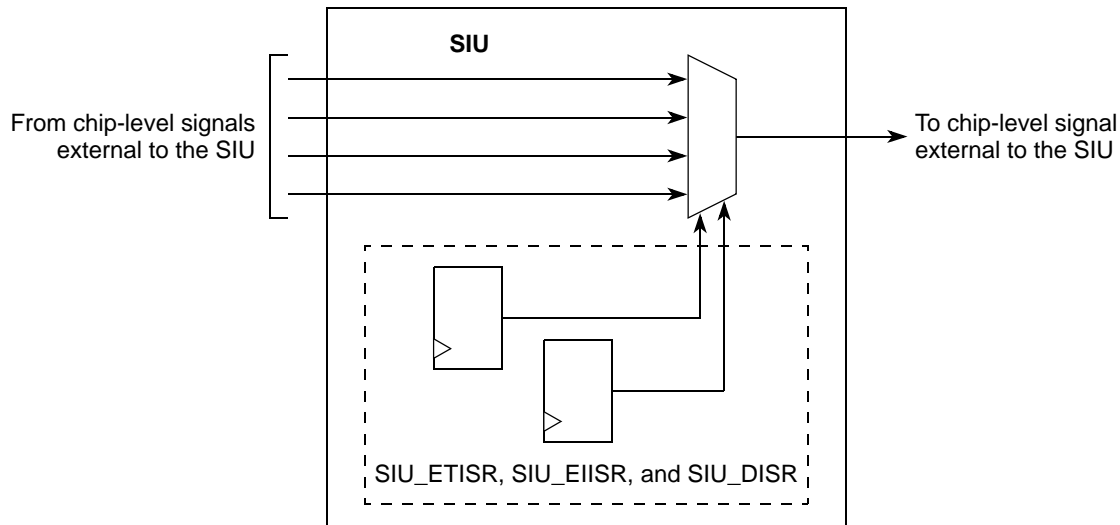

Figure 6-159. Four-to-One Internal Multiplexing Block Diagram

6.4.5.1 eQADC External Trigger Input Multiplexing

The six eQADC external trigger inputs can be connected to one of the following pins:

- External pin
- eTPU channel
- eMIOS channel

The input source for each eQADC external trigger is configured in the eQADC trigger input select register (SIU_ETISR). As shown in the figure, the ETRIG[0] input of the eQADC can be connected to either the ETRIG[0]_GPIO[111] pin, the ETPUA[30] channel, the EMIOS[10] channel, or the GPIO[206] pin. The remaining ETRIG inputs are multiplexed in the same manner. If an ETRIG input is connected to an eTPU or eMIOS channel, the external pin used by that channel can be used by the alternate function on that pin.

An example of the multiplexing of an eQADC external trigger input is given in [Figure 6-160](#).

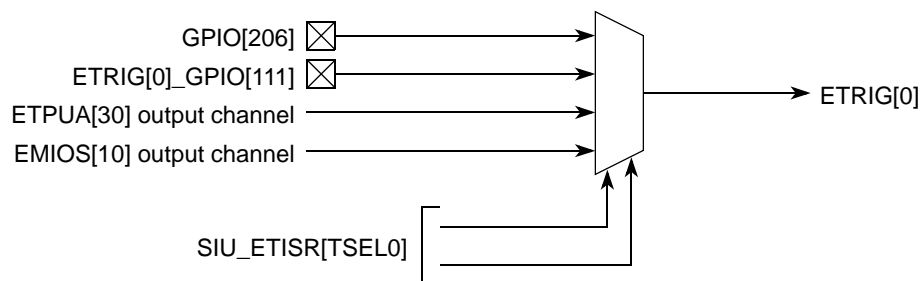

Figure 6-160. eQADC External Trigger Input Multiplexing

Refer to [Section 6.3.1.153, “eQADC Trigger Input Select Register \(SIU_ETISR\)”](#) for the SIU_ETISR[TSEL0]–SIU_ETISR[TSEL5] bit definitions.

6.4.5.2 SIU External Interrupt Input Multiplexing

The sixteen SIU external interrupt inputs can be connected to either an external pin or to serialized output signals from a DSPI module. The input source for each SIU external interrupt is individually specified in the external IRQ input select register (SIU_EIISR).

As shown in the figure, the $\overline{\text{IRQ}}[0]$ input of the SIU can be connected to either the $\overline{\text{IRQ}}[0]_{\text{GPIO}}[203]$ pin, the PCSB[0] serial input signal, the PCSC[1] deserialized output signal, or the PCSD[2] deserialized output signal. The remaining IRQ inputs are multiplexed in the same manner. The inputs to the IRQ from each DSPI module are offset by one so that if more than one DSPI module is connected to the same external device type, a separate interrupt can be generated for each device. This also applies to DSPI modules connected to external devices of different type that have status bits in the same bit location of the deserialized information.

An example of the multiplexing of an SIU external interrupt input is given in [Figure 6-161](#).

Figure 6-161. DSPI Serialized Input Multiplexing

6.4.5.3 Multiplexed Inputs for DSPI Multiple Transfer Operation

Each DSPI module can be combined in a serial or parallel chain (multiple transfer operation). Serial chaining allows SPI operation with an external device that has more bits than one DSPI module.

In a serial chain, one DSPI module operates as a master, the second, third, or fourth DSPI modules operate as slaves. The data output (SOUT) of the master is connected to the data input (SIN) of the slave. The SOUT of a slave is connected to the SIN of subsequent slaves until the last module in the chain, where the SOUT is connected to an external pin, which connects to the input of an external SPI device. The slave DSPI and external SPI device use the master peripheral chip select (PCS) and clock (SCK). The trigger input of the master allows a slave DSPI to trigger a transfer when a data change occurs in the slave DSPI and the slave DSPI is operating in change in data mode. The trigger input of the master is connected to the $\overline{\text{MTRIG}}$ output of the slave. If more than two DSPIs are chained in change in data mode, a chain must be connected of $\overline{\text{MTRIG}}$ outputs to trigger inputs through the slaves with the last slave $\overline{\text{MTRIG}}$ output connected to the master trigger input.

An example of a serial chain is shown in [Figure 6-162](#).

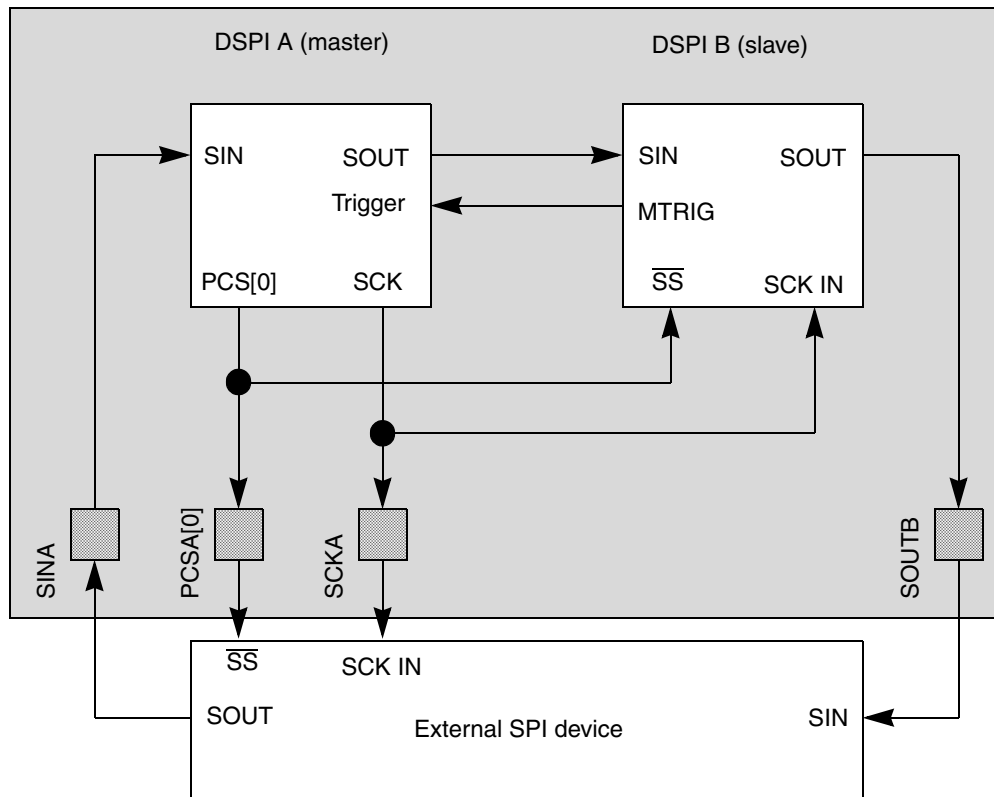

Figure 6-162. DSPI Serial Chaining

Parallel chaining allows the PCS and SCK from one DSPI to be used by more than one external SPI device, thus reducing pin utilization of the device MCU. In this example, the SOUT and SIN of the two DSPIs connect to separate external SPI devices, which share a common PCS and SCK.

To support multiple transfer operation of the DSPIs, an input multiplexor is required for the SIN, \overline{SS} , SCK IN, and trigger signals of each DSPI. The input source for the SIN input of a DSPI can be a pin or the SOUT of any of the other three DSPIs. The input source for the \overline{SS} input of a DSPI can be a pin or the PCSX[0] of any of the other three DSPIs. The input source for the SCK input of a DSPI can be a pin or the SCK output of any of the other three DSPIs. The input source for the trigger input can be the \overline{PCSS} output of any of the other three DSPIs. The input source for each DSPI SIN, \overline{SS} , SCK, and trigger signal is individually specified in the DSPI input select register (SIU_DISR).

An example of a parallel chain is shown in [Figure 6-163](#).

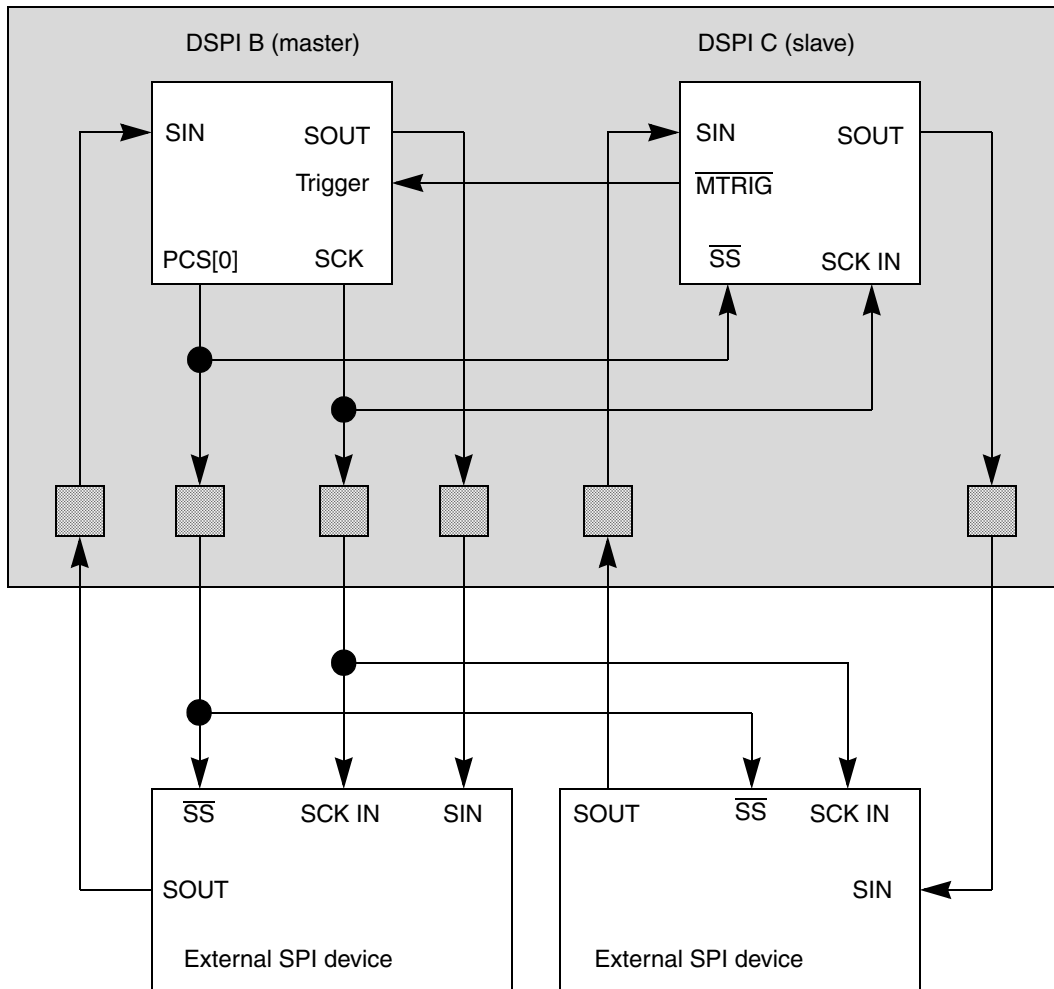

Figure 6-163. DSPI Parallel Chaining

6.5 Document Revision History

Table 6-140. Changes Between MPC5565RM Revisions 0.1 and 1

Added the word 'internal' to the note in the Reset Output ($\overline{\text{RSTOUT}}$) signal description to read 'During an internal power-on-reset (POR) $\overline{\text{RSTOUT}}$ is tri-stated.'

Changes to table 6-6 *SIU_MIDR Field Descriptions*:

- Removed reference to the Signals chapter.
- Added overbars on IRQ signals and put [] around the IRQ variable *n* in text.

Added BASE + 0x18 and Base + 0x1C in the Memory and Register Map Definition section in Table 6-5.

Table 6-140. Changes Between MPC5565RM Revisions 0.1 and 1 (continued)

<p>Table 6-1 <i>Features</i>: Incorporated the following changes: Changed the Pad configuration operations row, Feature column From: SIU registers allow software to initialize the following electrical characteristics of the I/O pins:</p> <ul style="list-style-type: none"> • which multiplexed function is selected • whether the pin is pullup or pulldown • the signal slew rate • the open drain mode for output pins • hysteresis on input pins • drive strength of bus signals <p>To: Enables the configuration and initialization of the I/O pin electrical characteristics via software to select the following:</p> <ul style="list-style-type: none"> • Active function from the set of multiplexed functions • Pullup/down characteristics of the pin • Slew rate for slow and medium pads • Open drain mode for output pins • Hysteresis for input pins • Drive strength of bus signals for fast pads
<p>Table 6-6 <i>SIU_MIDR Field Descriptions</i>: Changed the descriptions of the CSP and PKG fields in the SIU_MIDR register: CSP — Added a note to the CSP description: “Use CSP with PKG to implement calibration functionality.” PKG — Corrected the conditional text in the PCKCFG notes for the MPC5565. Specified the following PKG bit values per product:</p> <p>MPC5565 000 Selects for Legacy compatibility 001–01x Reserved 100 Reserved 101 Selects the 324 package (set CSP low) 110 Selects the 496 Calibration assembly (set CSP high) 111 Reserved</p>
<p>Changed the footnote in the RESET status (SIU_RSR) register to emphasize the fact that any reset and not just a power on reset determines the WKPCFG value: FROM: “The reset value of the WKPCFG bit is determined by the value on the WKPCFG pin at reset.” TO: “The reset value of the WKPCFG bit is determined by the value on the WKPCFG pin at any reset.” Changed all registers to have both the MSB and LSB conditional text register bit numbering.</p>

Section 6.3.1.44, "Pad Configuration Register 82–75 (SIU_PCR82–SIU_PCR75) Changed order of MDO[11:4]_GPIO[82:75] to MDO[4:11]_GPIO[75:82].
Table 6-41 <i>PCR83 PA Field Definitions</i> : Removed TXDA from MPC5565 in the register description and the table entry.
Table 6-42 <i>PCR84 PA Field Definitions</i> : Removed RXDA from MPC5565 in the register description and the table entry.
Table 6-92 Changed conditional text to show PCSA[5] in table and register description.
Section 6.4.2.1, "RESET Pin Glitch Detect" First paragraph: added '(SIU_RSR)' after 'reset status register' in line four.
Section 6.4.4, "GPIO Operation Changed 'GPDO _n ' and 'GPDIn _n ' to 'GPDO _n ' and 'GPDIn'.
Table 6-6 " <i>SIU_MIDR Field Descriptions</i> ": Removed the note in the CSP row " Use CSP with PKG to implement calibration functionality. Removed comments in PKG row (after CSP row) pertaining to CSP.
Figure 6-72 <i>ETRIG[0:1]_GPIO[111:112] Pad Configuration Register (SIU_PCR112–SIU_PCR112)</i> : Removed "When ETRIG[0:1] is configured, the OBE has no effect" from footnote 2.
Section 6.3.1.44, "Pad Configuration Register 82–75 (SIU_PCR82–SIU_PCR75) Changed order of MDO[4:11]_GPIO[75:82] to MDO[11:4]_GPIO[82:75].
Section 6.4.2.1, "RESET Pin Glitch Detect" Corrected incomplete sentence "The latch is cleared when the RGF bit is set in the SIU_RSR or a valid reset is recognized." Added 'SIU_RSR.'
Section 6.2.1.6.2, "DMA Transfers" Rewrote paragraph to clarify that only 4 DMA transfer/IRQ requests are selectable ($\overline{\text{IRQ}}[0]$ through $\overline{\text{IRQ}}[3]$).
Table 6-41 <i>PCR83 PA Field Definitions</i> : Added back in TXDA in the register description and the table entry.
Table 6-42 <i>PCR84 PA Field Definitions</i> : Added back in RXDA in the register description and the table entry.
Table 6-26 <i>PCR49 PA Field Definitions</i> : Corrected values for PCR entries.
Table 6-28 <i>PCR51 PA Field Definitions</i> : Corrected the table title from PCR49 to PCR51 and the values for PCR entries.
Throughout this chapter, replaced 'Reserved' with 'Invalid value' for all R/W fields that have invalid values.

Chapter 7

Crossbar Switch (XBAR)

7.1 Introduction

This chapter describes the multi-port crossbar switch (XBAR), which supports simultaneous connections between three master ports and five slave ports. XBAR supports a 32-bit address bus width and a 64-bit data bus width at all master and slave ports.

7.1.1 Block Diagram

Figure 7-1 shows a block diagram of the crossbar switch.

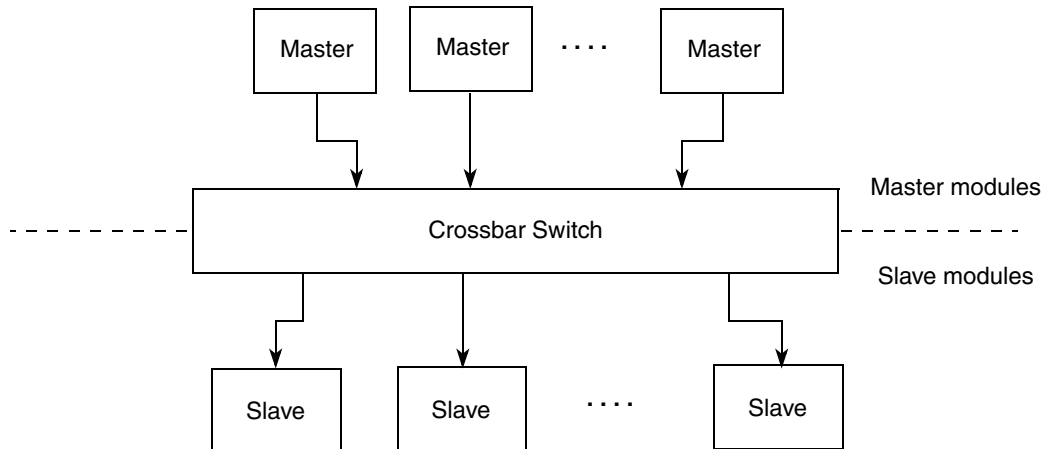

Figure 7-1. XBAR Block Diagram

Table 7-1 gives the crossbar switch port for each master and slave, and the assigned and fixed ID number for each master. The following table shows the master ID numbers as they relate to the master port numbers:

Table 7-1. XBAR Switch Ports

Module	Port		Master ID
	Type	Number	
e200z6 core–CPU instruction / data	Master	0	0
e200z6–Nexus	Master	0	1
eDMA	Master	1	2
External bus interface	Master	2	3
Flash	Slave	0	—

Table 7-1. XBAR Switch Ports (continued)

Module	Port		Master ID
	Type	Number	
External bus interface	Slave	1	—
Internal SRAM	Slave	3	—
Peripheral bridge A (PBRIDGE_A)	Slave	6	—
Peripheral bridge B (PBRIDGE_B)	Slave	7	—

7.1.2 Overview

The XBAR allows for concurrent transactions to occur from any master port to any slave port. It is possible for all master ports and slave ports to be in use at the same time as a result of independent master requests. If a slave port is simultaneously requested by more than one master port, arbitration logic selects the higher priority master and grant it ownership of the slave port. All other masters requesting that slave port are stalled until the higher priority master completes its transactions.

By default, requesting masters are granted access based on a fixed priority. A round-robin priority mode also is available. In this mode, requesting masters are treated with equal priority and are granted access to a slave port in round-robin fashion, based upon the ID of the last master to be granted access. A block diagram of the XBAR is shown in [Figure 7-1](#).

The XBAR can place a slave port in a low-power park mode to avoid dissipating any power transitional address, control or data signals when the master port is not actively accessing the slave port. There is a one-cycle arbitration overhead for exiting low-power park mode.

7.1.3 Features

- Three master ports:
 - core: e200z6 core and Nexus
 - eDMA
 - EBI
- Five slave ports
 - Flash (refer to [Chapter 13, “Flash Memory”](#) for information on accessing flash memory)
 - EBI
 - Internal SRAM
 - Peripheral bridge A
 - Peripheral bridge B
- 32-bit address, 64-bit data paths
- Fully concurrent transfers between independent master and slave ports

7.1.4 Modes of Operation

7.1.4.1 Normal Mode

In normal mode, the XBAR provides the register interface and logic that controls crossbar switch configuration.

7.1.4.2 Debug Mode

The XBAR operation in debug mode is identical to operation in normal mode.

7.2 Memory Map and Register Definition

The memory map for the XBAR program-visible registers is shown in [Table 7-2](#).

Table 7-2. XBAR Register Memory Map

Address	Register Name	Register Description	Bits
Base = 0xFFFF0_4000	XBAR_MPR0	Master priority register for slave port 0	32

Base + 0x0700	XBAR_MPR7	Master priority register for slave port 7	32

Table 7-2. XBAR Register Memory Map (continued)

Address	Register Name	Register Description	Bits
Base + 0x0704– Base + 0x070F	—	Reserved	—
Base + 0x0710	XBAR_SGPCR7	General-purpose control register for slave port 7	32
Base + 0x0714– Base + 0x0003_FFFF	—	Reserved	—

7.2.1 Register Descriptions

There are two registers for each slave port of the XBAR. The registers can only be accessed in supervisor mode using 32-bit accesses.

The slave SGPCR also features a bit (RO), which when written with a 1, prevents all slave registers for that port from being written to again until a reset occurs. The registers remain readable, but future write attempts have no effect on the registers and are terminated with an error response.

The difference in numerical values of XBAR Master Port and Master ID is shown in [Table 7-3](#).

Table 7-3. XBAR Switch Ports

Module	Port	Master ID
	Type Number	
e200z6 core—CPU instruction / data	Master 0	0
e200z6—Nexus	Master 0	1
eDMA	Master 1	2
External bus interface	Master 2	3
Flash	Slave 0	—
External bus interface	Slave 1	—
Internal SRAM	Slave 3	—
Peripheral bridge A (PBRIDGE_A)	Slave 6	—
Peripheral bridge B (PBRIDGE_B)	Slave 7	—

7.2.1.1 Master Priority Registers (XBAR_MPR_n)

The XBAR_MPR for a slave port sets the priority of each master port when operating in fixed priority mode. They are ignored in round-robin priority mode unless more than one master has been assigned high priority by a slave.

NOTE

Masters must be assigned unique priority levels.

The master priority register can only be accessed in supervisor mode with 32-bit accesses. After the read only (RO) bit is set in the slave general-purpose control register, the master priority register can only be read. Attempts to write to it have no effect on the MPR and result in an error.

NOTE

XBAR_MPR must be written with a read/modify/write for code compatibility.

28	Reserved, must be cleared.
29–31 MSTR0	Master 0 priority. Set the arbitration priority for master port 0 on the associated slave port. 000 This master has the highest priority when accessing the slave port. ⋮ 010 This master has the lowest priority when accessing the slave port. 011–111 Invalid values

7.2.1.2 Slave General-Purpose Control Registers (XBAR_SGPCR_n)

The XBAR_SGPCR_n of a slave port controls several features of the slave port, including the following:

- Round-robin or fixed arbitration policy for a particular slave port
- Write protection of any slave port registers
- Parking algorithm used for a slave port

The PARK field indicates which master port this slave port parks on when no active access attempts are being made to the slave and the parking control field is set to park on a specific master.

XBAR_SGPCR_n[PARK] must only be programmed to select master ports that are actually available on the device, otherwise undefined behavior results. The low-power park feature can result in an overall power savings if the slave port is not saturated; however, an extra clock of latency results whenever any master tries to access a slave (not being accessed by another master) because it is not parked on any master.

The XBAR_SGPCR can only be accessed in supervisor mode with 32-bit accesses. After the RO (read only) bit is set in the XBAR_SGPCR, the XBAR_SGPCR and the SBAR_MPR can only be read. Attempts to write to them have no effect and results in an error.

NOTE

Some of the unused bits in the SGPCR_n registers are writeable and readable, but they serve no function. Setting any of these bits has no effect on the operation of this module.

7.3 Functional Description

This section describes the functionality of the XBAR in more detail.

7.3.1 Overview

The main goal of the XBAR is to increase overall system performance by allowing multiple masters to communicate concurrently with multiple slaves. To maximize data throughput, it is essential to keep arbitration delays to a minimum.

This section examines data throughput from the point of view of masters and slaves, detailing when the XBAR stalls masters, or inserts bubbles on the slave side.

7.3.2 General Operation

When a master makes an access to the XBAR from an idle master state, the access is taken immediately by the XBAR. If the targeted slave port of the access is available (that is, the requesting master is currently granted ownership of the slave port), the access is immediately presented on the slave port. It is possible to make single clock (zero wait state) accesses through the XBAR by a granted master. If the targeted slave port of the access is busy or parked on a different master port, the requesting master receives wait states until the targeted slave port can service the master request. The latency in servicing the request depends on each master’s priority level and the responding slave’s access time.

Because the XBAR appears to be simply another slave to the master device, the master device has no indication that it owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it is wait-stated.

A master is given control of a targeted slave port only after a previous access to a different slave port has completed, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when a master has the following conditions:

- Outstanding request to slave port A that has a long response time
- Pending access to a different slave port B
- Lower priority master also makes a request to the different slave port B.

In this case, the lower priority master is granted bus ownership of slave port B after a cycle of arbitration, assuming the higher priority master slave port A access is not terminated.

After a master has control of the slave port it is targeting, the master remains in control of that slave port until it gives up the slave port by running an IDLE cycle, leaves that slave port for its next access, or loses control of the slave port to a higher priority master with a request to the same slave port. However, because all masters run a fixed-length burst transfer to a slave port, it retains control of the slave port until that transfer sequence is completed. In round-robin arbitration mode, the current master is forced to hand off bus ownership to an alternately requesting master at the end of its current transfer sequence.

When a slave bus is idled by the XBAR, it can be parked on the master port using the PARK bits in the XBAR_SGPCR (slave general-purpose control register), or on the last master to have control of the slave port. This can avoid the initial clock of the arbitration delay if the master must arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode to save power.

7.3.3 Master Ports

The XBAR terminates an access and it is not allowed to pass through the XBAR unless the master currently is granted access to the slave port to which the access is targeted. A master access is taken if the slave port to which the access decodes is either currently servicing the master or is parked on the master. In this case, the XBAR is completely transparent and the master access is immediately transmitted on the slave bus and no arbitration delays are incurred. A master access stall if the access decodes to a slave port that is busy serving another master, parked on another master or is in low-power park mode.

If the slave port is currently parked on another master or is in low-power park mode, and no other master is requesting access to the slave port, then only one clock of arbitration is incurred. If the slave port is currently serving another master of a lower priority and the master has a higher priority than all other requesting masters, then the master gains control over the slave port as soon as the data phase of the current access is completed. If the slave port is currently servicing another master of a higher priority, then the master gains control of the slave port after the other master releases control of the slave port if no other higher priority master is also waiting for the slave port.

A master access is responded to with an error if the access decodes to a location not occupied by a slave port. This is the only time the XBAR directly responds with an error response. All other error responses received by the master are the result of error responses on the slave ports being passed through the XBAR.

7.3.4 Slave Ports

The goal of the XBAR with respect to the slave ports is to keep them 100% saturated when masters are actively making requests. To do this the XBAR must not insert any bubbles onto the slave bus unless absolutely necessary.

There is only one instance when the XBAR forces a bubble onto the slave bus when a master is actively making a request. This occurs when a handoff of bus ownership occurs and there are no wait states from the slave port. A requesting master which does not own the slave port is granted access after a one clock delay.

The only other time the XBAR has control of the slave port is when no masters are making access requests to the slave port and the XBAR is forced to either park the slave port on a specific master, or place the slave port into low-power park mode. In these cases, the XBAR forces IDLE for the transfer type.

7.3.5 Priority Assignment

Each master port must be assigned a unique 2-bit priority level in fixed priority mode. If multiple master ports are assigned the same priority level within a register (XBAR_MPR) undefined behavior results.

7.3.6 Arbitration

XBAR supports two arbitration schemes; a simple fixed-priority comparison algorithm, and a round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

7.3.6.1 Fixed Priority Operation

When operating in fixed-priority arbitration mode, each master is assigned a unique priority level in the XBAR_MPR. If two masters both request access to a slave port, the master with the highest priority in the selected priority register gains control over the slave port.

Any time a master makes a request to a slave port, the slave port checks to see if the new requesting master's priority level is higher than that of the master that currently has control over the slave port (if any). The slave port does an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently has control of the slave port, the higher priority master is granted control at the termination of any currently pending access, assuming the pending transfer is not part of a burst transfer.

A new requesting master must wait until the end of the fixed-length burst transfer, before it is granted control of the slave port. But if the new requesting master's priority level is lower than that of the master that currently has control of the slave port, the new requesting master is forced to wait until the master that currently has control of the slave port is finished accessing the current slave port.

7.3.6.2 Round-Robin Priority Operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the port number of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes the owner of the slave bus at the next transfer boundary (accounting for fixed-length burst transfers). Priority is based on how far ahead the port number of the requesting master is to the port number of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port when the current transfer is completed, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the three masters have ID's 0, 1, and 2. If the last master of the slave port was master 1, and masters 0 and 2 make simultaneous requests, they are serviced in the order 2 and then 0 assuming no further requests are made.

As another example, if master 1 is waiting on a response from a slow slave and has no further pending access to that slave, no other masters are requesting, and master 0 then makes a request, master 0's request is granted on the next clock (assuming that master 1's transfer is not a burst transfer), and the request information for master 0 is driven to the slave as a pending access. If master 2 were to make a request after master 0 has been granted access, but prior to master 0's access being accepted by the slave, master 0 maintains the grant on the slave port, and master 2 is delayed until the next arbitration boundary, which occurs after the transfer is complete. The round-robin pointer is reset to 0, so if master 1 has another request that occurs before master 0's transfer completes, master 1 is the granted the bus. This implies a worst case latency of N transfers for a system with N masters.

Parking may continue to be used in round-robin mode, but affects the round-robin pointer unless the parked master actually performs a transfer. Handoff to the next master in line occurs after one cycle of arbitration.

The slave port does an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

A new requesting master must wait until the end of the fixed-length burst transfer, before it is granted control of the slave port. If the new requesting master's priority level is lower than that of the master that currently has control of the slave port, the new requesting master is forced to wait until the master that currently has control of the slave port completes its access.

7.3.6.2.1 Parking

If no master is currently requesting the slave port, the slave port is parked. The slave port parks in one of three places, indicated by the value of the PCTL field in the XBAR_SGPCR.

- If park-on-specific master mode is selected, the slave port parks on the master designated by the PARK field. When the master accesses the slave port again, a one clock arbitration penalty is incurred only for an access request made by another master port to the slave port. No other arbitration penalties are incurred. All other masters pay a one clock penalty.
- If park-on-last (POL) mode is selected, then the slave port parks on the last master to access it, passing that master's signals through to the slave bus. When the master accesses the slave port again, no other arbitration penalties are incurred except that a one clock arbitration penalty is incurred for each access request to the slave port made by another master port. All other masters pay a one clock penalty.
- If the low-power-park (LPP) mode is selected, then the slave port enters low-power park mode. It is not under control by any master and does not transmit any master signals to the slave bus. All slave bus activity halts because all slave bus signals are not toggling. This saves power if the slave port is not used for some time. However, when a master does make a request to a slave port parked in low-power-park, a one clock arbitration delay is incurred to get ownership of the slave port.

7.4 Document Revision History

Table 7-6. Changes Between MPC5565RM Revisions 0.1 and 1

Added to Register Descriptions section: “Please note the difference in numerical values of XBAR Master Port and Master ID as shown in [Table 7-3](#).”

Changed wording of reserved fields in registers:

- From: “Reserved”
- To: “Reserved, must be cleared.”

Table 7-4 *XBAR_MPRn Descriptions*: Added text for MPR3 and MPR6 fields that all other values than those stated are invalid. Changed ‘Reserved’ to ‘Invalid value’.

Figure 7-2 *XBAR_MPRn Register*: Made MPR3 (not included) and MPR6 (not included) fields visible and read/write.

Table 7-5 *XBAR_SCPCRn Field Descriptions*: Changed ‘Reserved’ values for the Park field to ‘Invalid value’.

Chapter 8

Error Correction Status Module (ECSM)

8.1 Introduction

The device includes error-correcting code (ECC) implementations to improve the quality and reliability of internal SRAM and internal flash memories. The error correction status module (ECSM), provides a means for the application to collect information on memory errors reported by ECC and/or generic access error information.

8.1.1 Overview

The ECSM provides a set of registers that configure and report ECC errors for the device including accesses to SRAM and Flash memory. The application may configure the device for the types of memory errors to be reported, and then query a set of read-only status and information registers to identify any errors that have been signalled.

There are two types of ECC errors: correctable and non-correctable. A correctable ECC error is generated when only one bit is wrong in a 64-bit doubleword. In this case it is corrected automatically by hardware, and no flags or other indication is set that the error occurred. A non-correctable ECC error is generated when 2 bits in a 64-bit doubleword are incorrect. Non-correctable ECC errors cause an interrupt, and if enabled, additional error details are available in the ECSM.

Error correction is implemented on 64 bits of data at a time, using 8 bits for ECC for every 64-bit doubleword. ECC is checked on reads, and calculated on writes per the following:

1. 64 bits containing the desired byte / halfword / word or doubleword in memory is read, and ECC checked.
2. If the access is a write, then
 - The new byte / halfword / word / doubleword is merged into the 64 bits.
 - New ECC bits are calculated.
 - The 64 bits and the new ECC bits are written back.

To use ECC with SRAM, the SRAM memory must be written to before ECC is enabled. Refer to [Section 8.3, “Initialization and Application Information.”](#)

8.1.2 Features

The ECSM includes these features:

- Configurable for reporting non-correctable errors
- Registers for capturing ECC information for RAM and flash access errors

8.2 Memory Map and Register Definition

Table 8-1 is the memory map for the ECSM registers.

Table 8-2. ECSM Memory Map

¹ These registers control and configure a software watchdog timer, and are included as part of a standard Freescale ECSM module. The e200z6 core also provides this functionality and is the preferred method for watchdog implementation. Refer to Section 8.2.1.1, “Software Watchdog Timer Control, Service, and Interrupt Registers (ECSM_SWTCR, ECSM_SWTSR, and ECSM_SWTIR).”

8.2.1 Register Descriptions

Attempted accesses to reserved addresses result in an error termination, while attempted writes to read-only registers are ignored and do not terminate with an error. Unless noted otherwise, writes to the programming model must match the size of the register; for example, an n -bit register only supports n -bit writes, etc. Attempted writes of a different size than the register width produce an error termination of the bus cycle and no change to the targeted register.

8.2.1.1 Software Watchdog Timer Control, Service, and Interrupt Registers (ECSM_SWTCR, ECSM_SWTSR, and ECSM_SWTIR)

These registers provide control and configuration for a software watchdog timer, and are included as part of a standard Freescale ECSM module incorporated in the device. The e200z6 core also provides this functionality and is the preferred method for watchdog implementation. To optimize code portability to other members of this Power Architecture-based MPU family, use of the watchdog registers in the ECSM is not recommended.

The values in these registers should be left in their reset state. Any change from reset values may cause an unintentional ECSM_SWTIR_SWTIC interrupt.

8.2.1.2 ECC Registers

There are a number of program-visible registers for the sole purpose of reporting and logging of memory failures. These registers include the following:

- ECC configuration register (ECSM_ECR)
- ECC status register (ECSM_ESR)
- ECC error generation register (EEGR)
- Flash ECC address register (ECSM_FEAR)
- Flash ECC master number register (ECSM_FEMR)
- Flash ECC attributes register (ECSM_FEAT)
- Flash ECC data register (ECSM_FEDR)
- RAM ECC address register (ECSM_REAR)
- RAM ECC master number register (ECSM_REMR)
- RAM ECC attributes register (ECSM_REAT)
- RAM ECC data register (ECSM_REDR)

The details on the ECC registers are provided in the subsequent sections.

8.2.1.3 ECC Configuration Register (ECSM_ECR)

The ECSM_ECR is an 8-bit control register for specifying whether memory errors are reported during RAM or Flash accesses. The occurrence of a non-correctable error causes the current access to be terminated with an error condition. In many cases, this error termination is reported directly by the initiating bus master. The ECC reporting logic in the ECSM provides an optional error interrupt mechanism to signal non-correctable memory errors. In addition to the interrupt generation, the ECSM

captures specific information (memory address, attributes and data, bus master number, etc.) which may be useful for subsequent failure analysis.

Figure 8-1. ECC Configuration Register (ECSM_ECR)

Table 8-3. ECSM_ECR Field Definitions

Field	Description
0–5	Reserved.
6 ERNCR	Enable RAM non-correctable reporting. The occurrence of a non-correctable multi-bit RAM error generates a ECSM ECC interrupt request as signalled by the assertion of ECSM_ESR[RNCE]. The faulting address, attributes and data are also captured in the REAR, REMR, REAT and REDR registers. 0 Reporting of non-correctable RAM errors is disabled. 1 Reporting of non-correctable RAM errors is enabled.
7 EFNCR	Enable Flash non-correctable reporting. The occurrence of a non-correctable multi-bit Flash error generates a ECSM ECC interrupt request as signalled by the assertion of ECSM_ESR[FNCE]. The faulting address, attributes and data are also captured in the FEAR, FEMR, FEAT and FEDR registers. 0 Reporting of non-correctable Flash errors is disabled. 1 Reporting of non-correctable Flash errors is enabled.

8.2.1.4 ECC Status Register (ECSM_ESR)

The ECSM_ESR is an 8-bit control register for signaling which types of properly-enabled ECC events have been detected. The ESR signals the last, properly-enabled memory event to be detected. The generation of the ECSM ECC interrupt request is defined by the boolean equation:

```
ECSM_ECC_IRQ
= ECSM_ECR[ERNCR] & ECSM_ESR[RNCE] // ram, noncorrectable error
| ECSM_ECR[EFNCR] & ECSM_ESR[FNCE] // Flash, noncorrectable error
```

where the combination of a properly-enabled category in the ECSM_ECR and the detection of the corresponding condition in the ECSM_ESR produces the interrupt request.

The ECSM allows a maximum of one bit of the ECSM_ESR to be asserted at any given time. This preserves the association between the ECSM_ESR and the corresponding address and attribute registers, which are loaded on each occurrence of an properly-enabled ECC event. If there is a pending ECC interrupt and another properly-enabled ECC event occurs, the ECSM hardware automatically handles the ECSM_ESR reporting, clearing the previous data and loading the new state and thus guaranteeing that only a single flag is asserted.

To maintain the coherent software view of the reported event, the following sequence in the ECSM error interrupt service routine is suggested:

1. Read the ECSM_ESR and save it.
2. Read and save all the address and attribute reporting registers.
3. Re-read the ECSM_ESR and verify the current contents matches the original contents. If the two values are different, go back to step 1 and repeat.
4. When the values are identical, write a 1 to the asserted ECSM_ESR flag to negate the interrupt request.

In the event that multiple status flags are signaled simultaneously, ECSM records the event with the RNCE as highest priority, and then FNCE.

Figure 8-2. ECC Status Register (ECSM_ESR)

Table 8-4. ECSM_ESR Field Definitions

Field	Description
0–5	Reserved.
6 RNCE	RAM non-correctable error. The occurrence of a properly-enabled non-correctable RAM error generates an ECSM ECC interrupt request. The faulting address, attributes and data are also captured in the REAR, REMR, REAT and REDR registers. To clear this interrupt flag, write a 1 to this bit. Writing a 0 has no effect. 0 No reportable non-correctable RAM error has been detected. 1 A reportable non-correctable RAM error has been detected.
7 FNCE	Flash non-correctable error. The occurrence of a properly-enabled non-correctable Flash error generates an ECSM ECC interrupt request. The faulting address, attributes and data are also captured in the FEAR, FEMR, FEAT and FEDR registers. To clear this interrupt flag, write a 1 to this bit. Writing a 0 has no effect. 0 No reportable non-correctable Flash error has been detected. 1 A reportable non-correctable Flash error has been detected.

8.2.1.5 ECC Error Generation Register (ECSM_EEGR)

The ECSM_EEGR is a 16-bit control register used to force the generation of double-bit data errors in the internal SRAM. This capability provides a mechanism to allow testing of the software service routines associated with memory error logging. The intent is to generate errors during data write cycles, such that subsequent reads of the corrupted address locations generate ECC events, double-bit noncorrectable errors that are terminated with an error response.

If an attempt to force a non-correctable error (by asserting ECSM_EEGR[FRCNCI] or ECSM_EEGR[FRC1NCI]) and ECSM_EEGR[ERRBIT] equals 64, then no data error will be generated.

NOTE

The only allowable values for the 2 control bit enables {FRCNCI, FR1NCI} are {0,0}, {1,0} and {0,1}. The value {1,1} results in undefined behavior.

Figure 8-3. ECC Error Generation (ECSM_EEGR) Register

Table 8-5. ECSM_EEGR Field Definitions

Field	Description
0–5	Reserved
6 FRCNCI	Force internal SRAM continuous noncorrectable data errors. 0 No internal SRAM continuous 2-bit data errors are generated. 1 2-bit data errors in the internal SRAM are continuously generated. The assertion of this bit forces the internal SRAM controller to create 2-bit data errors, as defined by the bit position specified in ERRBIT[0:6] and the overall odd parity bit, continuously on every write operation. The normal ECC generation takes place in the RAM controller, but then the polarity of the bit position defined by ERRBIT and the overall odd parity bit are inverted to introduce a 2-bit ECC error in the RAM.
7 FR1NCI	Force internal SRAM one noncorrectable data errors. 0 No internal SRAM single 2-bit data errors are generated. 1 One 2-bit data error in the internal SRAM is generated. The assertion of this bit forces the internal SRAM controller to create one 2-bit data error, as defined by the bit position specified in ERRBIT[0:6] and the overall odd parity bit, on the first write operation after this bit is set. The normal ECC generation takes place in the internal SRAM controller, but then the polarity of the bit position defined by ERRBIT and the overall odd parity bit are inverted to introduce a 2-bit ECC error in the RAM. After this bit has been enabled to generate a single 2-bit error, it must be cleared before being set again to properly re-enable the error generation logic.
8	Reserved
9–15 ERRBIT	Error bit position. Defines the bit position which is complemented to create the data error on the write operation. The bit specified by this field plus the odd parity bit of the ECC code are inverted. The internal SRAM controller follows a vector bit ordering scheme where LSB=0. Errors in the ECC syndrome bits can be generated by setting this field to a value greater than the internal SRAM width. The following association between the ERRBIT field and the corrupted memory bit is defined: if ERRBIT = 0, then RAM[0] is inverted if ERRBIT = 1, then RAM[1] is inverted ... if ERRBIT = 63, then RAM[63] is inverted if ERRBIT = 64, then ECC Parity[0] is inverted if ERRBIT = 65, then ECC Parity[1] is inverted ... if ERRBIT = 71, then ECC Parity[7] is inverted For ERRBIT values greater than 71, no bit position is inverted.

8.2.1.6 Flash ECC Address Register (ECSM_FEAR)

The ECSM_FEAR is a 32-bit register for capturing the address of the last, properly-enabled ECC event in the Flash memory. Depending on the state of the ECSM_ECR, an ECC event in the Flash causes the address, attributes and data associated with the access to be loaded into the ECSM_FEAR, ECSM_FEMR, ECSM_FEAT, and ECSM_FEDR registers, and the appropriate flag (F1BC or FNCE) in the ECSM_ESR to be asserted.

The address that is captured in ECSM_FEAR is the Flash page address as seen on the system bus. Refer to [Section 13.3.2.7, “Address Register \(FLASH_AR\)”](#) to retrieve the doubleword address.

Figure 8-4. Flash ECC Address Register (ECSM_FEAR)

Table 8-6. ECSM_FEAR Field Descriptions

Field	Description
0–31 FEAR [0:31]	Flash ECC address. Contains the faulting access address of the last, properly-enabled Flash ECC event.

8.2.1.7 Flash ECC Master Number Register (ECSM_FEMR)

The FEMR is an 8-bit register for capturing the XBAR bus master number of the last, properly-enabled ECC event in the Flash memory. Depending on the state of the ECSM_ECR, an ECC event in the Flash causes the address, attributes and data associated with the access to be loaded into the ECSM_FEAR, ECSM_FEMR, ECSM_FEAT and ECSM_FEDR registers, and the appropriate flag (FNCE) in the ECSM_ESR to be asserted.

¹ “U” signifies a bit that is uninitialized.

Figure 8-5. Flash ECC Master Number Register (ECSM_FEMR)

Table 8-7. ECSM_FEMR Field Descriptions

Field	Description
0–3	Reserved.
4–7 FEMR [0:3]	Flash ECC master number. Contains the XBAR bus master number of the faulting access of the last, properly-enabled Flash ECC event. The reset value of this field is undefined.

8.2.1.8 Flash ECC Attributes Register (ECSM_FEAT)

The ECSM_FEAT is an 8-bit register for capturing the XBAR bus master attributes of the last, properly-enabled ECC event in the Flash memory. Depending on the state of the ECSM_ECR register, an ECC event in the Flash causes the address, attributes, and data associated with the access to be loaded into the ECSM_FEAR, ECSM_FEMR, ECSM_FEAT, and ECSM_FEDRs, and the appropriate flag (FNCE) in the ECSM_ESR to be asserted.

¹ “U” signifies a bit that is uninitialized.

7 PROT3	Protection: type. The reset value of this field is undefined. 0 I-Fetch 1 Data

8.2.1.9 Flash ECC Data High Register (ECSM_FEDRH)

The ECSM_FEDRH and ECSM_FEDRL are 32-bit registers for capturing the data associated with the last, properly-enabled ECC event in the Flash memory. Depending on the state of the ECSM_ECR, an ECC event in the Flash causes the address, attributes and data associated with the access to be loaded into the ECSM_FEAR, ECSM_FEMR, ECSM_FEAT and ECSM_FEDRs, and the appropriate flag (FNCE) in the ECSM_ESR to be asserted.

The data captured on a multi-bit non-correctable ECC error is undefined.

Figure 8-7. Flash ECC Data High Register (ECSM_FEDRH)

Table 8-9. ECSM_FEDRH Field Descriptions

Field	Description
0–31 FEDH [0:31]	Flash ECC data. Contains the data associated with the faulting access of the last, properly-enabled Flash ECC event. The register contains the data value taken directly from the data bus. The reset value of this field is undefined.

8.2.1.10 Flash ECC Data Low Registers (ECSM_FEDRL)

The ECSM_FEDRH and ECSM_FEDRL are 32-bit registers for capturing the data associated with the last, properly-enabled ECC event in the Flash memory. Depending on the state of the ECSM_ECR, an ECC event in the Flash causes the address, attributes and data associated with the access to be loaded into the ECSM_FEAR, ECSM_FEMR, ECSM_FEAT and ECSM_FEDRs, and the appropriate flag (FNCE) in the ECSM_ESR to be asserted.

The data captured on a multi-bit non-correctable ECC error is undefined.

Figure 8-8. Flash ECC Data Low Register (ECSM_FEDRL)

Table 8-10. ECSM_FEDRL Field Descriptions

Field	Description
0–31 FEDL [0:31]	Flash ECC data. Contains the data associated with the faulting access of the last, properly-enabled Flash ECC event. The register contains the data value taken directly from the data bus. The reset value of this field is undefined.

8.2.1.11 RAM ECC Address Register (ECSM_REAR)

The ECSM_REAR is a 32-bit register for capturing the address of the last, properly-enabled ECC event in the RAM memory. Depending on the state of the ECSM_ECR, an ECC event in the RAM causes the address, attributes and data associated with the access to be loaded into the ECSM_REAR, ECSM_REMR, ECSM_REAT and ECSM_REDRs, and the appropriate flag (RNCE) in the ECSM_ESR to be asserted.

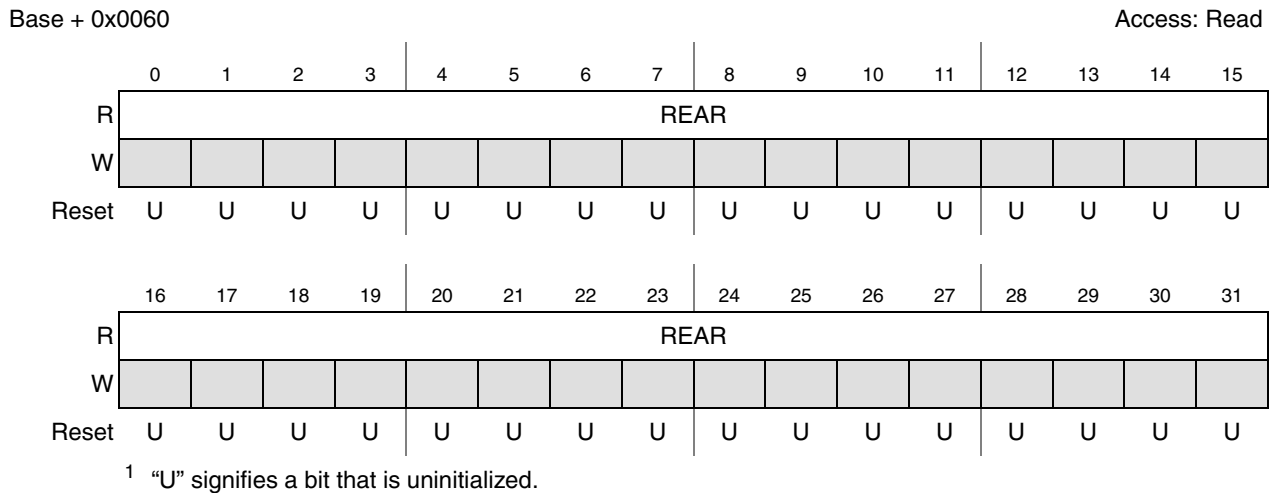

Figure 8-9. RAM ECC Address Register (ECSM_REAR)

Table 8-11. ECSM_REAR Field Descriptions

Field	Description
0–31 REAR [0:31]	RAM ECC address. Contains the faulting access address of the last, properly-enabled RAM ECC event. The reset value of this field is undefined.

8.2.1.12 RAM ECC Master Number Register (ECSM_REMR)

The REMR is an 8-bit register for capturing the XBAR bus master number of the last, properly-enabled ECC event in the RAM memory. Depending on the state of the ECSM_ECR, an ECC event in the RAM causes the address, attributes and data associated with the access to be loaded into the ECSM_REAR, ECSM_REMR, ECSM_REAT and ECSM_REDRs, and the appropriate flag (RNCE) in the ECSM_ESR to be asserted.

Figure 8-10. RAM ECC Master Number Register (ECSM_REMR)

Table 8-12. ECSM_REMR Field Descriptions

Field	Description
0–3	Reserved.
4-7 REMR [0:3]	RAM ECC master number. Contains the XBAR bus master number of the faulting access of the last, properly-enabled RAM ECC event. The reset value of this field is undefined.

8.2.1.13 RAM ECC Attributes Register (ECSM_REAT)

The ECSM_REAT is an 8-bit register for capturing the XBAR bus master attributes of the last, properly-enabled ECC event in the RAM memory. Depending on the state of the ECSM_ECR, an ECC event in the RAM causes the address, attributes and data associated with the access to be loaded into the ECSM_REAR, ECSM_REMR, ECSM_REAT and ECSM_REDRs, and the appropriate flag (RNCE) in the ECSM_ESR to be asserted.

8.2.1.14 RAM ECC Data High Register (ECSM_REDRH)

The ECSM_REDRH and ECSM_REDRL are 32-bit registers for capturing the data associated with the last, properly-enabled ECC event in the RAM memory. Depending on the state of the ECSM_ECR, an ECC event in the RAM causes the address, attributes and data associated with the access to be loaded into the ECSM_REAR, ECSM_REMR, ECSM_REAT, and ECSM_REDRH and ECSM_REDRL, and the appropriate flag (RFNCE) in the ECSM_ESR to be asserted.

The data captured on a multi-bit non-correctable ECC error is undefined.

Figure 8-12. RAM ECC Data High Register (ECSM_REDRH)
Table 8-14. ECSM_REDRH Field Descriptions

Field	Description
0–31 REDH [0:31]	RAM ECC data. Contains the data associated with the faulting access of the last, properly-enabled RAM ECC event. The register contains the data value taken directly from the data bus. The reset value of this field is undefined.

8.2.1.15 RAM ECC Data Low Registers (ECSM_REDRL)

The ECSM_REDRL and ECSM_REDRL are 32-bit registers for capturing the data associated with the last, properly-enabled ECC event in the RAM memory. Depending on the state of the ECSM_ECR, an ECC event in the RAM causes the address, attributes and data associated with the access to be loaded into the ECSM_REAR, ECSM_REMR, ECSM_REAT, ECSM_REDRL, and ECSM_REDRL, and the appropriate flag (RFNCE) in the ECSM_ESR to be asserted.

The data captured on a multi-bit non-correctable ECC error is undefined.

Figure 8-13. RAM ECC Data Low Register (ECSM_REDRL)

Table 8-15. ECSM_REDRL Field Descriptions

Field	Description
0–31 REDL [0:31]	RAM ECC data. Contains the data associated with the faulting access of the last, properly-enabled RAM ECC event. The register contains the data value taken directly from the data bus. The reset value of this field is undefined.

8.3 Initialization and Application Information

To use the ECC mechanism for internal SRAM accesses, it is essential for the ECC check bits to be initialized after power on. All non-correctable ECC errors cause a data storage interrupt (IVOR2) regardless of whether non-correctable reporting is enabled. A data storage interrupt handler can determine:

- The destination asserted an error, the ESR[XTE] bit will be set.
- The address where the error occurred, using the data exception address register (DEAR).

However, details of the ECC error are not reported unless non-correctable reporting is enabled by setting bits ERNCR and EFNCR in the ECSM_ECR. When these bits are set and a non-correctable ECC error occurs, error information is recorded in other ECSM registers and an interrupt request is generated on vector 9 of the INTC. If properly enabled, this INTC vector 9 can cause an external interrupt (IVOR4) along with the data storage interrupt (IVOR2).

To avoid the external interrupt (IVOR4) being generated, the application enables non-correctable reporting in the ECSM, but does not enable that its interrupt be recognized. The INTC_PSR[PRI] value for the ECC error interrupt request is left at its reset value of 0. The 0 priority level is the lowest priority and is never recognized, resulting in only the data storage interrupt (IVOR2) being taken.

No changes since the Preliminary Version Rev 0 was released in January, 2006.

Chapter 9

Enhanced Direct Memory Access (eDMA)

9.1 Introduction

This chapter describes the enhanced Direct Memory Access (eDMA) Controller, a second-generation module capable of performing complex data transfers with minimal intervention from a host processor.

9.1.1 Overview

The enhanced direct memory access (eDMA) controller hardware microarchitecture includes a DMA engine which performs source and destination address calculations, and the actual data movement operations, along with SRAM-based local memory containing the transfer control descriptors (TCD) for the channels.

[Figure 9-1](#) is a block diagram of the eDMA module.

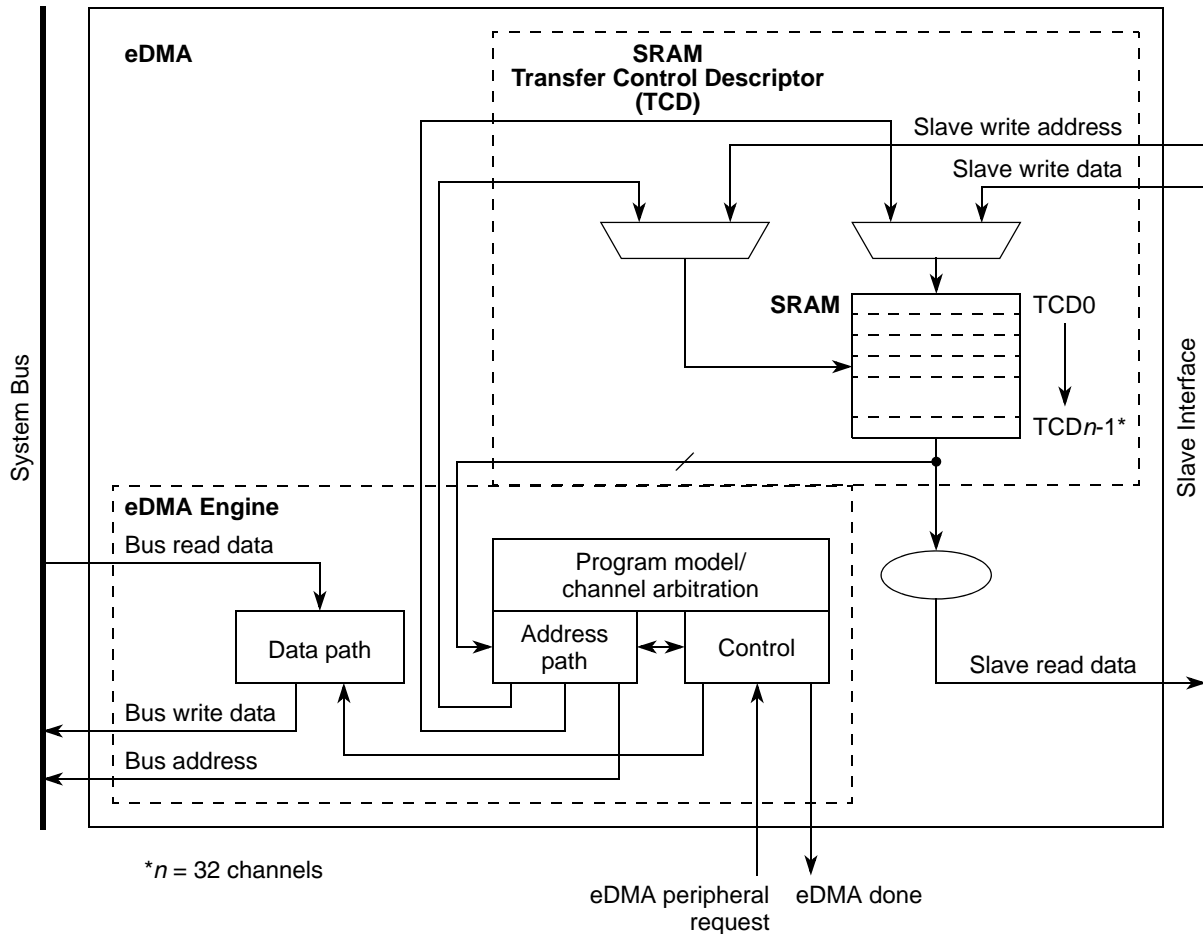

Figure 9-1. eDMA Block Diagram

9.1.2 Features

The eDMA is a highly-programmable data transfer engine, which has been optimized to minimize the required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known, and is *not* defined within the data packet itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
 - Programmable source, destination addresses, transfer size, plus support for enhanced addressing modes
- 32-channel implementation performs complex data transfers with minimal intervention from a host processor
 - 32 bytes of data registers, used as temporary storage to support burst transfers (refer to SSIZE bit)
 - Connections to the crossbar switch for bus mastering the data movement

- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
 - 32-byte TCD per channel stored in local memory
 - An inner data transfer loop defined by a minor byte transfer count
 - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
 - Explicit software initiation
 - Initiation via a channel-to-channel linking mechanism for continual transfers
 - Peripheral-paced hardware requests (one per channel)

NOTE

For all three methods, one activation per execution of the minor loop is required.

- Support for fixed-priority and round-robin channel arbitration
- Channel completion reported via optional interrupt requests
 - One interrupt per channel, optionally asserted at completion of major iteration count
 - Error terminations are enabled per channel, and logically summed together to form a single error interrupt.
- Support for scatter/gather DMA processing
- Any channel can be programmed so that it can be suspended by a higher priority channel's activation, before completion of a minor loop.

Throughout this chapter, n is used to reference the channel number. Additionally, data sizes are defined as byte (8-bit), halfword (16-bit), word (32-bit) and doubleword (64-bit).

9.1.3 Modes of Operation

9.1.3.1 Normal Mode

In normal mode, the eDMA is used to transfer data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.

9.1.3.2 Debug Mode

If enabled by EDMA_CR[EDBG] and the CPU enters debug mode, the eDMA does not grant a service request when the debug input signal is asserted. If the signal asserts during a data block transfer as described by a minor loop in the current active channel's TCD, the eDMA continues the operation until the minor loop completes.

9.2 Memory Map and Register Definition

9.2.1 Memory Map

The eDMA programming model is partitioned into two regions:

Region 1 defines control registers; Region 2 defines the local transfer control for the descriptor memory.

Table 9-1 is a 32-bit view of the eDMA memory map.

Table 9-1. eDMA 32-bit Memory Map

9.2.2 Register Descriptions

Read operations on reserved bits in a register return undefined data. Do not write operations to reserved bits. Writing to reserved bits in a register can generate errors. The maximum register bit-width for this device is 32-bits wide.

9.2.2.1 eDMA Control Register (EDMA_CR)

The 32-bit EDMA_CR defines the basic operating configuration of the eDMA.

The eDMA arbitrates channel service requests in two groups (0, 1) of 16 channels each. Group 0 contains channels 0-15, and group 1 contains channels 16-31.

Arbitration within a group can be configured to use either fixed-priority or round-robin. In fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The priorities are assigned by the channel priority registers. In round-robin arbitration mode, the channel priorities are ignored and the channels within each group are cycled through, from channel 15 down to channel 0, without regard to priority.

Refer to [Section 9.2.2.15, “eDMA Channel n Priority Registers \(EDMA_CPRn\).”](#)

The group priorities operate in a similar fashion. In group fixed-priority arbitration mode, channel service requests in the highest priority group are executed first where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the eDMA control register (EDMA_CR). All group priorities must have unique values prior to any channel service requests occur, otherwise a configuration error is reported. In group round-robin mode, the group priorities are ignored and the groups are cycled through, from group 1 down to group 0, without regard to priority.

Table 9-2. EDMA_CR Field Descriptions

Field	Description
0–20	Reserved.
21 GRP1PRI	Channel group 1 priority. Group 1 priority level when fixed-priority group arbitration is enabled.
22	Reserved.
23 GRP0PRI	Channel group 0 priority. Group 0 priority level when fixed-priority group arbitration is enabled.
24–27	Reserved.

Table 9-2. EDMA_CR Field Descriptions (continued)

Field	Description
28 ERGA	Enable round-robin group arbitration. 0 Fixed-priority arbitration is used for selection among the groups. 1 Round-robin arbitration is used for selection among the groups.
29 ERCA	Enable round-robin channel arbitration. 0 Fixed-priority arbitration is used for channel selection within each group. 1 Round-robin arbitration is used for channel selection within each group.
30 EDBG	Enable debug. 0 The assertion of the system debug control input is ignored. 1 The assertion of the system debug control input causes the eDMA to stall the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when either the system debug control input is negated or the EDBG bit is cleared.
31	Reserved.

9.2.2.2 eDMA Error Status Register (EDMA_ESR)

The EDMA_ESR provides information concerning the last recorded channel error. Channel errors can be caused by a configuration error (an illegal setting in the transfer control descriptor or an illegal priority register setting in fixed arbitration mode) or an error termination to a bus master read or write cycle.

A configuration error is caused when the starting source or destination address, source or destination offsets, minor loop byte count, and the transfer size represent an inconsistent state. The addresses and offsets must be aligned on 0-modulo-transfer_size boundaries, and the minor loop byte count must be a multiple of the source and destination transfer sizes. All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.

In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal within a group, or any group priority levels being equal among the groups. For either type of priority configuration error, the ERRCHN field is undefined. All channel priority levels within a group must be unique and all group priority levels among the groups must be unique when fixed arbitration mode is enabled.

If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary. If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCD.CITER.E_LINK bit does not equal the TCD.BITER.E_LINK bit. All configuration error conditions except scatter/gather and minor loop link error are reported as the channel is activated and assert an error interrupt request if enabled. When properly enabled, a scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is immediately stopped and the appropriate bus error flag is set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and minor loop byte count at the point of the fault. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to

switching to the next read sequence, the read sequence executes before the channel is terminated due to the destination bus error.

The occurrence of any type of error causes the eDMA engine to stop the active channel, and the appropriate channel bit in the eDMA error register to be asserted. At the same time, the details of the error condition are loaded into the EDMA_ESR. The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are *not* affected when an error is detected. After the error status has been updated, the eDMA engine continues to operate by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

Figure 9-3. eDMA Error Status Register (EDMA_ESR)

Table 9-3. EDMA_ESR Field Descriptions

Field	Description
0 VLD	Logical OR of all EDMA_ERH and EDMA_ERL status bits. 0 No EDMA_ER bits are set. 1 At least one EDMA_ER bit is set indicating a valid error exists that has not been cleared.
1–15	Reserved.
16 GPE	Group priority error. 0 No group priority error. 1 The last recorded error was a configuration error among the group priorities indicating not all group priorities are unique.
17 CPE	Channel priority error. 0 No channel priority error. 1 The last recorded error was a configuration error in the channel priorities within a group, indicating not all channel priorities within a group are unique.
18–23 ERRCHN[0:5]	Error channel number. Channel number of the last recorded error (excluding GPE and CPE errors). Note: Do not rely on the number in the ERRCHN field for group and channel priority errors. Group and channel priority errors need to be resolved by inspection. The application code must interrogate the priority registers to find groups or channels with duplicate priority level.

Table 9-3. EDMA_ESR Field Descriptions (continued)

Field	Description
24 SAE	Source address error. 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCD.SADDR field, indicating TCD.SADDR is inconsistent with TCD.SSIZE.
25 SOE	Source offset error. 0 No source offset configuration error. 1 The last recorded error was a configuration error detected in the TCD.SOFF field, indicating TCD.SOFF is inconsistent with TCD.SSIZE.
26 DAE	Destination address error. 0 No destination address configuration error. 1 The last recorded error was a configuration error detected in the TCD.DADDR field, indicating TCD.DADDR is inconsistent with TCD.DSIZE.
27 DOE	Destination offset error. 0 No destination offset configuration error. 1 The last recorded error was a configuration error detected in the TCD.DOFF field, indicating TCD.DOFF is inconsistent with TCD.DSIZE.
28 NCE	NBYTES/CITER configuration error. 0 No NBYTES/CITER configuration error. 1 The last recorded error was a configuration error detected in the TCD.NBYTES or TCD.CITER fields, indicating the following conditions exist: <ul style="list-style-type: none"> • TCD.NBYTES is not a multiple of TCD.SSIZE and TCD.DSIZE, or • TCD.CITER is equal to zero, or • TCD.CITER.E_LINK is not equal to TCD.BITER.E_LINK.
29 SGE	Scatter/gather configuration error. 0 No scatter/gather configuration error. 1 The last recorded error was a configuration error detected in the TCD.DLAST_SGA field, indicating TCD.DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCD.E_SG is enabled.
30 SBE	Source bus error. 0 No source bus error. 1 The last recorded error was a bus error on a source read.
31 DBE	Destination bus error. 0 No destination bus error. 1 The last recorded error was a bus error on a destination write.

9.2.2.3 eDMA Enable Request Register (EDMA_ERQRL)

The EDMA_ERQRL provides a bit map for the 32 implemented channels to enable the request signal for each channel. EDMA_ERQRL maps to channels 31–0.

The state of any given channel enable is directly affected by writes to this register; the state is also affected by writes to the EDMA_SERQR and EDMA_CERQR. The EDMA_CERQR and EDMA_SERQR are provided so that the request enable for a *single* channel can easily be modified without the need to perform a read-modify-write sequence to the EDMA_ERQRL.

Both the DMA request input signal and this enable request flag must be asserted before a channel’s hardware service request is accepted. The state of the eDMA enable request flag does *not* affect a channel service request made explicitly through software or a linked channel request.

Figure 9-4. eDMA Enable Request Low Register (EDMA_ERQRL)

Table 9-4. EDMA_ERQRL Field Descriptions

Field	Description
0–31 ERQ _n	Enable DMA hardware service request <i>n</i> . 0 The DMA request signal for channel <i>n</i> is disabled. 1 The DMA request signal for channel <i>n</i> is enabled.

As a given channel completes the processing of its major iteration count, there is a flag in the transfer control descriptor that can affect the ending state of the EDMA_ERQR bit for that channel. If the TCD.D_REQ bit is set, then the corresponding EDMA_ERQR bit is cleared after the major loop is complete, disabling the DMA hardware request. Otherwise if the D_REQ bit is cleared, the state of the EDMA_ERQR bit is unaffected.

9.2.2.4 eDMA Enable Error Interrupt Register (EDMA_EEIRL)

The EDMA_EEIRL provides a bit map for the 32 channels to enable the error interrupt signal for each channel. EDMA_EEIRL maps to channels 31-0.

The state of any given channel’s error interrupt enable is directly affected by writes to these registers; it is also affected by writes to the EDMA_SEEIR and EDMA_CEEIR. The EDMA_SEEIR and EDMA_CEEIR are provided so that the error interrupt enable for a *single* channel can easily be modified without the need to perform a read-modify-write sequence to the EDMA_EEIRL.

Both the DMA error indicator and this error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted.

Address: Base + 0x0014

Access: User R/W

Figure 9-5. eDMA Enable Error Interrupt Low Register (EDMA_EEIRL)

Field	Description
0–31 EEIn	Enable error interrupt <i>n</i> . 0 The error signal for channel <i>n</i> does not generate an error interrupt. 1 The assertion of the error signal for channel <i>n</i> generate an error interrupt request.

9.2.2.5 eDMA Set Enable Request Register (EDMA_SERQR)

The EDMA_SERQR provides a simple memory-mapped mechanism to set a given bit in the EDMA_ERQRL to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the EDMA_ERQRL to be set. Setting bit 1 (SERQ_{*n*}) provides a global set function, forcing the entire contents of EDMA_ERQRL to be asserted. Reads of this register return all zeroes.

Address: Base + 0x0018

Access: User write-only

Figure 9-6. eDMA Set Enable Request Register (EDMA_SERQR)

9.2.2.6 eDMA Clear Enable Request Register (EDMA_CERQR)

The EDMA_CERQR provides a simple memory-mapped mechanism to clear a given bit in the EDMA_ERQRL to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the EDMA_ERQRL to be cleared. Setting bit 1 (CERQ n) provides a global clear function, forcing the entire contents of the EDMA_ERQRL to be zeroed, disabling all DMA request inputs. Reads of this register return all zeroes.

0	Reserved.
1–7 CERQ[0:6]	Clear enable request. 0–31 Clear corresponding bit in EDMA_ERQRL 32–63 Reserved 64–127 Clear all bits in EDMA_ERQRH and EDMA_ERQRL Note: Bit 2 (CERQ1) is not used.

9.2.2.7 eDMA Set Enable Error Interrupt Register (EDMA_SEEIR)

The EDMA_SEEIR provides a simple memory-mapped mechanism to set a given bit in the EDMA_EEIRL to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EDMA_EEIRL to be set. Setting bit 1 (SEEI n) provides a global set function, forcing the entire contents of EDMA_EEIRL to be asserted. Reads of this register return all zeroes.

Figure 9-8. eDMA Set Enable Error Interrupt Register (EDMA_SEEIR)

Field	Description
0	Reserved.
1–7 SEEI[0:6]	Set enable error interrupt. 0–31 Set corresponding bit in EDMA_EIRRL 32–63 Reserved 64–127 Set all bits in EDMA_EEIRH or EDMA_EEIRL Note: Bit 2 (SEEI1) is not used.

9.2.2.8 eDMA Clear Enable Error Interrupt Register (EDMA_CEEIR)

The EDMA_CEEIR provides a simple memory-mapped mechanism to clear a given bit in the EDMA_EEIRL to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EDMA_EEIRL to be cleared. Setting bit 1 (CEEIn) provides a global clear function, forcing the entire contents of the EDMA_EEIRL to be zeroed, disabling error interrupts for all channels. Reads of this register return all zeroes.

Figure 9-9. eDMA Clear Enable Error Interrupt Register (EDMA_CEEIR)

Table 9-9. EDMA_CEEIR Field Descriptions

Field	Description
0	Reserved.
1–7 CEEI[0:6]	Clear enable error interrupt. 0–31 Clear corresponding bit in EDMA_EEIRL 32–63 Reserved 64–127 Clear all bits in EDMA_EEIRH or EDMA_EEIRL Note: Bit 2 (CEEI1) is not used.

9.2.2.9 eDMA Clear Interrupt Request Register (EDMA_CIRQR)

The EDMA_CIRQR provides a simple memory-mapped mechanism to clear a given bit in the EDMA_IRQRL to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the EDMA_IRQRL to be cleared. Setting bit 1 (CINT_n) provides a global clear function, forcing the entire contents of the EDMA_IRQRL to be zeroed, disabling all DMA interrupt requests. Reads of this register return all zeroes.

Figure 9-10. eDMA Clear Interrupt Request (EDMA_CIRQR)

Table 9-10. EDMA_CIRQR Field Descriptions

Field	Description
0	Reserved.
1–7 CINT[0:6]	Clear interrupt request. 0–31 Clear corresponding bit in EDMA_IRQRL 32–63 Reserved 64–127 Clear all bits in EDMA_IRQRH or EDMA_IRQRL Note: Bit 2 (CINT1) is not used.

9.2.2.10 eDMA Clear Error Register (EDMA_CER)

The EDMA_CER provides a simple memory-mapped mechanism to clear a given bit in the EDMA_ERL to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the EDMA_ERL to be cleared. Setting bit 1 (CERR_n) provides a global clear function, forcing the entire contents of the EDMA_ERL to be zeroed, clearing all channel error indicators. Reads of this register return all zeroes.

Figure 9-11. eDMA Clear Error Register (EDMA_CER)

Table 9-11. EDMA_CER Field Descriptions

Field	Description
0	Reserved.
1–7 CERR[0:6]	Clear error indicator. 0–31 Clear corresponding bit in EDMA_ERL 32–63 Reserved 64–127 Clear all bits in EDMA_ERH or EDMA_ERL Note: Bit 2 (CERR1) is not used.

9.2.2.11 eDMA Set START Bit Register (EDMA_SSBR)

The EDMA_SSBR provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting bit 1 (SSB_n) provides a global set function, forcing all START bits to be set. Reads of this register return all zeroes.

Figure 9-12. eDMA Set START Bit Register (EDMA_SSBR)

Table 9-12. EDMA_SSBR Field Descriptions

Field	Description
0	Reserved.
1–7 SSB[0:6]	Set START bit (channel service request). 0–31 Set the corresponding channel's TCD START bit 32–63 Reserved 64–127 Set all TCD START bits Note: Bit 2 (SSB1) is not used.

9.2.2.12 eDMA Clear DONE Status Bit Register (EDMA_CDSBR)

The EDMA_CDSBR provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting bit 1 (CDSB n) provides a global clear function, forcing all DONE bits to be cleared.

Figure 9-13. eDMA Clear DONE Status Bit Register (EDMA_CDSBR)

Table 9-13. EDMA_CDSBR Field Descriptions

Field	Description
0	Reserved.
1–7 CDSB[0:6]	Clear DONE status bit. 0–31 Clear the corresponding channel's DONE bit 32–63 Reserved 64–127 Clear all TCD DONE bits Note: Bit 2 (CDSB1) is not used.

9.2.2.13 eDMA Interrupt Request Register (EDMA_IRQRL)

The EDMA_IRQRL provide a bit map for the 32 channels signaling the presence of an interrupt request for each channel. EDMA_IRQRL maps to channels 31–0.

The eDMA engine signals the occurrence of a programmed interrupt upon the completion of a data transfer as defined in the transfer control descriptor by setting the appropriate bit in this register. The outputs of this register are directly routed to the interrupt controller (INTC). During the execution of the interrupt service routine associated with any given channel, it is software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the EDMA_CIRQR in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the EDMA_CIRQR. On writes to the EDMA_IRQRL, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The EDMA_CIRQR is provided so the interrupt request for a *single* channel can easily be cleared without the need to perform a read-modify-write sequence to the EDMA_IRQRL.

Field	Description
0–31 INT n	eDMA interrupt request n . 0 The interrupt request for channel n is cleared. 1 The interrupt request for channel n is active.

9.2.2.14 eDMA Error Register (EDMA_ERL)

The EDMA_ERL provides a bit map for the 32 channels signaling the presence of an error for each channel. EDMA_ERL maps to channels 31-0.

The eDMA engine signals the occurrence of a error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EDMA_EEIR, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests which is then routed to the interrupt controller. During the execution of the interrupt service routine associated with any DMA errors, it is software’s responsibility to clear the appropriate bit, negating the error interrupt request. Typically, a write to the EDMA_CER in the interrupt service routine is used for this purpose. Recall the normal DMA channel completion indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are *not* affected when an error is detected.

The contents of this register can also be polled and a non-zero value indicates the presence of a channel error, regardless of the state of the EDMA_EEIR. The EDMA_ESR[VLD] bit is a logical OR of all bits in this register and it provides a single bit indication of any errors. The state of any given channel’s error indicators is affected by writes to this register; it is also affected by writes to the EDMA_CER. On writes to EDMA_ERL, a 1 in any bit position clears the corresponding channel’s error status. A 0 in any bit position has no affect on the corresponding channel’s current error status. The EDMA_CER is provided so the error indicator for a *single* channel can easily be cleared.

0–31 HRS _n	DMA Hardware Request Status 0 A hardware service request for channel <i>n</i> is not present. 1 A hardware service request for channel <i>n</i> is present. Note: The hardware request status reflects the state of the request as seen by the arbitration logic. Therefore, this status is affected by the EDMA_ERQRL[ERQ _n] bit.

9.2.2.15 eDMA Channel *n* Priority Registers (EDMA_CPR*n*)

When the fixed-priority channel arbitration mode is enabled (EDMA_CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; that is, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. If software chooses to modify channel priority values, then the software must ensure that the channel priorities contain unique values, otherwise a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the EDMA_CPR*n* register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the EDMA_CPR*n* registers. The group priority is assigned in the EDMA_CR.

Refer to [Figure 9-2](#) and [Table 9-2](#) for the EDMA_CR definition.

Channel preemption is enabled on a per-channel basis by setting the ECP bit in the EDMA_CPR*n* register. Channel preemption allows the executing channel's data transfers to be temporarily suspended in favor of starting a higher priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption (attempting to preempt a preempting channel) is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is only available when fixed arbitration is selected for both group and channel arbitration modes.

Address: Base + 0x100 + n				Access: User R/W				
	0	1	2 3	4	5 6 7			
R	ECP	0	GRPPRI	CHPRI				
W								
Reset	0	0		— ¹				

¹ The reset value for the group and channel priority fields, GRPPRI[0–1] and CHPRI[0–3] is the channel number for the priority register;
 EDMA_CPR31[GRPPRI] = 0b01 and
 EDMA_CPR31[CHPRI] = 0b1111.

Figure 9-17. eDMA Channel *n* Priority Register (EDMA_CPR*n*)

The following table describes the fields in the eDMA channel n priority register:

Table 9-17. EDMA_CPR n Field Descriptions

Field	Description
0 ECP	Enable channel preemption. 0 Channel n cannot be suspended by a higher priority channel's service request. 1 Channel n can be temporarily suspended by the service request of a higher priority channel.
1	Reserved.
2–3 GRPPRI[0:1]	Channel n current group priority. Group priority assigned to this channel group when fixed-priority arbitration is enabled. These two bits are read only; writes are ignored. The reset value for the group priority fields, is equal to the corresponding channel number for each priority register; that is, EDMA_CPR31[GRPPRI] = 0b01.
4–7 CHPRI[0:3]	Channel n arbitration priority. Channel priority when fixed-priority arbitration is enabled. The reset value for the channel priority fields CHPRI[0–3], is equal to the corresponding channel number for each priority register; that is, EDMA_CPR31[CHPRI] = 0b1111.

9.2.2.16 Transfer Control Descriptor (TCD)

Each channel requires a 256-bit transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1,... channel 31. The definitions of the TCD are presented as 23 variable-length fields.

Table 9-18 defines the fields of the basic TCD structure.

Table 9-18. TCD n 32-bit Memory Structure

eDMA Bit Offset	Bit Length	TCD n Field Name	TCD n Abbreviation	Word #
0x1000 + (32 x n) + 0	32	Source address	SADDR	Word 0
0x1000 + (32 x n) + 32	5	Source address modulo	SMOD	Word 1
0x1000 + (32 x n) + 37	3	Source data transfer size	SSIZE	
0x1000 + (32 x n) + 40	5	Destination address modulo	DMOD	
0x1000 + (32 x n) + 45	3	Destination data transfer size	DSIZE	
0x1000 + (32 x n) + 48	16	Signed Source Address Offset	SOFF	
0x1000 + (32 x n) + 64	32	Inner minor byte count	NBYTES	Word 2
0x1000 + (32 x n) + 96	32	Last Source Address Adjustment	SLAST	Word 3
0x1000 + (32 x n) + 128	32	Destination Address	DADDR	Word 4
0x1000 + (32 x n) + 160	1	Channel-to-channel Linking on Minor Loop Complete	CITER.E_LINK	Word 5
0x1000 + (32 x n) + 161	6	Current Major Iteration Count or Link Channel Number	CITER or CITER.LINKCH	
0x1000 + (32 x n) + 167	9	Current Major Iteration Count	CITER	
0x1000 + (32 x n) + 176	16	Destination Address Offset (Signed)	DOFF	

Table 9-18. TCD_n 32-bit Memory Structure (continued)

eDMA Bit Offset	Bit Length	TCD _n Field Name	TCD _n Abbreviation	Word #
0x1000 + (32 x n) + 192	32	Last Destination Address Adjustment / Scatter Gather Address	DLAST_SGA	Word 6
0x1000 + (32 x n) + 224	1	Channel-to-channel Linking on Minor Loop Complete	BITER.E_LINK	Word 7
0x1000 + (32 x n) + 225	6	Starting Major Iteration Count or Link Channel Number	BITER or BITER.LINKCH	
0x1000 + (32 x n) + 231	9	Starting Major Iteration Count	BITER	
0x1000 + (32 x n) + 240	2	Bandwidth Control	BWC	
0x1000 + (32 x n) + 242	6	Link Channel Number	MAJOR.LINKCH	
0x1000 + (32 x n) + 248	1	Channel Done	DONE	
0x1000 + (32 x n) + 249	1	Channel Active	ACTIVE	
0x1000 + (32 x n) + 250	1	Channel-to-channel Linking on Major Loop Complete	MAJOR.E_LINK	
0x1000 + (32 x n) + 251	1	Enable Scatter/Gather Processing	E_SG	
0x1000 + (32 x n) + 252	1	Disable Request	D_REQ	
0x1000 + (32 x n) + 253	1	Channel Interrupt Enable When Current Major Iteration Count is Half Complete	INT_HALF	
0x1000 + (32 x n) + 254	1	Channel Interrupt Enable When Current Major Iteration Count Complete	INT_MAJ	
0x1000 + (32 x n) + 255	1	Channel Start	START

Figure 9-18. TCD Structure

- ¹ If channel linking on minor link completion is disabled, TCD bits [161:175] are used to form a 15-bit CITER field; if channel-to-channel linking is enabled, CITER becomes a 9-bit field.
- ² If channel linking on minor link completion is disabled, TCD bits [225:239] are used to form a 15-bit BITER field; if channel-to-channel linking is enabled, BITER becomes a 9-bit field.

NOTE

The TCD structures for the eDMA channels shown in Figure 9-18 are implemented in internal SRAM. These structures are not initialized at reset. Therefore, all channel TCD parameters must be initialized by the application code before activating that channel.

The following table gives a detailed description of the TCN_n fields:

Table 9-19. TCD_n Field Descriptions

Bits Word Offset [n:n]	Field Name	Description
0–31 0x0 [0:31]	SADDR [0:31]	Source address. Memory address pointing to the source data. Word 0x0, bits 0–31.
32–36 0x4 [0:4]	SMOD [0:4]	Source address modulo. 0 Source address modulo feature is disabled. not 0 This value defines a specific address range which is specified to be either the value after SADDR + SOFF calculation is performed or the original register value. The setting of this field provides the ability to easily implement a circular data queue. For data queues requiring power-of-2 “size” bytes, start the queue at a 0-modulo-size address and set the SMOD field to the value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For this circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
37–39 0x4 [5:7]	SSIZE [0:2]	Source data transfer size. 000 8-bit 001 16-bit 010 32-bit 011 64-bit 100 32-bit 101 32-byte burst (64-bit x 4) 110 Reserved 111 Reserved The attempted specification of a ‘reserved’ encoding causes a configuration error.
40–44 0x4 [8:12]	DMOD [0:4]	Destination address modulo. Refer to the SMOD[0:5] definition.
45–47 0x4 [13:15]	DSIZE [0:2]	Destination data transfer size. Refer to the SSIZE[0:2] definition.
48–63 0x4 [16:31]	SOFF [0:15]	Source address signed offset. Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.
64–95 0x8 [0:31]	NBYTES [0:31]	Inner “minor” byte transfer count. Number of bytes to be transferred in each service request of the channel. As a channel is activated, the contents of the appropriate TCD is loaded into the eDMA engine, and the appropriate reads and writes performed until the complete byte transfer count has been transferred. This is an indivisible operation and cannot be stalled or halted. Once the minor count is exhausted, the current values of the SADDR and DADDR are written back into the local memory, the major iteration count is decremented and restored to the local memory. If the major iteration count is completed, additional processing is performed. Note: The NBYTES value of 0x0000_0000 is interpreted as 0x1_0000_0000, thus specifying a four GB transfer.
96–127 0xC [0:31]	SLAST [0:31]	Last source address adjustment. Adjustment value added to the source address at the completion of the outer major iteration count. This value can be applied to “restore” the source address to the initial value, or adjust the address to reference the next data structure.

Table 9-19. TCD_n Field Descriptions (continued)

Bits Word Offset [n:n]	Field Name	Description
128–159 0x10 [0:31]	DADDR [0:31]	Destination address. Memory address pointing to the destination data.
160 0x14 [0]	CITER.E_LINK	<p>Enable channel-to-channel linking on minor loop completion. As the channel completes the inner minor loop, this flag enables the linking to another channel, defined by CITER.LINKCH[0:5]. The link target channel initiates a channel service request via an internal mechanism that sets the TCD.START bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJOR.E_LINK channel linking.</p> <p>0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.</p> <p>Note: This bit must be equal to the BITER.E_LINK bit otherwise a configuration error is reported.</p>
161–166 0x14 [1:6]	CITER [0:5] or CITER.LINKCH [0:5]	<p>Current “major” iteration count or link channel number.</p> <p>If channel-to-channel linking is disabled (TCD.CITER.E_LINK = 0), then</p> <ul style="list-style-type: none"> No channel-to-channel linking (or chaining) is performed after the inner minor loop is exhausted. TCD bits [161:175] are used to form a 15-bit CITER field. <p>otherwise</p> <ul style="list-style-type: none"> After the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by CITER.LINKCH[0:5] by setting that channel's TCD.START bit.
167–175 0x14 [7:15]	CITER [6:14]	<p>Current “major” iteration count. This 9 or 15-bit count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (for example, final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field.</p> <p>Note: When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.</p> <p>Note: If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.</p>
176–191 0x14 [16:31]	DOFF [0:15]	Destination address signed offset. Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed.
192–223 0x18 [0:31]	DLAST_SGA [0:31]	<p>Last destination address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather).</p> <p>If scatter/gather processing for the channel is disabled (TCD.E_SG = 0) then</p> <ul style="list-style-type: none"> Adjustment value added to the destination address at the completion of the outer major iteration count. <p>This value can be applied to “restore” the destination address to the initial value, or adjust the address to reference the next data structure.</p> <p>Otherwise</p> <ul style="list-style-type: none"> This address points to the beginning of a 0-modulo-32 byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32 byte, otherwise a configuration error is reported.

Table 9-19. TCD_n Field Descriptions (continued)

Bits Word Offset [n:n]	Field Name	Description
224 0x1C [0]	BITER.E_LINK	<p>Enables channel-to-channel linking on minor loop complete. As the channel completes the inner minor loop, this flag enables the linking to another channel, defined by BITER.LINKCH[0:5]. The link target channel initiates a channel service request via an internal mechanism that sets the TCD.START bit of the specified channel. If channel linking is disabled, the BITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJOR.E_LINK channel linking.</p> <p>0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.</p> <p>Note: When the TCD is first loaded by software, this field must be set equal to the corresponding CITER field, otherwise a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field.</p>
225–230 0x1C [1:6]	BITER [0:5] or BITER.LINKCH [0:5]	<p>Beginning or starting “major” iteration count or link channel number. If channel-to-channel linking is disabled (TCD.BITER.E_LINK = 0), then</p> <ul style="list-style-type: none"> No channel-to-channel linking (or chaining) is performed after the inner minor loop is exhausted. TCD bits [225:239] are used to form a 15-bit BITER field. <p>Otherwise</p> <ul style="list-style-type: none"> After the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel, defined by BITER.LINKCH[0:5], by setting that channel’s TCD.START bit. <p>Note: When the TCD is first loaded by software, this field must be set equal to the corresponding CITER field, otherwise a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field.</p>
231–239 0x1C [7:15]	BITER [6:14]	<p>Beginning or starting major iteration count. As the transfer control descriptor is first loaded by software, this field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field.</p> <p>Note: If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.</p>
240–241 0x1C [16:17]	BWC [0:1]	<p>Bandwidth control. This two-bit field provides a mechanism to effectively throttle the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the inner minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the system bus crossbar switch (XBAR).</p> <p>To minimize start-up latency, bandwidth control stalls are suppressed for the first two system bus cycles and after the last write of each minor loop.</p> <p>00 No eDMA engine stalls 01 Reserved 10 eDMA engine stalls for four cycles after each r/w 11 eDMA engine stalls for eight cycles after each r/w</p>

Table 9-19. TCD_n Field Descriptions (continued)

Bits Word Offset [n:n]	Field Name	Description
242–247 0x1C [18:23]	MAJOR.LINKCH [0:5]	Link channel number. If channel-to-channel linking on major loop complete is disabled (TCD.MAJOR.E_LINK = 0) then: <ul style="list-style-type: none"> No channel-to-channel linking (or chaining) is performed after the outer major loop counter is exhausted. Otherwise <ul style="list-style-type: none"> After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by MAJOR.LINKCH[0:5] by setting that channel's TCD.START bit.
248 0x1C [24]	DONE	Channel done. This flag indicates the eDMA has completed the outer major loop. It is set by the eDMA engine as the CITER count reaches zero; it is cleared by software or hardware when the channel is activated (when the channel has begun to be processed by the eDMA engine, not when the first data transfer occurs). <p>Note: This bit must be cleared to write the MAJOR.E_LINK or E_SG bits.</p>
249 0x1C [25]	ACTIVE	Channel active. This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA engine as the inner minor loop completes or if any error condition is detected.
250 0x1C [26]	MAJOR.E_LINK	Enable channel-to-channel linking on major loop completion. As the channel completes the outer major loop, this flag enables the linking to another channel, defined by MAJOR.LINKCH[0:5]. The link target channel initiates a channel service request via an internal mechanism that sets the TCD.START bit of the specified channel. <p>NOTE: To support the dynamic linking coherency model, this field is forced to zero when written to while the TCD.DONE bit is set.</p> 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
251 0x1C [27]	E_SG	Enable scatter/gather processing. As the channel completes the outer major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLAST_SGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure which is loaded as the transfer control descriptor into the local memory. <p>NOTE: To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCD.DONE bit is set.</p> 0 The current channel's TCD is "normal" format. 1 The current channel's TCD specifies a scatter gather format. The DLAST_SGA field provides a memory pointer to the next TCD to be loaded into this channel after the outer major loop completes its execution.
252 0x1C [28]	D_REQ	Disable hardware request. If this flag is set, the eDMA hardware automatically clears the corresponding EDMA_ERQL bit when the current major iteration count reaches zero. 0 The channel's EDMA_ERQL bit is not affected. 1 The channel's EDMA_ERQL bit is cleared when the outer major loop is complete.

Table 9-19. TCDn Field Descriptions (continued)

Bits Word Offset [n:n]	Field Name	Description
253 0x1C [29]	INT_HALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the bit in the EDMA_ERQL when the current major iteration count reaches the halfway point. The eDMA engine performs the compare (CITER == (BITER >> 1)). This halfway point interrupt request supports double-buffered (aka ping-pong) schemes, or where the processor needs an early indication of the data transfer's progress during data movement. CITER = BITER = 1 with INT_HALF enabled generates an interrupt as it satisfies the equation (CITER == (BITER >> 1)) after a single activation. 0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled.
254 0x1C [30]	INT_MAJ	Enable an interrupt when major iteration count completes. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the EDMA_ERQL when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled. 1 The end-of-major loop interrupt is enabled.
255 0x1C [31]	START	Channel start. If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. 0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request.

9.3 Functional Description

This section provides an overview of the microarchitecture and functional operation of the eDMA module.

9.3.1 eDMA Microarchitecture

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory. Additionally, the eDMA engine is further partitioned into four submodules, which are detailed below.

- eDMA engine
 - Address path: This module implements registered versions of two channel transfer control descriptors: channel ‘x’ and channel ‘y,’ and is responsible for all the master bus address calculations. All the implemented channels provide the exact same functionality. This hardware structure allows the data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel service request is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed unless preempted by a higher priority channel. This capability provides a mechanism (optionally enabled by EDMA_CPRn[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.

When any other channel is activated, the contents of its transfer control descriptor is read from the local memory and loaded into the registers of the other address path channel{x,y}. After the inner minor loop completes execution, the address path hardware writes the new values for the TCDn.{SADDR, DADDR, CITER} back into the local memory. If the major iteration

count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCDn.CITER field, and a possible fetch of the next TCD n from memory as part of a scatter/gather operation.

- Data path: This module implements the actual bus master read/write datapath. It includes 32 bytes of register storage (matching the maximum transfer size) and the necessary mux logic to support any required data alignment. The system read data bus is the primary input, and the system write data bus is the primary output.

The address and data path modules directly support the 2-stage pipelined system bus. The address path module represents the 1st stage of the bus pipeline (the address phase), while the data path module implements the 2nd stage of the pipeline (the data phase).

- Program model/channel arbitration: This module implements the first section of eDMA's programming model as well as the channel arbitration logic. The programming model registers are connected to the slave bus (not shown). The eDMA peripheral request inputs and eDMA interrupt request outputs are also connected to this module (via the Control logic).
- Control: This module provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read, destination write operations until the number of bytes specified in the inner 'minor loop' byte count has been moved.

A minor loop interaction is defined as the number of bytes to transfer (n bytes) divided by the transfer size. Transfer size is defined as the following:

if (SSIZE < DSIZE)

transfer size = destination transfer size (# of bytes)

else

transfer size = source transfer size (# of bytes)

Minor loop TCD variables are SOFF, SMOD, DOFF, DMOD, NBYTES, SADDR, DADDR, BWC, ACTIVE, AND START. Major loop TCD variables are DLAST, SLAST, CITER, BITER, DONE, D_REQ, INT_MAJ, MAJOR_LNKCH, and INT_HALF.

For descriptors where the sizes are not equal, multiple access of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

- TCD local memory
 - Memory controller: This logic implements the required dual-ported controller, handling accesses from both the eDMA engine as well as references from the slave bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the slave transaction is stalled. The hooks to a BIST controller for the local TCD memory are included in this module.
 - Memory array: The TCD is implemented using a single-ported, synchronous compiled RAM memory array.

9.3.2 eDMA Basic Data Flow

The basic flow of a data transfer can be partitioned into three segments. As shown in Figure 9-19, the first segment involves the channel service request. In the diagram, this example uses the assertion of the eDMA peripheral request signal to request service for channel n . Channel service request via software and the TCDn.START bit follows the same basic flow as an eDMA peripheral request. The eDMA peripheral request input signal is registered internally and then routed to through the eDMA engine, first through the control module, then into the program model/channel arbitration module. In the next cycle, the channel arbitration is performed, either using the fixed-priority or round-robin algorithm. After the arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the TCD local memory. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel{x,y} registers. The TCD memory is organized 64-bits in width to minimize the time needed to fetch the activated channel's descriptor and load it into the eDMA engine address path channel{x,y} registers.

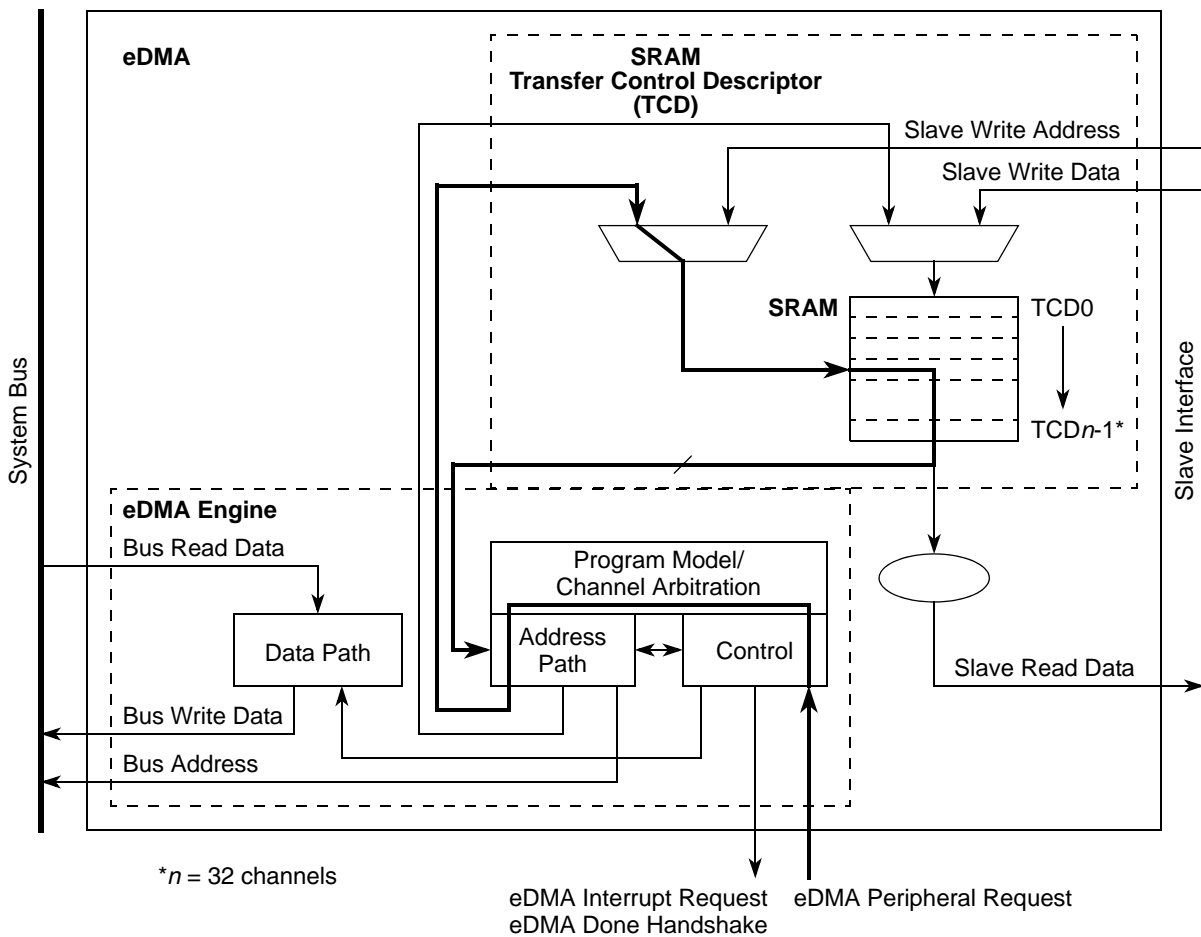

Figure 9-19. eDMA Operation, Part 1

In the second part of the basic data flow as shown in Figure 9-20, the modules associated with the data transfer (address path, data path and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path module until it is gated onto the system bus during the destination write.

This source read/destination write processing continues until the inner minor byte count has been transferred. The eDMA Done Handshake signal is asserted at the end of the minor byte count transfer.

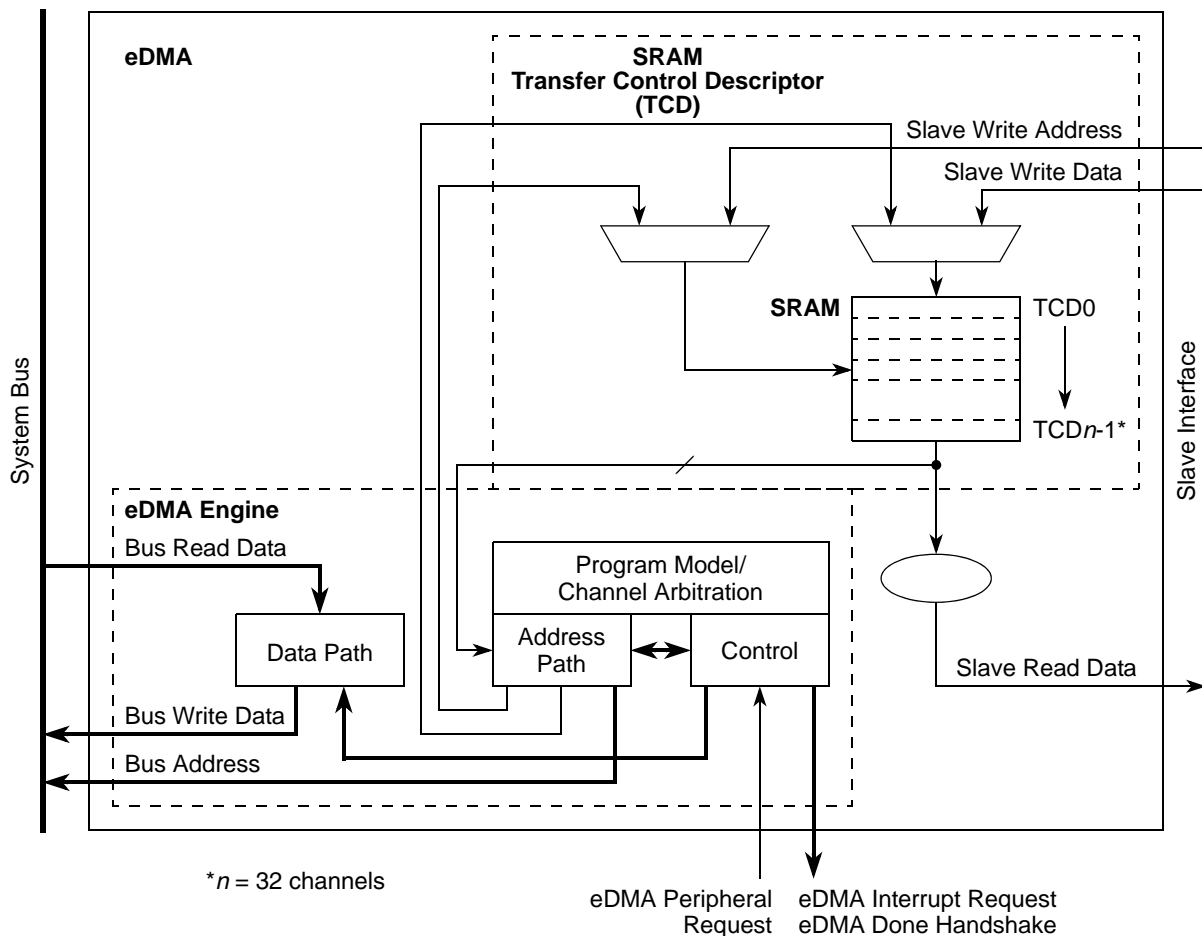

Figure 9-20. eDMA Operation, Part 2

After the inner minor byte count has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the channel's TCD: for example., SADDR, DADDR, CITER. If the outer major iteration count is exhausted, then there are additional operations which are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Additionally, assertion of an optional interrupt request occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor. The updates to the TCD memory and the assertion of an interrupt request are shown in [Figure 9-21](#).

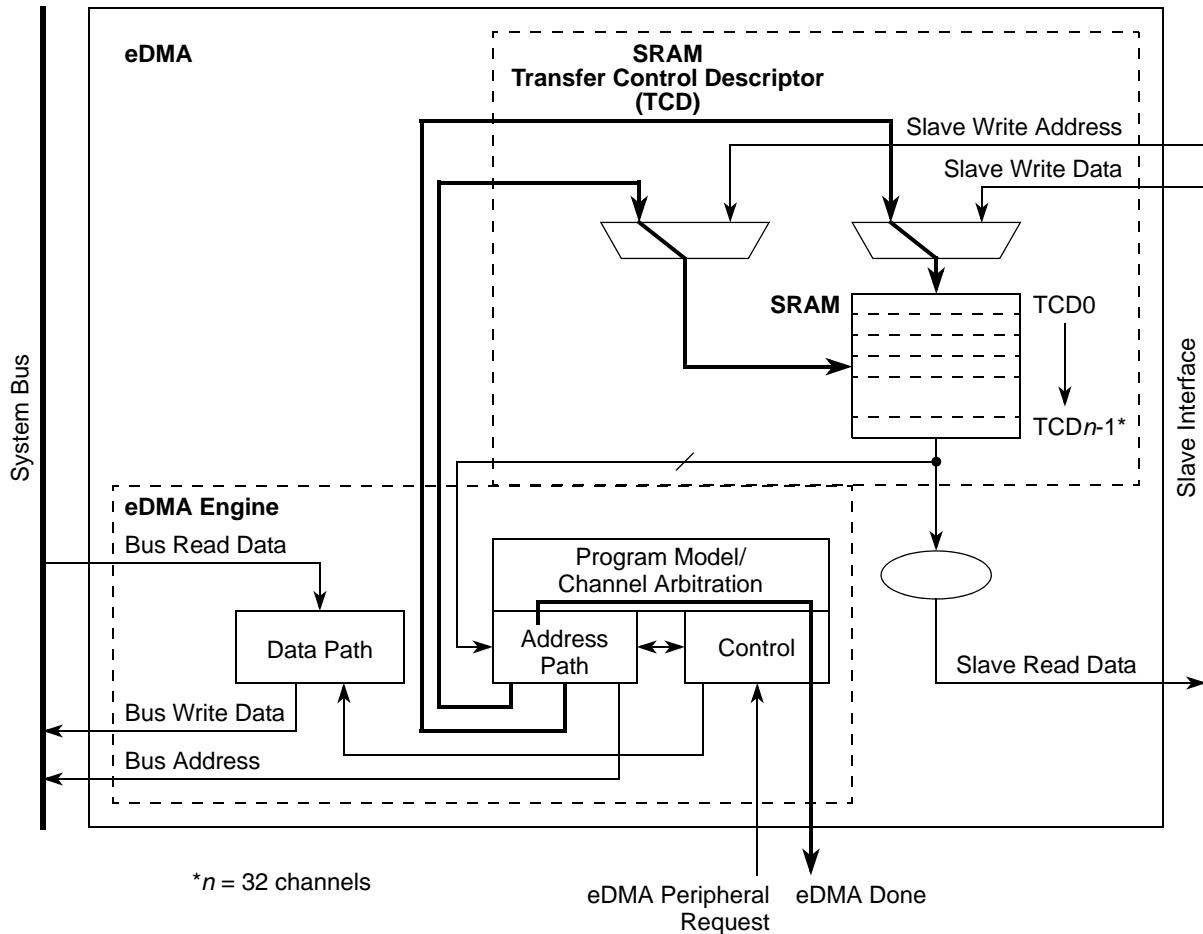

Figure 9-21. eDMA Operation, Part 3

9.3.3 eDMA Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics. In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces. In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more useful metric. In this environment, the speed of the source and destination address spaces remains important, but the microarchitecture of the eDMA also factors significantly into the resulting metric.

The peak transfer rates for several different source and destination transfers are shown in [Table 9-20](#). The following assumptions apply to [Table 9-20](#) and [Table 9-21](#):

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase.
- All slave reads require two wait-states, and slave writes three wait-states, again viewed from the system bus data phase.
- All slave accesses are 32-bits in size.

Table 9-20. eDMA Peak Transfer Rates (MB/Sec)

System Speed, Transfer Size	Internal SRAM-to-Internal SRAM	32-Bit Slave-to-Internal SRAM	Internal SRAM-to-32-Bit Slave (buffering disabled)	Internal SRAM-to-32-Bit Slave (buffering enabled)
66.7 MHz, 32 bit	66.7	66.7	53.3	88.7
66.7 MHz, 64 bit	133.3	66.7	53.3	88.7
66.7 MHz, 256 bit ¹	213.4	N/A ²	N/A ²	N/A ²
83.3 MHz, 32 bit	83.3	83.3	66.7	110.8
83.3 MHz, 64 bit	166.7	83.3	66.7	110.8
83.3 MHz, 256 bit ¹	266.6	N/A ²	N/A ²	N/A ²
100.0 MHz, 32 bit	100.0	100.0	80.0	133.0
100.0 MHz, 64 bit	200.0	100.0	80.0	133.0
100.0 MHz, 256 bit ¹	320.0	N/A ²	N/A ²	N/A ²
132.0 MHz, 32 bit	132.0	132.0	105.6	175.6
132.0 MHz, 64 bit	264.0	132.0	105.6	175.6
132.0 MHz, 256 bit ¹	422.4	N/A ²	N/A ²	N/A ²

¹ A 256-bit transfer occurs as a burst of four 64-bit beats.

² Not applicable: burst access to a slave port is not supported.

Table 9-20 presents a peak transfer rate comparison, measured in MBs per second where the internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width; that is, either 32- or 64-bits per access. For all transfers involving the slave bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, it is assumed the peripheral request causes the channel to move a single slave-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel. The eDMA design supports the following hardware service request sequence:

- Cycle 1: eDMA peripheral request is asserted.
- Cycle 2: The eDMA peripheral request is registered locally in the eDMA module and qualified. (TCD.START bit initiated requests start at this point with the registering of the slave write to TCD bit 255).
- Cycle 3: Channel arbitration begins.
- Cycle 4: Channel arbitration completes. The transfer control descriptor local memory read is initiated.
- Cycle 5–6: The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles.

- Cycle 7: The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus can insert an additional cycle of delay here.
- Cycle 8 – n : The last part of the TCD is read in. This cycle represents the 1st data phase for the read, and the address phase for the destination write.

The exact timing from this point is a function of the response times for the channel's read and write accesses. In this case of an slave read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and slave write, it is 5 cycles.

- Cycle $n + 1$: This cycle represents the data phase of the last destination write.
- Cycle $n + 2$: The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD n fields into the local memory. The control/status fields at word offset 0x1C in TCD n are read. If the major loop is complete, the MAJOR.E_LINK and E_SG bits are checked and processed if enabled.
- Cycle $n + 3$: The appropriate fields in the first part of the TCD n are written back into the local memory.
- Cycle $n + 4$: The fields in the second part of the TCD n are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
- Cycle $n + 5$: The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with slave-to-SRAM (4 cycles) and SRAM-to-slave (5 cycles), DMA requests can be processed every 11.5 cycles ($4 + (4+5)/2 + 3$). This is the time from Cycle 4 to Cycle " $n + 5$." The resulting peak request rate, as a function of the system frequency, is shown in Table 9-21. This metric represents millions of requests per second.

Table 9-21. eDMA Peak Request Rate (MReq/Sec)

System Frequency (MHz)	Request Rate (Zero Wait States)	Request Rate (with Wait States)
66.6	7.4	5.8
83.3	9.2	7.2
100.0	11.1	8.7
133.3	14.8	11.6
150.0	16.6	13.0

A general formula to compute the peak request rate (with overlapping requests) is:

$$PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit]$$

where:

PEAKreq - peak request rate

freq - system frequency

entry - channel startup (four cycles)
 read_ws - wait states seen during the system bus read data phase
 write_ws - wait states seen during the system bus write data phase
 exit - channel shutdown (three cycles)

For example: consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase.
- All slave reads require two wait-states, and slave writes three wait-states, again viewed from the system bus data phase.
- System operates at 150 MHz.

For an SRAM to slave transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [4 + (1 + 1) + (1 + 3) + 3] \text{ cycles} = 11.5 \text{ Mreq/sec}$$

For an slave to SRAM transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [4 + (1 + 2) + (1 + 1) + 3] \text{ cycles} = 12.5 \text{ Mreq/sec}$$

Assuming an even distribution of the two transfer types, the average peak request rate is:

$$\text{PEAKreq} = (11.5 \text{ Mreq/sec} + 12.5 \text{ Mreq/sec}) / 2 = 12.0 \text{ Mreq/sec}$$

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start (no channel is executing, eDMA is idle) are the following:

- 11 cycles for a software (TCD.START bit) request
- 12 cycles for a hardware (eDMA peripheral request signal) request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlap the previous executing channel.

NOTE

When channel linking or scatter/gather is enabled, a two-cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

9.4 Initialization / Application Information

9.4.1 eDMA Initialization

A typical initialization of the eDMA has the following sequence:

1. Write the EDMA_CR if a configuration other than the default is desired.
2. Write the channel priority levels into the EDMA_CPR n registers if a configuration other than the default is desired.
3. Enable error interrupts in the EDMA_EEIRL and/or EDMA_EEIRH registers (optional).

4. Write the 32-byte TCD for each channel that can request service.
5. Enable any hardware service requests via the EDMA_ERQRH and/or EDMA_ERQRL registers.
6. Request channel service by either software (setting the TCD.START bit) or by hardware (slave device asserting its eDMA peripheral request signal).

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the primary transfer control parameter shown in [Table 9-22](#), for the selected channel into its internal address path module. As the TCD is being read, the first transfer is initiated on the system bus unless a configuration error is detected. Transfers from the source (as defined by the source address, TCD.SADDR) to the destination (as defined by the destination address, TCD.DADDR) continue until the specified number of bytes (TCD.NBYTES) have been transferred. When the transfer is complete, the eDMA engine's local TCD.SADDR, TCD.DADDR, and TCD.CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing is executed: for example, interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 9-22. TCD Primary Control and Status Fields

TCD Field Name	Description
START	Control bit to explicitly start channel when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (Cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware-initiated DMA service
BWC	Control bits for "throttling" bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

[Figure 9-22](#) shows how each DMA request initiates one minor loop transfer (iteration) without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (biter).

Example Memory Array			Current Major Loop Iteration Count (CITER)	
DMA Request		Minor Loop	Major Loop	3
	⋮			
DMA Request		Minor Loop		2
	⋮			
DMA Request		Minor Loop	1	
	⋮			

Figure 9-22. Example of Multiple Loop Iterations

Figure 9-23 lists the memory array terms and how the TCD settings interrelate.

xADDR: (Starting Address)	xSIZE: (Size of one data transfer)	Minor Loop (NBYTES in Minor Loop, often the same value as xSIZE)	Offset (xOFF): Number of bytes added to current address after each transfer (Often the same value as xSIZE)
⋮	⋮	Minor Loop	Each DMA Source (S) and Destination (D) has its own: <ul style="list-style-type: none"> • Address (xADDR) • Size (xSIZE) • Offset (xOFF) • Modulo (xMOD) • Last Address Adjustment (xLAST) where x = S or D
xLAST: Number of bytes added to current address after Major Loop (Typically used to loop back)	⋮	Last Minor Loop	Peripheral queues typically have size and offset equal to NBYTES

Figure 9-23. Memory Array Terms

9.4.2 DMA Programming Errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of two errors: group priority error and channel priority error, or EDMA_ESR[GPE] and EDMA_ESR[CPE], respectively.

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the EDMA_ESR. If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group after that group has been selected as the active group. For the example that follows, all of the channel priorities in Group 1 are unique, but some of the channel priorities in Group 0 are the same:

1. Configure the eDMA for fixed-group and fixed-channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and two channels have the same priority level.
4. If Group 1 has service requests pending, those requests are executed.
5. After all Group 1 requests have completed, Group 0 becomes the active group.
6. If Group 0 has a service request, the eDMA selects the undefined channel in Group 0 and generates a channel priority error.
7. Repeat Step 6 until the all Group 0 requests are serviced or a higher-priority Group 1 request is received.

In step 2, the eDMA acknowledge lines assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, an error interrupt is generated. However, the channel number for the EDMA_ER and the error interrupt request line contain undefined data because the channel is ‘undefined’. A group priority error is global and any request in any group causes a group priority error.

If priority levels are not unique, the highest (channel/group) priority that has an active request is selected, but the lowest numbered (channel/group) with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts and error reporting are associated with the selected channel.

9.4.3 DMA Request Assignments

The assignments between the DMA requests from the modules to the channels of the eDMA are shown in [Table 9-23](#). The source column is written in C language syntax. The syntax is `module_instance.register[bit]`.

Table 9-23. DMA Request Summary for eDMA

DMA Request	Channel	Source	Description
eQADC_FISR0_CFFF0	0	EQADC.FISR0[CFFF0]	eQADC Command FIFO 0 Fill Flag
eQADC_FISR0_RFDF0	1	EQADC.FISR0[RFDF0]	eQADC Receive FIFO 0 Drain Flag
eQADC_FISR1_CFFF1	2	EQADC.FISR1[CFFF1]	eQADC Command FIFO 1 Fill Flag
eQADC_FISR1_RFDF1	3	EQADC.FISR1[RFDF1]	eQADC Receive FIFO 1 Drain Flag
eQADC_FISR2_CFFF2	4	EQADC.FISR2[CFFF2]	eQADC Command FIFO 2 Fill Flag
eQADC_FISR2_RFDF2	5	EQADC.FISR2[RFDF2]	eQADC Receive FIFO 2 Drain Flag
eQADC_FISR3_CFFF3	6	EQADC.FISR3[CFFF3]	eQADC Command FIFO 3 Fill Flag
eQADC_FISR3_RFDF3	7	EQADC.FISR3[RFDF3]	eQADC Receive FIFO 3 Drain Flag
eQADC_FISR4_CFFF4	8	EQADC.FISR4[CFFF4]	eQADC Command FIFO 4 Fill Flag

Table 9-23. DMA Request Summary for eDMA (continued)

DMA Request	Channel	Source	Description
eQADC_FISR4_RFDF4	9	EQADC.FISR4[RFDF4]	eQADC Receive FIFO 4 Drain Flag
eQADC_FISR5_CFFF5	10	EQADC.FISR5[CFFF5]	eQADC Command FIFO 5 Fill Flag
eQADC_FISR5_RFDF5	11	EQADC.FISR5[RFDF5]	eQADC Receive FIFO 5 Drain Flag

eTPU_CDTRSR_A_DTRS15	31	ETPU.CDTRSR_A[DTRS15]	eTPUA Channel 15 Data Transfer Request Status

9.4.4 DMA Arbitration Mode Considerations

9.4.4.1 Fixed-Group Arbitration and Fixed-Channel Arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so the channels within one group use ‘fixed’ priorities, and that group is assigned the highest ‘fixed’ priority of all groups, it is possible for that group to take all the bandwidth of the eDMA controller; that is, no other groups is serviced if there is always at least one

DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

9.4.4.2 Round-Robin Group Arbitration, Fixed-Channel Arbitration

The occurrence of one or more DMA requests from one or more groups, the channel with the highest priority from a specific group is serviced first. Groups are serviced starting with the highest group number with a service request and rotating through to the lowest group number containing a service request.

After the channel request is serviced, the group round-robin algorithm selects the highest pending request from the next group in the round-robin sequence. Servicing continues using the round-robin method, always servicing the highest priority channel in the next group in the sequence, or just skipping a group if it has no pending requests.

If a channel requests service at a rate that equals or exceeds the round-robin service rate, then that channel is always serviced before lower priority channels in the same group, and thus the lower priority channels never are serviced. The advantage of this scenario is that no one group uses all the eDMA bandwidth. The highest priority channel selection latency is potentially greater than fixed/fixed arbitration. Excessive request rates on high priority channels can prevent the servicing of lower priority channels in the same group.

9.4.4.3 Round-Robin Group Arbitration, Round-Robin Channel Arbitration

Groups are serviced as described in [Section 9.4.4.2, “Round-Robin Group Arbitration, Fixed-Channel Arbitration](#), but this time channels are serviced in channel number order. Only one channel is serviced from each requesting group for each round-robin pass through the groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to channel priority levels.

Because channels are serviced using a round-robin method, any channel that generates DMA requests faster than a combination of the group round-robin service rate and the channel service rate for its group does not prevent the servicing of other channels in its group. Any DMA requests that are not serviced are simply lost, but at least one channel is serviced.

This scenario ensures that all channels are guaranteed service at some point, regardless of the request rates. However, the potential latency can be quite high. All channels are treated equally. Priority levels are not used in round-robin/round-robin mode.

9.4.4.4 Fixed-Group Arbitration, Round-Robin Channel Arbitration

The highest priority group with a request is serviced. Lower priority groups are serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This can cause the same bandwidth problem indicated in Section 9.4.4.1, but all the channels in the highest priority group are serviced. Service latency is short on the highest-priority group, but increases as the group priority decreases.

9.4.5 DMA Transfer

9.4.5.1 Single Request

To perform a simple transfer of ‘*n*’ bytes of data with one activation, set the major loop to 1 (TCD.CITER = TCD.BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer completes, the TCD.DONE bit is set and an interrupt is generated if correctly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a word-wide port located at 0x2000. The address offsets are programmed in increments to match the size of the transfer; one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCD.CITER = TCD.BITER = 1
TCD.NBYTES = 16
TCD.SADDR = 0x1000
TCD.SOFF = 1
TCD.SSIZE = 0
TCD.SLAST = -16
TCD.DADDR = 0x2000
TCD.DOFF = 4
TCD.DSIZE = 2
TCD.DLAST_SGA = -16
TCD.INT_MAJ = 1
TCD.START = 1 (Initialize all other fields before writing to this bit)
All other TCD fields = 0
```

This generates the following sequence of events:

1. Slave write to the TCD.START bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD.DONE = 0, TCD.START = 0, TCD.ACTIVE = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
 - a) read_byte (0x1000), read_byte(0x1001), read_byte(0x1002), read_byte(0x1003)
 - b) write_word (0x2000) -> first iteration of the minor loop

- c) read_byte (0x1004), read_byte(0x1005), read_byte(0x1006), read_byte(0x1007)
 - d) write_word (0x2004) -> second iteration of the minor loop
 - e) read_byte (0x1008), read_byte(0x1009), read_byte(0x100a), read_byte(0x100b)
 - f) write_word (0x2008) -> third iteration of the minor loop
 - g) read_byte (0x100c), read_byte(0x100d), read_byte(0x100e), read_byte(0x100f)
 - h) write_word (0x200c) -> last iteration of the minor loop -> major loop complete
6. eDMA engine writes: TCD.SADDR = 0x1000, TCD.DADDR = 0x2000, TCD.CITER = 1 (TCD.BITER).
 7. eDMA engine writes: TCD.ACTIVE = 0, TCD.DONE = 1, EDMA_IRQR_n = 1.
 8. The channel retires.

The eDMA goes idle or services the next channel.

9.4.5.2 Multiple Requests

The next example is the same as previous with the exception of transferring 32 bytes via two hardware requests. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the EDMA_ERQR, channel service requests are initiated by the slave device (set ERQR after TCD; TCD.START = 0).

```

TCD.CITER = TCD.BITER = 2
TCD.NBYTES = 16
TCD.SADDR = 0x1000
TCD.SOFF = 1
TCD.SSIZE = 0
TCD.SLAST = -32
TCD.DADDR = 0x2000
TCD.DOFF = 4
TCD.DSIZE = 2
TCD.DLAST_SGA = -32
TCD.INT_MAJ = 1
TCD.START = 0 (Initialize all other fields before writing this bit.)
All other TCD fields = 0
    
```

This generates the following sequence of events:

1. First hardware (eDMA peripheral request) request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD.DONE = 0, TCD.START = 0, TCD.ACTIVE = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.

5. The source to destination transfers execute as follows:
 - a) read_byte (0x1000), read_byte (0x1001), read_byte (0x1002), read_byte (0x1003)
 - b) write_word (0x2000) -> first iteration of the minor loop
 - c) read_byte (0x1004), read_byte (0x1005), read_byte (0x1006), read_byte (0x1007)
 - d) write_word (0x2004) -> second iteration of the minor loop
 - e) read_byte (0x1008), read_byte (0x1009), read_byte (0x100a), read_byte (0x100b)
 - f) write_word (0x2008) -> third iteration of the minor loop
 - g) read_byte (0x100c), read_byte (0x100d), read_byte (0x100e), read_byte (0x100f)
 - h) write_word (0x200c) -> last iteration of the minor loop
6. eDMA engine writes: TCD.SADDR = 0x1010, TCD.DADDR = 0x2010, TCD.CITER = 1.
7. eDMA engine writes: TCD.ACTIVE = 0.
8. The channel retires -> one iteration of the major loop.

The eDMA goes idle or services the next channel.

9. Second hardware (eDMA peripheral request) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD.DONE = 0, TCD.START = 0, TCD.ACTIVE = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers execute as follows:
 - a) read_byte (0x1010), read_byte (0x1011), read_byte (0x1012), read_byte (0x1013)
 - b) write_word (0x2010) -> first iteration of the minor loop
 - c) read_byte (0x1014), read_byte (0x1015), read_byte (0x1016), read_byte (0x1017)
 - d) write_word (0x2014) -> second iteration of the minor loop
 - e) read_byte (0x1018), read_byte (0x1019), read_byte (0x101a), read_byte (0x101b)
 - f) write_word (0x2018) -> third iteration of the minor loop
 - g) read_byte (0x101c), read_byte (0x101d), read_byte (0x101e), read_byte (0x101f)
 - h) write_word (0x201c) -> last iteration of the minor loop -> major loop complete
14. eDMA engine writes: TCD.SADDR = 0x1000, TCD.DADDR = 0x2000, TCD.CITER = 2 (TCD.BITER).
15. eDMA engine writes: TCD.ACTIVE = 0, TCD.DONE = 1, EDMA_IRQR_n = 1.
16. The channel retires -> major loop complete.

The eDMA goes idle or services the next channel.

9.4.5.3 Modulo Feature

The modulo feature of the eDMA provides the ability to easily implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and specifies which lower address bits are incremented from their original value after the address + offset calculation. All upper address bits remain the same as in the original value. Clearing this field to 0 disables the modulo feature.

Table 9-24 shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the mod field is set to 4, allowing for a 2⁴ byte (16-byte) size queue.

Table 9-24. Modulo Feature Example

Transfer Number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

9.4.6 TCD Status

9.4.6.1 Minor Loop Complete

There are two methods to test for minor loop completion when using software initiated service requests. The first method is to read the TCD.CITER field and test for a change. Another method can be extracted from the following sequence. The second method is to test the TCD.START bit AND the TCD.ACTIVE bit. The minor loop complete condition is indicated by both bits reading zero after the TCD.START was written to a one. Polling the TCD.ACTIVE bit can be inconclusive because the active status can be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

1. TCD.START = 1, TCD.ACTIVE = 0, TCD.DONE = 0 (issued service request via software)
2. TCD.START = 0, TCD.ACTIVE = 1, TCD.DONE = 0 (executing)
3. TCD.START = 0, TCD.ACTIVE = 0, TCD.DONE = 0 (completed minor loop and is idle) or
4. TCD.START = 0, TCD.ACTIVE = 0, TCD.DONE = 1 (completed major loop and is idle)

The best method to test for minor loop completion when using hardware initiated service requests is to read the TCD.CITER field and test for a change. The hardware request and acknowledge handshakes signals are not visible in the programmer’s model.

The TCD status bits execute the following sequence for a hardware activated channel:

1. eDMA peripheral request asserts (issued service request via hardware)
2. TCD.START = 0, TCD.ACTIVE = 1, TCD.DONE = 0 (executing)
3. TCD.START = 0, TCD.ACTIVE = 0, TCD.DONE = 0 (completed minor loop and is idle) or
4. TCD.START = 0, TCD.ACTIVE = 0, TCD.DONE = 1 (completed major loop and is idle)

For both activation types, the major loop complete status is explicitly indicated via the TCD.DONE bit.

The TCD.START bit is cleared automatically when the channel begins execution regardless of how the channel was activated.

9.4.6.2 Active Channel TCD Reads

The eDMA reads the true TCD.SADDR, TCD.DADDR, and TCD.NBYTES values if read while a channel is executing. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine is currently using in its internal register file and not the values in the TCD local memory for that channel. The addresses (SADDR and DADDR) and NBYTES (decrements to zero as the transfer progresses) can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

9.4.6.3 Preemption Status

Preemption is only available when fixed arbitration is selected for both group and channel arbitration modes. A preempt-able situation is one in which a preempt-enabled channel is running and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the relative priority of the actively running and the outstanding requests become undefined. Channel and/or group priorities are treated as equal (or more exactly, constantly rotating) when round-robin arbitration mode is selected.

The TCD.ACTIVE bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one iteration of the major loop. Two TCD.ACTIVE bits set at the same time in the overall TCD map indicates a higher priority channel is actively preempting a lower priority channel.

9.4.7 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD.START bit of another channel (or itself) thus initiating a service request for that channel. This operation is automatically performed by the eDMA engine at the conclusion of the major or minor loop when properly enabled.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD.CITER.E_LINK field are used to determine whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the minor loop except for the last.

When the major loop is exhausted, only the major loop channel link fields are used to determine whether to make a channel link. For example, with the initial fields of:

```
TCD.CITER.E_LINK = 1
TCD.CITER.LINKCH = 0xC
TCD.CITER value = 0x4
TCD.MAJOR.E_LINK = 1
TCD.MAJOR.LINKCH = 0x7
```

channel linking executes as:

1. Minor loop done -> set channel 12 TCD.START bit
2. Minor loop done -> set channel 12 TCD.START bit
3. Minor loop done -> set channel 12 TCD.START bit
4. Minor loop done, major loop done -> set channel 7 TCD.START bit

When minor loop linking is enabled (TCD.CITER.E_LINK = 1), the TCD.CITER field uses a nine bit vector to form the current iteration count.

When minor loop linking is disabled (TCD.CITER.E_LINK = 0), the TCD.CITER field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD.CITER.LINKCH field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

After configuration, the TCD.CITER.E_LINK bit and the TCD.BITER.E_LINK bit must be equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

Table 9-25 summarizes how a DMA channel can “link” to another DMA channel, i.e, use another channel’s TCD, at the end of a loop.

Table 9-25. Channel Linking Parameters

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	citer.e_link	Enable channel-to-channel linking on minor loop completion (current iteration)
	citer.linkch	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	major.e_link	Enable channel-to-channel linking on major loop completion
	major.linkch	Link channel number when linking at end of major loop

9.4.8 Dynamic Programming

This section provides recommended methods to change the programming model during channel execution.

9.4.8.1 Dynamic Channel Linking and Dynamic Scatter/Gather

Dynamic channel linking and dynamic scatter/gather is the process of changing the TCD.MAJOR.E_LINK or TCD.E_SG bits during channel execution. These bits are read from the TCD local memory at the *end* of channel execution thus allowing the user to enable either feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.MAJOR.E_LINK bit at the same time the eDMA engine is retiring the channel. The TCD.MAJOR.E_LINK is set in the programmer's model, but it is unclear whether the link completed before the channel retired.

Use the following coherency model when executing a dynamic channel link or dynamic scatter/gather request:

1. Set the TCD.MAJOR.E_LINK bit
2. Read the TCD.MAJOR.E_LINK bit
3. Test the TCD.MAJOR.E_LINK request status:
 - a) If the bit is set, the dynamic link attempt was successful.
 - b) If the bit is cleared, the channel had already retired before the dynamic link completed.

This same coherency model is true for dynamic scatter/gather operations. For both dynamic requests, the TCD local memory controller forces the TCD.MAJOR.E_LINK and TCD.E_SG bits to zero on any writes to a channel's TCD after that channel's TCD.DONE bit is set indicating the major loop is complete.

NOTE

The user must clear the TCD.DONE bit before writing the TCD.MAJOR.E_LINK or TCD.E_SG bits. The TCD.DONE bit is cleared automatically by the eDMA engine after a channel begins execution.

9.5 Document Revision History

Table 9-26. Changes Between MPC5565RM Revisions 0.1 and 1

Description of Change
<p>In the section on DMA Performance, made this change:</p> <ul style="list-style-type: none"> • From: removed eDMA Peak Transfer Rate table • To: Added an eDMA Peak Transfer Rates table (Table 9-20) with columns that show the effect of buffering enabled and disabled.
<p>To the TCD Structure diagram, added this footnote to the CITER and BITER fields: “If channel linking on minor link completion is disabled, TCD bits [161:175] are used to form a 15-bit CITER field; if channel-to-channel linking is enabled, CITER becomes a 9-bit field.”</p>
<p>The following phrase added to the BWC bit: “To minimize start-up latency, bandwidth control stalls are suppressed for the first two system bus cycles and after the last write of each minor loop.”</p>
<p>Added the following phrase to the BWC bit: “To minimize start-up latency, bandwidth control stalls are suppressed for the first two system bus cycles and after the last write of each minor loop.”</p>
<p>Corrected address of footnote 2 in Figure 9-18.</p>

Chapter 10

Interrupt Controller (INTC)

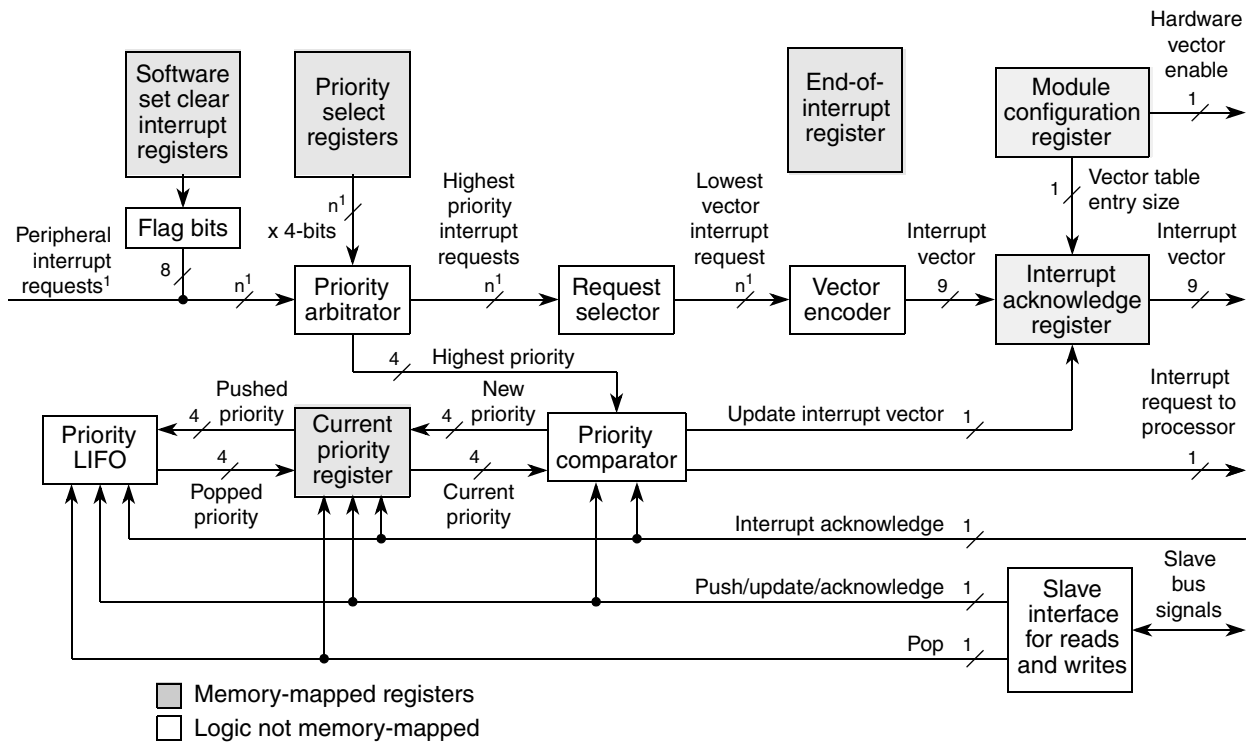

10.1 Introduction

This chapter describes the interrupt controller (INTC), which schedules interrupt requests (IRQs) from software and internal peripherals to the e200z6 core. The INTC provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support.

Interrupts implemented by the MCU are defined in the *e200z6 PowerPC™ Core Reference Manual*.

10.1.1 Block Diagram

Figure 4-1 shows details of the interrupt controller.

¹ Although N (maximum number of addressable IRQ vectors) = 231, the total number of interrupts must be a multiple of four. Therefore, the total number of interrupts is 232: 208 peripheral IRQs, 8 software-configurable IRQs, and 16 reserved.

Figure 10-1. INTC Block Diagram

10.1.2 Overview

Interrupt functionality for the device is handled between the e200z6 core and the interrupt controller. The CPU core has 19 exception sources, each of which can interrupt the core. One exception source is from the interrupt controller (INTC). The INTC provides priority-based preemptive scheduling of interrupt requests. This scheduling scheme is suitable for statically scheduled hard real-time systems. The INTC is optimized for a large number of interrupt requests. It is targeted to work with a PowerPC book E processor and automotive powertrain applications where the ISRs nest to multiple levels.

Table 10-1 displays the interrupt sources and the number of interrupts available for each module; Figure 10-2 shows a general diagram of INTC software vector mode.

Table 10-1. Interrupt Sources Available

Interrupt Source (IRQs)	Number of Interrupts Available
Software	8
Watchdog	1
Memory	1
eDMA	33
FMPLL	2
External IRQ input pins	6
eMIOS	24
eTPU engine A	33
eQADC	31
DSPi	15
eSCI	2
FlexCAN	60

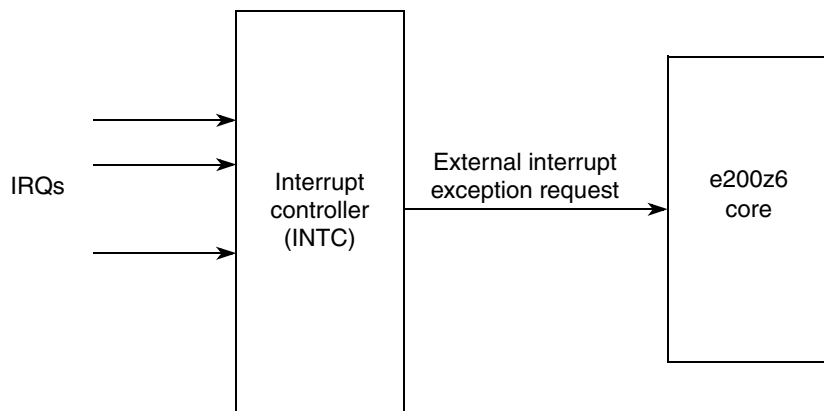

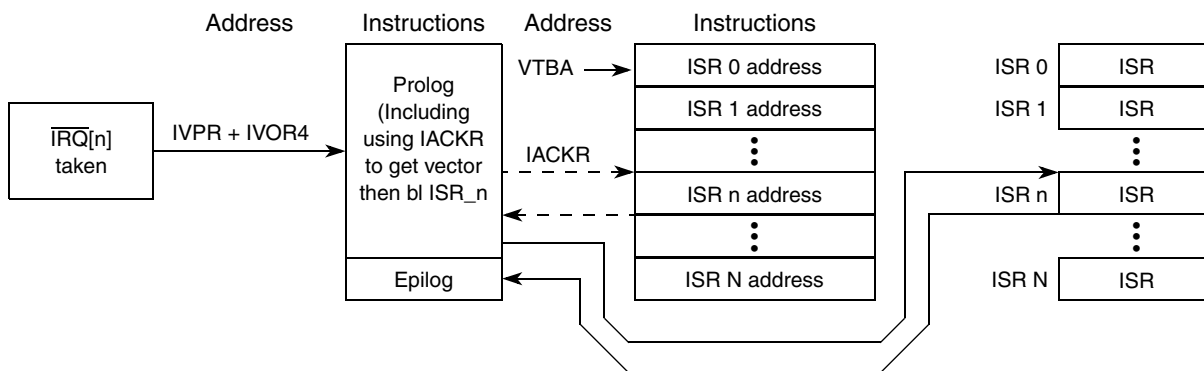

Figure 10-2. INTC Software Vector Mode

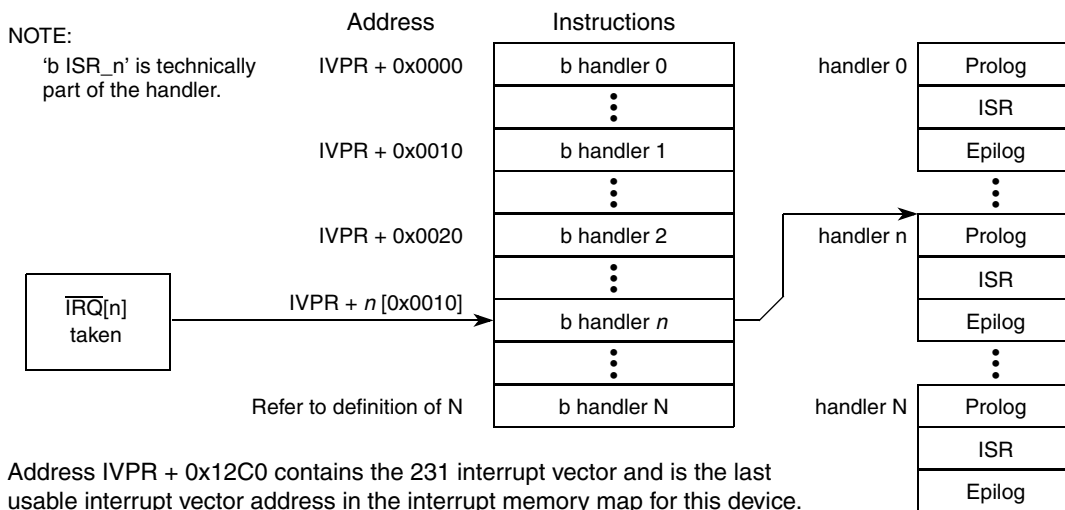

Two modes are available to determine the vector for the interrupt request source: software vector mode and hardware vector mode. In software vector mode, as shown in Figure 10-2, the e200z6 branches to a common interrupt exception handler whose location is determined by an address derived from special purpose registers IVPR and IVOR4. The interrupt exception handler reads the INTC_IACKR to determine the vector of the interrupt request source. Typical program flow for software vector mode is shown in Figure 10-3.

N is the maximum number of usable interrupt vectors, which equals 231, and includes 16 reserved IRQ vectors and eight software-settable IRQ vectors. Because the memory is mapped in four-byte words, the total number of interrupt vectors must be a multiple of four, therefore one more interrupt vector exists to complete the word. This results in a total of 232 interrupt vectors. However, interrupt vector 232 is reserved and not available.

Figure 10-3. Program Flow—Software Vector Mode

In hardware vector mode, the core branches to an interrupt exception handler unique for each interrupt request source. Typical program flow for hardware vector mode is shown in Figure 10-4.

Address IVPR + 0x12C0 contains the 231 interrupt vector and is the last usable interrupt vector address in the interrupt memory map for this device.

N is the maximum number of usable interrupt vectors, which equals 231 (address is IVPR + 0x12C0), and includes 16 reserved IRQ vectors and eight software-settable IRQ vectors. Because the memory is mapped in four-byte words, the total number of interrupt registers must be a multiple of four, therefore another interrupt vector exists in memory to complete the word for a total of 232 interrupt vectors. However, the 232 interrupt vector is reserved and is not available.

Figure 10-4. Program Flow—Hardware Vector Mode

For high priority interrupt requests in these target applications, the time from the assertion of the interrupt request from the peripheral to when the processor is performing useful work to service the interrupt request needs to be minimized. The INTC can be optimized to support this goal through the hardware vector mode, where a unique vector is provided for each interrupt request source. It also provides 16 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application has different priorities for each source of interrupt request, the priority of each interrupt request is configurable.

When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the priority ceiling protocol for coherent accesses. By providing a modifiable priority mask, the priority level can be raised temporarily so that no task can preempt another task that shares the same resource.

Multiple processors can assert interrupt requests to each other through software settable interrupt requests, i.e., by using application software to assert an interrupt request. These same software settable interrupt requests also can be used to break the work involved in servicing an interrupt request into a high priority portion and a low priority portion. The high priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software settable interrupt request to finish the servicing in a lower priority ISR.

10.1.3 Features

Features include the following:

- Total number of interrupt vectors is 232¹, of which
 - 8 are software settable sources, and
 - 16 are reserved sources.
- 9-bit unique vector for each interrupt request source in hardware vector mode.
- Each interrupt source can be programmed to one of 16 priorities.
- Preemption.
 - Preemptive prioritized interrupt requests to processor.
 - ISR at a higher priority preempts ISRs or tasks at lower priorities.
 - Automatic pushing or popping of preempted priority to or from a LIFO.
 - Ability to modify the ISR or task priority. Modifying the priority can be used to implement the priority ceiling protocol for accessing shared resources.
- Low latency—three clocks from receipt of interrupt request from peripheral to interrupt request to processor.

10.1.4 Modes of Operation

The interrupt controller has two handshaking modes with the processor: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_MCR[HVEN], determines which mode is used.

1. Although N (maximum number of addressable IRQ vectors) = 231, the total number of interrupts must be a multiple of four. Therefore, the total number of interrupts is 232: 208 peripheral IRQs, 8 software-configurable IRQs, and 16 reserved.

In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

10.1.4.1 Software Vector Mode

In software vector mode, there is a common interrupt exception handler address which is calculated by hardware as shown in [Figure 10-5](#). The upper half of the interrupt vector prefix register (IVPR) is added to the offset contained in the external input interrupt vector offset register (IVOR4). Note that since bits IVOR4[28:31] are not part of the offset value, the vector offset must be located on a quad-word (16-byte) aligned location in memory.

In software vector mode, the interrupt exception handler software must read the INTC interrupt acknowledge register (INTC_IACKR) to obtain the vector associated with the corresponding peripheral or software interrupt request. The INTC_IACKR register contains a 32-bit address for a vector table base address (VTBA) plus an offset to access the interrupt vector (INTVEC). The address is then used to branch to the corresponding routine for that peripheral or software interrupt source.

Figure 10-5. Software Vector Mode: Interrupt Exception Handler Address Calculation

Reading the INTC_IACKR acknowledges the INTC's interrupt request and negates the interrupt request to the processor. The interrupt request to the processor does not clear if a higher priority interrupt request arrives. Even in this case, INTVEC does not update to the higher priority request until the lower priority interrupt request is acknowledged by reading the INTC_IACKR. The reading also pushes the PRI value in the INTC current priority register (INTC_CPR) onto the LIFO and updates PRI in the INTC_CPR with the priority of the interrupt request. The INTC_CPR masks any peripheral or software settable interrupt request at the same or lower priority of the current value of the PRI field in INTC_CPR from generating an interrupt request to the processor.

The interrupt exception handler must write to the end-of-interrupt register (INTC_EOIR) to complete the operation. Writing to the INTC_EOIR ends the servicing of the interrupt request. The INTC's LIFO is popped into the INTC_CPR's PRI field by writing to the INTC_EOIR, and the size of a write does not affect the operation of the write. Those values and sizes written to this register neither update the INTC_EOIR contents nor affect whether the LIFO pops. For possible future compatibility, write four bytes of all 0s to the INTC_EOIR. The timing relationship between popping the LIFO and disabling recognition of external input has no restriction. The writes can happen in either order.

However, disabling recognition of the external input before popping the LIFO eases the calculation of the maximum stack depth at the cost of postponing the servicing of the next interrupt request.

10.1.4.2 Hardware Vector Mode

In hardware vector mode, the interrupt exception handler address is specific to the peripheral or software settable interrupt source rather than being common to all of them. No IVOR is used. The interrupt exception handler address is calculated by hardware as shown in Figure 10-6. The upper half of the interrupt vector prefix register (IVPR) is added to an offset which corresponds to the peripheral or software interrupt source which caused the interrupt request. The offset matches the value in the Interrupt Vector field, INTC_IACKR[INTVEC]. Each interrupt exception handler address is aligned on a quad word (16-byte) boundary. IVOR4 is not used in this mode, and software does not need to read INTC_IACKR to get the interrupt vector number.

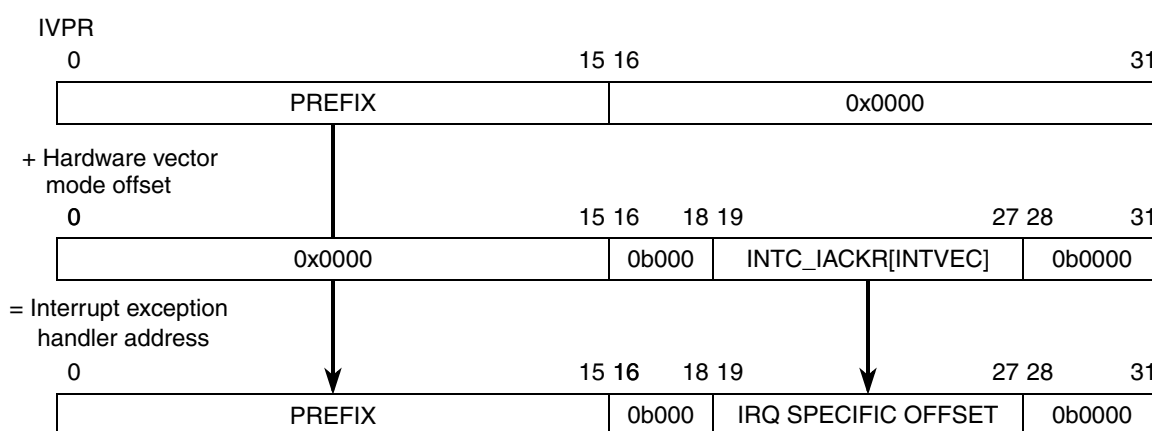

Figure 10-6. Hardware Vector Mode: Interrupt Exception Handler Address Calculation

The processor negates INTC's interrupt request when automatically acknowledging the interrupt request. However, the interrupt request to the processor do not negate if a higher priority interrupt request arrives. Even in this case, the interrupt vector number does not update to the higher priority request until the lower priority request is acknowledged by the processor.

The assertion of the interrupt acknowledge signal pushes the PRI value in the INTC_CPR onto the LIFO and updates PRI in the INTC_CPR with the new priority.

10.2 External Signal Description

The INTC does not have any direct external MCU signals. However, there are fifteen external pins which can be configured in the SIU as external interrupt request input pins. When configured in this function, an interrupt on the pin sets an external interrupt flag. These flags can cause one of five peripheral interrupt requests to the interrupt controller.

For more information on external interrupts, the pins used, and how to configure them:

Refer to [Table 10-2](#) for a list and number of the external interrupt pins.

Refer to the SIU chapter for more information on these pins.

Table 10-2. External Interrupt Signals

Function ¹	P/A/G ²	Description	I/O Type	Reset Function/ State ³	Post Reset Function/ State ⁴

¹ When the HVEN bit in the INTC_MCR is asserted, a read of the INTC_IACKR has no side effects.

² The PRI fields are “Reserved” for peripheral interrupt requests whose vectors are labeled as Reserved in Table 10-9.

10.3.1 Register Descriptions

With the exception of the INTC_SSCIn and INTC_PSR n registers, all of the registers are 32-bits wide. Any combination of accessing the 4-bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, and aligned 32 bits.

Although INTC_SSCIn and INTC_PSR n are 8 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

In software vector mode, the side effects of a read of the INTC interrupt acknowledge register (INTC_IACKR) are the same regardless of the size of the read. In either software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR) does not affect the operation of the write.

10.3.1.1 INTC Module Configuration Register (INTC_MCR)

The INTC_MCR is used to configure options of the INTC.

Address: Base + 0x0000 (INTC_MCR)

Figure 10-7. INTC Module Configuration Register (INTC_MCR)

Table 10-4. INTC_MCR Field Descriptions

Field	Description
0–25	Reserved, must be cleared.
26 VTES	Vector table entry size. Controls the number of '0's to the right of INTVEC in Section 10.3.1.3, "INTC Interrupt Acknowledge Register (INTC_IACKR) . If the contents of INTC_IACKR are used as an address of an entry in a vector table as in software vector mode, then the number of rightmost '0's determines the size of each vector table entry. VTES impacts software vector mode operation but also affects the INTC_IACKR[INTVEC] position in both hardware vector mode and software vector mode. 0 4 bytes (Normal expected use) 1 8 bytes
27–30	Reserved, must be cleared.
31 HVEN	Hardware vector enable. Controls whether the INTC is in hardware vector mode or software vector mode. Refer to Section 10.1.4, "Modes of Operation" , for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode

10.3.1.2 INTC Current Priority Register (INTC_CPR)

The INTC_CPR masks any peripheral or software settable interrupt request set at the same or lower priority as the current value of the INTC_CPR[PRI] field from generating an interrupt request to the processor. When the INTC interrupt acknowledge register (INTC_IACKR) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR) is written, the LIFO is popped into the INTC_CPR's PRI field.

The masking priority can be raised or lowered by writing to the PRI field, supporting the PCP. Refer to [Section 10.5.5, "Priority Ceiling Protocol."](#)

NOTE

On some Power Architecture MCUs, a store to raise the PRI field which closely precedes an access to a shared resource can result in a non-coherent access to that resource unless an **mbar** or **msync** followed by an **isync** sequence of instructions is executed between the accesses. An **mbar** or **msync** instruction is also necessary after accessing the resource but before lowering the PRI field. Refer to [Section 10.5.5.2, "Ensuring Coherency."](#)

Figure 10-8. INTC Current Priority Register (INTC_CPR)

Table 10-5. INTC_CPR Field Descriptions

Field	Description
0–27	Reserved, must be cleared.
28–31 PRI	Priority. PRI is the priority of the currently executing ISR according to the field values defined below. 1111 Priority 15 (highest) 1110 Priority 14 ... 0001 Priority 1 0000 Priority 0 (lowest)

10.3.1.3 INTC Interrupt Acknowledge Register (INTC_IACKR)

The INTC_IACKR provides a value that can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

In software vector mode, reading the INTC_IACKR acknowledges the INTC's interrupt request. Refer to [Section 10.1.4.1, “Software Vector Mode”](#) for a detailed description of the effect on the interrupt request to the processor. The reading also pushes the PRI value in the INTC current priority register (INTC_CPR) onto the LIFO and updates PRI in the INTC_CPR with the priority of the interrupt request. The side effect from the reads in software vector mode, that is, the effect on the interrupt request to the processor, the current priority, and the LIFO, are the same regardless of the size of the read

Reading the INTC_IACKR does not have side effects in hardware vector mode.

NOTE

The INTC_IACKR must not be read speculatively while in software vector mode. Therefore, for future compatibility, the TLB entry covering the INTC_IACKR must be configured to be guarded.

In software vector mode, the INTC_IACKR must be read before setting MSR[EE]. No synchronization instruction is needed after reading the INTC_IACKR and before setting MSR[EE].

However, the time for the processor to recognize the assertion or negation of the external input to it is not defined by the book E architecture and can be greater than 0. Therefore, insert instructions between the reading of the INTC_IACKR and the setting of MSR[EE] that consumes at least two processor clock cycles. This length of time allows the interrupt request negation to propagate through the processor before MSR[EE] is set.

Figure 10-10. INTC Interrupt Acknowledge Register (INTC_IACKR)—INTC_MCR[VTES] = 1

Table 10-6. INTC_IACKR Field Descriptions

Field	Description
0–20 or 0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs. The VTBA only uses the left-most 20 bits when the VTES bit in INTC_MCR is asserted.
21–29 or 20–28 INTVEC	Interrupt vector. Vector of peripheral or software-settable interrupt requests that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode. Note: If INTC_MCR[VTES] = 1, then the INTVEC field is shifted left one position to bits 20–28. VTBA is then shortened by one bit to bits 0–19.
30–31	Reserved, must be cleared.

10.3.1.4 INTC End-of-Interrupt Register (INTC_EOIR)

Writing to the INTC_EOIR signals the end of the servicing of the interrupt request. When the INTC_EOIR is written, the priority last pushed on the LIFO is popped into INTC_CPR. The values and size of data written to the INTC_EOIR are ignored. Those values and sizes written to this register neither update the INTC_EOIR contents or affect whether the LIFO pops. For possible future compatibility, write four bytes of all 0's to the INTC_EOIR.

Reading the INTC_EOIR has no effect on the LIFO.

Figure 10-11. INTC End-of-Interrupt Register (INTC_EOIR)

10.3.1.5 INTC Software Set/Clear Interrupt Registers (INTC_SSCIR0–7)

The INTC_SSCIR_n support the setting or clearing of software settable interrupt requests. These registers contain eight independent sets of bits to set and clear a corresponding flag bit by software. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET_n leaves SET_n unchanged at 0 but sets CLR_n. Writing a 0 to SET_n has no effect. CLR_n is the flag bit. Writing a 1 to CLR_n clears it. Writing a 0 to CLR_n has no effect. If a 1 is written to a pair SET_n and CLR_n bits at the same time, CLR_n is asserted, regardless of whether CLR_n was asserted before the write.

Although INTC_SSCIR_n is 8 bits wide, it can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Address: Base + 0x0020 + *n* (INTC_SSCIR_n); *n* = 0–7

Access: R/W

	0	1	2	3	4	5	6	7
R	0	0	0	0	0	0	0	CLR _n
W							SET _n	
Reset	0	0	0	0	0	0	0	0

Figure 10-12. INTC Software Set/Clear Interrupt Register (INTC_SSCIR_n)

Table 10-7. INTC_SSCIR_n Field Descriptions

Field	Description
0–5	Reserved, must be cleared.
6 SET _n	Set flag bits. Writing a 1 sets the corresponding CLR _n bit. Writing a 0 has no effect. Each SET _n is always read as a 0.
7 CLR _n	Clear flag bits. CLR _n is the flag bit. Writing a 1 to CLR _n clears it provided that a 1 is not written simultaneously to its corresponding SET _n bit. Writing a 0 to CLR _n has no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

10.3.1.6 INTC Priority Select Registers (INTC_PSR0–231)

The INTC_PSR_n support the selection of an individual priority for each source of interrupt request. The unique vector of each peripheral or software settable interrupt request determines which INTC_PSR_n is assigned to that interrupt request. The software settable interrupt requests 0–7 are assigned vectors 0–7, and their priorities are configured in INTC_PSR0–INTC_PSR7, respectively. The peripheral interrupt requests are assigned vectors 8–231 and their priorities are configured in INTC_PSR8 through INTC_PSR231, respectively.

Although INTC_PSR_n is 8 bits wide, it can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

NOTE

The PRI_n field of an INTC_PSR_n must not be modified while its corresponding peripheral or software settable interrupt request is asserted.

Address: Base + 0x0040 + *n* (INTC_PSR_n); *n* = 0–231

Table 10-8. INTC_SSCIR n Field Descriptions

Field	Description
0–3	Reserved, must be cleared.
4–7 PRI n	Priority select. Selects the priority for corresponding interrupt request. 1111 Priority 15 (highest) 1110 Priority 14 ... 0001 Priority 1 0000 Priority 0 (lowest)

10.4 Functional Description

10.4.1 Interrupt Request Sources

The INTC has two types of interrupt requests, peripheral and software settable. The assignments between the interrupt requests from the modules to the vectors for input to the e200z6 are shown in [Table 10-9](#). The Offset column lists the IRQ specific offsets when using hardware vector mode. The Source column is written in C language syntax. The syntax is ‘module_register[bit].’ Interrupt requests from the same module location or ORed together. The individual interrupt priorities are selected in INTC_PSR n , where the specific select register is assigned according to the vector.

Table 10-9. MPC5565 Interrupt Request Sources

¹ The vector number is used to identify the interrupt and does not indicate the maximum number of usable interrupt sources.

² Interrupt requests from the same module location are ORed together.

NOTE

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software settable interrupt request (whose PRI_n value in INTC_PSR0–INTC_PSR231 is higher than the PRI value in INTC_CPR) negates before the interrupt request to the processor for that peripheral or software settable interrupt request is acknowledged, the interrupt request to the processor still can assert or remain asserted for that peripheral or software settable interrupt request. If the interrupt request to the processor does assert or does remain asserted, the interrupt vector corresponds to that peripheral or software settable interrupt request. Also, the PRI value in the INTC_CPR is updated with the PRI_n value in INTC_PSR n .

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral or, alternatively, setting its mask bit has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

10.4.1.1 Peripheral Interrupt Requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC to the time that the INTC starts to drive the interrupt request to the processor is three clocks.

10.4.1.2 Software Settable Interrupt Requests

The software set/clear interrupt registers (INTC_SSCIR $_x_x$) support the setting or clearing of software-settable interrupt requests. These registers contain eight independent sets of bits to set and clear a corresponding flag bit by software. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request.

An interrupt request is triggered by software writing a 1 to the SET n bit in INTC software set/clear interrupt registers (INTC_SSCIR0–INTC_SSCIR7). This write sets a CLR n flag bit that generates an interrupt request. The interrupt request is cleared by writing a 1 to the CLR n bit. Specific behavior includes the following:

- Writing a 1 to SET n leaves SET n unchanged at 0 but sets the flag bit (CLR n bit).
- Writing a 0 to SET n has no effect.
- Writing a 1 to CLR n clears the flag (CLR n) bit.
- Writing a 0 to CLR n has no effect.
- If a 1 is written to a pair of SET n and CLR n bits at the same time, the flag (CLR n) is set, regardless of whether CLR n was asserted before the write.

The time from the write to the SET n bit to the time that the INTC starts to drive the interrupt request to the processor is four clocks.

10.4.1.3 Unique Vector for Each Interrupt Request Source

Each peripheral and software settable interrupt request is assigned a hardwired unique 9-bit vector. Software settable interrupts 0–7 are assigned vectors 0–7, respectively. The peripheral interrupt requests are assigned vectors 8 to as high as needed to cover all of the peripheral interrupt requests.

10.4.2 Priority Management

The asserted interrupt requests are compared to each other based on their PRIn values in INTC priority select registers (INTC_PSR0–INTC_PSR231). The result of that comparison also is compared to PRI in

INTC current priority register (INTC_CPR). The results of those comparisons are used to manage the priority of the ISR being executed by the processor. The LIFO also assists in managing that priority.

10.4.2.1 Current Priority and Preemption

The priority arbitrator, selector, encoder, and comparator submodules shown in [Figure 10-1](#) are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software settable interrupt request is higher than the current priority, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software settable interrupt request is generated for INTC interrupt acknowledge register (INTC_IACKR), and if in hardware vector mode, for the interrupt vector provided to the processor.

10.4.2.1.1 Priority Arbitrator Submodule

The priority arbitrator submodule compares all the priorities of all of the asserted interrupt requests, both peripheral and software settable. The output of the priority arbitrator submodule is the highest of those priorities. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the request selector submodule.

10.4.2.1.2 Request Selector Submodule

If only one interrupt request from the priority arbitrator submodule is asserted, then it is passed as asserted to the vector encoder submodule. If multiple interrupt requests from the priority arbitrator submodule are asserted, then only the one with the lowest vector is passed as asserted to the vector encoder submodule. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software settable interrupt requests.

10.4.2.1.3 Vector Encoder Submodule

The vector encoder submodule generates the unique 9-bit vector for the asserted interrupt request from the request selector submodule.

10.4.2.1.4 Priority Comparator Submodule

The priority comparator submodule compares the highest priority output from the priority arbitrator submodule with PRI in INTC_CPR. If the priority comparator submodule detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in INTC_CPR or the PRI value in INTC_CPR is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in INTC_CPR when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI_n in INTC_PSR $_n$ are zero does not cause a preemption because their PRI_n is not higher than PRI in INTC_CPR.

10.4.2.2 LIFO

The LIFO stores the preempted PRI values from the INTC_CPR. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the INTC_CPR does not need to be loaded from the INTC_CPR and

stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the INTC_CPR.

The PRI value in the INTC_CPR is pushed onto the LIFO when the INTC_IACKR is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode. The priority is popped into PRI in the INTC_CPR whenever the INTC_EOIR is written.

Although the INTC supports 16 priorities, an ISR executing with PRI in the INTC_CPR equal to 15 is not preempted. Therefore, the LIFO supports the stacking of 15 priorities. However, the LIFO is only 14 entries deep. An entry for a priority of 0 is not needed because of how pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 15 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO pop zeros if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

The LIFO is not memory mapped.

10.4.3 Details on Handshaking with Processor

10.4.3.1 Software Vector Mode Handshaking

10.4.3.1.1 Acknowledging Interrupt Request to Processor

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in [Figure 10-14](#). The INTC examines the peripheral and software settable interrupt requests. When it finds an asserted peripheral or software settable interrupt request with a higher priority than PRI in INTC current priority register (INTC_CPR), it asserts the interrupt request to the processor. The INTVEC field in INTC interrupt acknowledge register (INTC_IACKR) is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in [Section 10.1.4.1](#), "Software Vector Mode."

10.4.3.1.2 End-of-Interrupt Exception Handler

Before the interrupt exception handling completes, INTC end-of-interrupt register (INTC_EOIR) must be written. When it is written, the LIFO is popped so that the preempted priority is restored into PRI of the INTC_CPR. Before it is written, the peripheral or software settable flag bit must be cleared so that the peripheral or software settable interrupt request is negated.

NOTE

To ensure proper operation across all Power Architecture MCUs, execute an MBAR or MSYNC instruction between the access to clear the flag bit and the write to the INTC_EOIR.

When returning from the preemption, the INTC does not search for the peripheral or software settable interrupt request whose ISR was preempted. Depending on how much the ISR progressed, that interrupt request can no longer be asserted. When PRI in INTC_CPR is lowered to the priority of the preempted

ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software settable interrupt request at or below that priority does not cause a preemption. Instead, after the restoration of the preempted context, the processor returns to the instruction address that it was to next execute before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler’s prolog or epilog.

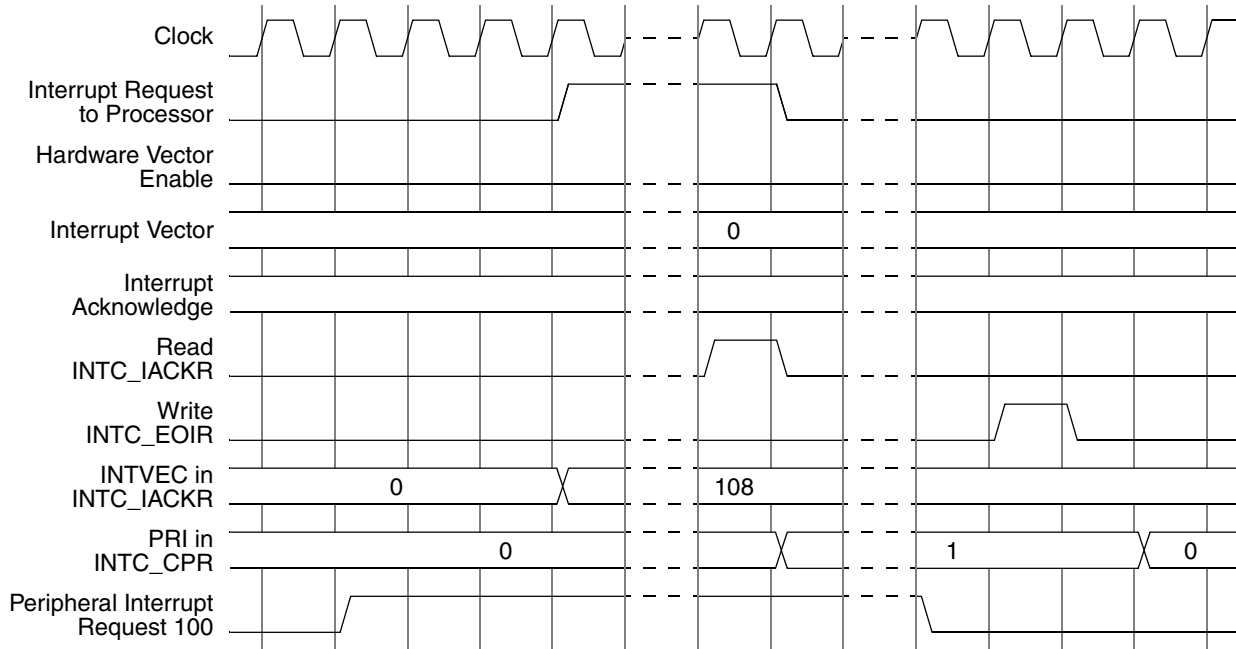

Figure 10-14. Software Vector Mode Handshaking Timing Diagram

10.4.3.2 Hardware Vector Mode Handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in [Figure 10-15](#). As in software vector mode, the INTC examines the peripheral and software settable interrupt requests, and when it finds an asserted one with a higher priority than PRI in INTC_CPR, it asserts the interrupt request to the processor. The INTVEC field in the INTC_IACKR is updated with the preempting peripheral or software settable interrupt request’s vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. In addition, the value of the interrupt vector to the processor matches the value of the INTVEC field in the INTC_IACKR. The rest of the handshaking is described in [Section 10.1.4.2, “Hardware Vector Mode.”](#)

The handshaking near the end of the interrupt exception handler, that is the writing to the INTC_EOIR, is the same as in software vector mode. Refer to [Section 10.4.3.1.2, “End-of-Interrupt Exception Handler.”](#)

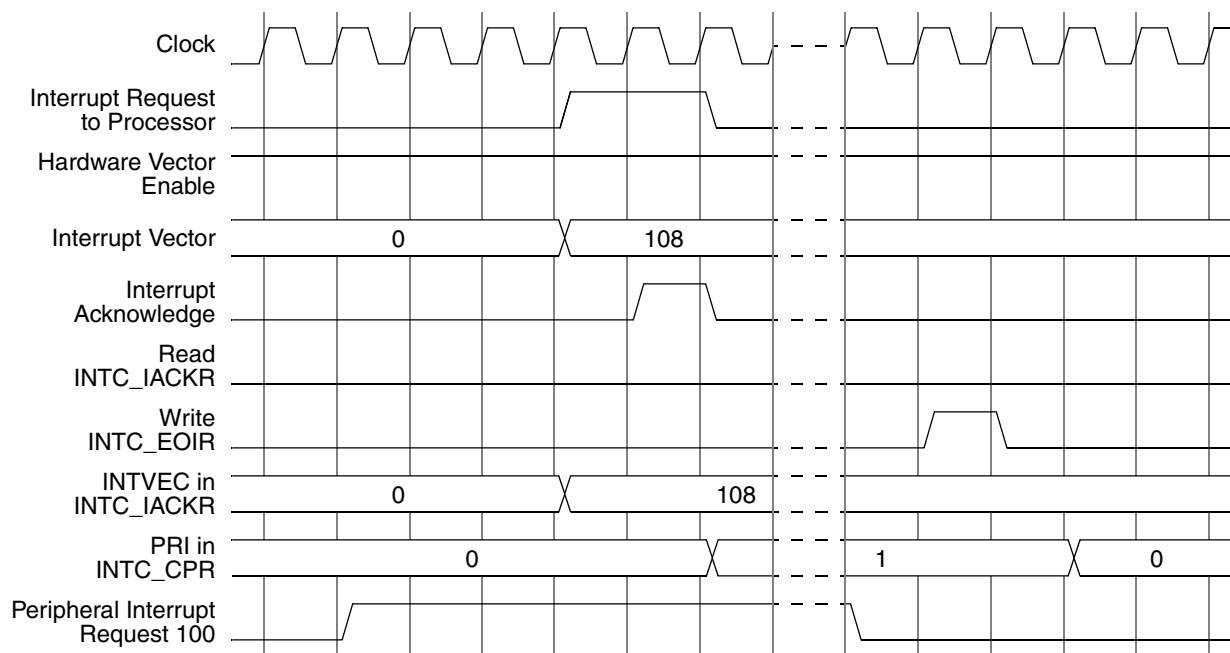

Figure 10-15. Hardware Vector Mode Handshaking Timing Diagram

10.5 Initialization/Application Information

10.5.1 Initialization Flow

After exiting reset, all of the PRI_n fields in INTC priority select registers (INTC_PSR0–INTC_PSR231) is zero, and PRI in INTC current priority register (INTC_CPR) is 15. These reset values prevent the INTC from asserting the interrupt request to the processor. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software settable interrupt requests to cause an interrupt request to the processor is:

```
interrupt_request_initialization:
configure VTES and HVEN in INTC_MCR
configure VTBA in INTC_IACKR
raise the  $PRI_n$  fields in INTC_PSR $n$ 
set the enable bits or clear the mask bits for the peripheral interrupt requests
lower PRI in INTC_CPR to zero
enable processor recognition of interrupts
```

10.5.2 Interrupt Exception Handler

These example interrupt exception handlers use Power Architecture assembly code.

10.5.2.1 Software Vector Mode

```

interrupt_exception_handler:
code to create stack frame, save working register, and save SRR0 and SRR1

lis    r3,INTC_IACKR@ha        # form adjusted upper half of INTC_IACKR address
lwz    r3,INTC_IACKR@l(r3)    # load INTC_IACKR, which clears request to processor

blr                                # return to epilog
    
```

10.5.2.2 Hardware Vector Mode

This interrupt exception handler is useful with processor and system bus implementations that support a hardware vector. This example assumes that each `interrupt_exception_handlerx` only has space for four instructions, and therefore a branch to `interrupt_exception_handler_continuedx` is needed.

```

interrupt_exception_handlerx:
b          interrupt_exception_handler_continuedx# 4 instructions available, branch to continue

interrupt_exception_handler_continuedx:
code to create stack frame, save working register, and save SRR0 and SRR1

wrteei    1                                # enable processor recognition of interrupts

code to save rest of context required by e500 EABI

bl        ISRx                             # branch to ISR for interrupt with vector x

epilog:
code to restore most of context required by e500 EABI

# Popping the LIFO after the restoration of most of the context and the disabling of processor
# recognition of interrupts eases the calculation of the maximum stack depth at the cost of
# postponing the servicing of the next interrupt request.
mbar                                           # ensure store to clear flag bit has completed
lis      r3,INTC_EOIR@ha                      # form adjusted upper half of INTC_EOIR address
li       r4,0x0                               # form 0 to write to INTC_EOIR
wrteei    0                                # disable processor recognition of interrupts
stw      r4,INTC_EOIR@l(r3)                  # store to INTC_EOIR, informing INTC to lower priority

code to restore SRR0 and SRR1, restore working registers, and delete stack frame

rfi

ISRx:
code to service the interrupt event
code to clear flag bit which drives interrupt request to INTC

blr                                           # branch to epilog

```

10.5.3 ISR, RTOS, and Task Hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC current priority register (INTC_CPR) having a value of 0. The RTOS execute the tasks according to whatever priority scheme that it has, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPR priority 0 and outside the control of the RTOS, the RTOS executes at INTC_CPR priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPR priority 0.

If a task shares a resource with an ISR and the PCP is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPR while the shared resource is being accessed.

An ISR whose PRI_n in INTC priority select registers (INTC_PSR0–INTC_PSR231) has a value of 0 does not cause an interrupt request to the processor, even if its peripheral or software settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit causes it to remain negated, which consequently also does not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR does not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

10.5.4 Order of Execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software settable interrupt requests. However, if multiple peripheral or software settable interrupt requests are asserted, more than one has the highest priority, and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software settable interrupt requests asserted.

The example in [Table 10-10](#) shows the order of execution of both ISRs with different priorities, and with the same priority.

Table 10-10. Order of ISR Execution Example

Step	Step Description	Code Executing At End of Step					Interrupt Exception Handler	PRI in INTC_CPR at End of Step
		RTOS	ISR108 ¹	ISR208	ISR308	ISR408		
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 is asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 is asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 is asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIR.						X	1
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3

Table 10-10. Order of ISR Execution Example (continued)

Step	Step Description	Code Executing At End of Step					Interrupt Exception Handler	PRI in INTC_CPR at End of Step
		RTOS	ISR108 ¹	ISR208	ISR308	ISR408		
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR.						X	0
12	RTOS continues execution.	X						0

¹ ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software settable interrupt requests.

10.5.5 Priority Ceiling Protocol

10.5.5.1 Elevating Priority

The PRI field in INTC current priority register (INTC_CPR) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR to 3, the ceiling of all of the ISR priorities. After they release the resource, the PRI value in INTC_CPR can be lowered. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR can not release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

10.5.5.2 Ensuring Coherency

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible that both of these stores are executed. ISR2 thereby thinks that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR can be made by those system services with the following code sequences.

```
GetResource:  
raise PRI  
mbar  
isync  
ReleaseResource:  
mbar  
lower PRI
```

10.5.6 Selecting Priorities According to Request Rates and Deadlines

The selection of the priorities for the ISRs can be made using rate monotonic scheduling (RMS) or a superset of it, deadline monotonic scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 μ s, ISR2 executes every 200 μ s, and ISR3 executes every 300 μ s. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 μ s, then it has a higher priority than ISR2.

The INTC has 16 priorities, which could be much less than the number of ISRs. In this case, group the ISRs with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 μ s would share a priority, ISRs with request rates around 250 μ s would share a priority, etc. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does reduce the processor's ability to meet its deadlines. However, it also allows easier management of ISRs with similar deadlines that share a resource. They do not need to use the PCP to access the shared resource.

10.5.7 Software Settable Interrupt Requests

The software settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

10.5.7.1 Scheduling a Lower Priority Portion of an ISR

A portion of an ISR needs to be executed at the PRI_n value in INTC priority select registers (INTC_PSR0–INTC_PSR231), which becomes the PRI value in INTC current priority register (INTC_CPR) with the interrupt acknowledgement. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority

than the earlier portion of the ISR but do have a higher priority than what the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a $SETn$ bit in INTC software set/clear interrupt registers (INTC_SSCIR0–INTC_SSCIR7). Writing a 1 to $SETn$ causes a software settable interrupt request. This software settable interrupt request, which usually has a lower PRI_n value in the INTC_PSR n , therefore does not cause preemptive scheduling inefficiencies.

After generating a software settable interrupt request, the higher priority ISR completes. The lower priority ISR is scheduled according to its priority. Execution of the higher priority ISR is not resumed after the completion of the lower priority ISR.

10.5.7.2 Scheduling an ISR on Another Processor

Since the $SETn$ bits in the INTC_SSCIR n are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One application is that one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor is concerned that processor executing the software settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR n bit in INTC_SSCIR n is asserted before again writing a 1 to the $SETn$ bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a $SETn$ bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR n bit and then writes 1 to a $SETn$ bit on the first processor, informing it that it now can access the block of data.

10.5.8 Lowering Priority Within an ISR

In implementations without the software-settable interrupt requests in the INTC software set/clear interrupt registers (INTC_SSCIR0–INTC_SSCIR7), a way — besides scheduling a task through an RTOS — to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in [Section 10.5.7.1, “Scheduling a Lower Priority Portion of an ISR,”](#)) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

NOTE

Lowering the PRI value in INTC current priority register (INTC_CPR) within an ISR to below the ISR's corresponding PRI value in INTC priority select registers (INTC_PSR0–INTC_PSR231) allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

10.5.9 Negating an Interrupt Request Outside of its ISR

10.5.9.1 Negating an Interrupt Request as a Side Effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negating of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

10.5.9.2 Negating Multiple Interrupt Requests in One ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

10.5.9.3 Proper Setting of Interrupt Request Priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing a flag bit, the priorities of the peripheral or software settable interrupt requests for these other flag bits must be selected properly. Their PRI_n values in INTC priority select registers (INTC_PSR0–INTC_PSR231) must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC end-of-interrupt register (INTC_EOIR) as the clearing of the flag bit that caused the present ISR to be executed. Refer to [Section 10.4.3.1.2, “End-of-Interrupt Exception Handler,”](#) for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request’s PRI_n value in INTC_PSR n .

10.5.10 Examining LIFO contents

Normally you do not need to know the contents of the LIFO, or even how deep the LIFO is nested. Although the LIFO contents are not memory mapped, you can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR). Disabling processor recognition of interrupts while examining the LIFO contents provides a coherent view of the preempted priorities.

The code sequence is:

```
pop_lifo:
store to INTC_EOIR
load INTC_CPR, examine PRI, and store onto stack
if PRI is not zero or value when interrupts were enabled, branch to pop_lifo
```

When you are finished examining the LIFO contents, you can restore it in software vector mode using the following code sequence. In hardware vector mode, reading the INTC_IACKR does not push the INTC_CPR[PRI] onto the LIFO, therefore the LIFO contents cannot be restored in hardware vector mode.

```
push_lifo:
load stacked PRI value and store to INTC_CPR
load INTC_IACKR
if stacked PRI values are not depleted, branch to push_lifo
```

NOTE

Reading the INTC_IACKR acknowledges the interrupt request to the processor and updates the INTC_CPR[PRI] with the priority of the preempting interrupt request. If the processor recognition of interrupts is disabled during the LIFO restoration, interrupt requests to the processor can go undetected. However, since the peripheral or software settable interrupt requests are not cleared, the peripheral interrupt request to the processor re-asserts when INTC_CPR[PRI] is lower than the priorities of those peripheral or software settable interrupt requests.

10.6 Document Revision History

Table 10-11. Changes Between MPC5565RM Revisions 0.1 and 1

<p>Changed the NOTE at the end of Section 10.4.1, "Interrupt Request Sources:</p> <ul style="list-style-type: none"> • From: "In this case, the interrupt vector will correspond..." • To: "If the interrupt request to the processor does assert or does remain asserted, the interrupt vector will correspond..."
<p>In Section 10.5.10, "Examining LIFO contents:</p> <p>Removed: "Normally the user does not need to know the contents of the LIFO. One may not even know how deeply the LIFO is nested. However, if one should want to read the contents, such as in debug mode, they are not memory mapped. The contents still can be read by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR). The code sequence is:</p> <pre>pop_lifo: store to INTC_EOIR load INTC_CPR, examine PRI, and store onto stack if PRI is not zero or value when interrupts were enabled, branch to pop_lifo</pre> <p>When the examination is complete, the LIFO can be restored using this code sequence:</p> <pre>push_lifo: load stacked PRI value and store to INTC_CPR load INTC_IACKR if stacked PRI values are not depleted, branch to push_lifo</pre>

Table 10-11. Changes Between MPC5565RM Revisions 0.1 and 1 (continued)

In Section 10.5.10, "Examining LIFO contents:"

Added: "Normally you do not need to know the contents of the LIFO, or even how deep the LIFO is nested. Although the LIFO contents are not memory mapped, you can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR). Disabling processor recognition of interrupts while examining the LIFO contents provides a coherent view of the preempted priorities. The code sequence is:

```
pop_lifo:
store to INTC_EOIR
load INTC_CPR, examine PRI, and store onto stack
if PRI is not zero or value when interrupts were enabled, branch to pop_lifo
```

When you are finished examining the LIFO contents, you can restore it in software vector mode using the following code sequence. In hardware vector mode, reading the INTC_IACKR does not push the INTC_CPR[PRI] onto the LIFO, therefore the LIFO contents cannot be restored in hardware vector mode.

```
push_lifo:
load stacked PRI value and store to INTC_CPR
load INTC_IACKR
if stacked PRI values are not depleted, branch to push_lifo
```

NOTE

Reading the INTC_IACKR acknowledges the interrupt request to the processor and updates the INTC_CPR[PRI] with the priority of the preempting interrupt request. If the processor recognition of interrupts is disabled during the LIFO restoration, interrupt requests to the processor can go undetected. However, since the peripheral or software settable interrupt requests are not cleared, the peripheral interrupt request to the processor re-asserts when INTC_CPR[PRI] is lower than the priorities of those peripheral or software settable interrupt requests.

Throughout the chapter, replaced "priority inversion" with "scheduling inefficiencies" as follows:

Section 10.5.5.1, "Elevating Priority

- From: "After they release the resource, they must lower the PRI value in INTC_CPR to prevent further priority inversion."
- To: "After they release the resource, the PRI value in INTC_CPR can be lowered."
- From: "Using the PCP instead of disabling processor recognition of all interrupts reduces the priority inversion time when accessing a shared resource."
- To: "Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked."

Section 10.5.6, "Selecting Priorities According to Request Rates and Deadlines

Added the acronyms RMS and DMS for 'rate monotonic scheduling' and 'deadline monotonic scheduling.'

- From: "Reducing the number of priorities does cause some priority inversion which reduces the processor's ability to meet its deadlines. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource"
- To: "Reducing the number of priorities does reduce the processor's ability to meet its deadlines. However, it also allows easier management of ISRs with similar deadlines that share a resource. They do not need to use the PCP to access the shared resource."

Section 10.5.7.1, "Scheduling a Lower Priority Portion of an ISR

- From: "Therefore, executing this later portion which does not need to be executed at this higher priority can block the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than what the later portion of the ISR needs. This priority inversion reduces the processor's ability to meet its deadlines."
- To: "Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than what the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines."
- From: "This software settable interrupt request, which usually will have a lower PRIn value in the INTC_PSRn, therefore will not cause priority inversion."
- To: "This software settable interrupt request, which usually will have a lower PRIn value in the INTC_PSRn, therefore will not cause preemptive scheduling inefficiencies."

Table 10-11. Changes Between MPC5565RM Revisions 0.1 and 1 (continued)

<p>Section 10.5.8, “Lowering Priority Within an ISR</p> <ul style="list-style-type: none"> From: “the only way (besides scheduling a task through an RTOS) to prevent priority inversion with an ISR whose work spans multiple priorities” To: “a way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities” From: “Therefore, the INTC does not support lowering the current priority within an ISR as a way to avoid priority inversion.” To: “Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.”
<p>Corrected register name from EIISR to EISR in Interrupt Request Sources table.</p>
<p>Added this sentence to “Scheduling a Lower Priority ...” section:</p> <ul style="list-style-type: none"> “After generating a software settable interrupt request, the higher priority ISR completes. The lower priority ISR is scheduled according to its priority. Execution of the higher priority ISR is not resumed after the completion of the lower priority ISR”
<p>Table 10-9 Combined adjacent reserved areas of memory.</p>
<p>Figure 10-1 <i>INT Block Diagram</i>: Changed key for diagram from : ‘Non-memory mapped logic’ to: Logic not memory-mapped. Variables set for another product. Changed footnote 1</p> <p>From: The total number of interrupt sources is 332, which includes 26 reserved source and 8 software sources</p> <p>To: Although N (maximum number of addressable IRQ vectors) = 231, the total number of interrupts must be a multiple of four. Therefore, the total number of interrupts is 232: 208 peripheral IRQs, 8 software-configurable IRQs, and 16 reserved IRQs</p>
<p>Figure 10-3 <i>Program Flow–Software Vector Mode</i>: Added footnote 1 in text frame inside figure that reads:</p> <p>N is the maximum number of usable interrupt vectors. which equals 231, and includes 16 reserved IRQ vectors and eight software-settable IRQ vectors. Because the memory is mapped in four-byte words, the total number of interrupt vectors must be a multiple of four, therefore one more interrupt vector exists to complete the word. This results in a total of 232 interrupt vectors. However, interrupt vector 232 is reserved and not available.</p>
<p>Figure 10-4 <i>Program Flow–Hardware Vector Mode</i>: Added two notes that read:</p> <p>Address IVPR + 0x12C0 contains the 231 interrupt vector and is the last usable interrupt vector address in the interrupt memory map for this device.</p> <p>and</p> <p>N is the maximum number of usable interrupt vectors. which equals 231(address is IVPR + 0x12C0), and includes 16 reserved IRQ vectors and eight software-settable IRQ vectors. Because the memory is mapped in four-byte words, the total number of interrupt registers must be a multiple of four, therefore another interrupt vector exists in memory to complete the word for a total of 232 interrupt vectors. However, the 232 interrupt vector is reserved and is not available.</p>
<p>Section 10.1.3, “Features”: Added page footnote to first bullet: Although N (maximum number of addressable IRQ vectors) = 231, the total number of interrupts must be a multiple of four. Therefore, the total number of interrupts is 232: 208 peripheral IRQs, 8 software-configurable IRQs, and 16 reserved.</p>
<p>Table 10-9 <i>MPC5565 Interrupt Sources</i>: Added to column two heading ‘Number’ after ‘vector’ and table footnote 1 that reads: The vector number is used to identify the interrupt and does not indicate the maximum number of usable interrupt sources.</p>

Chapter 11

Frequency Modulated Phase Locked Loop and System Clocks (FMPLL)

11.1 Introduction

This section describes the features and function of the FMPLL module.

11.1.1 Block Diagrams

This section contains block diagrams that illustrate the FMPLL, the clock architecture, and the various FMPLL and clock configurations that are available. The following diagrams are provided:

- [Figure 11-1](#), “FMPLL and Clock Architecture”
- [Figure 11-2](#), “FMPLL Bypass Mode”
- [Figure 11-3](#), “FMPLL External Reference Mode”
- [Figure 11-4](#), “FMPLL Crystal Reference Mode Without FM”
- [Figure 11-5](#), “FMPLL Crystal Reference Mode With FM”
- [Figure 11-6](#), “FMPLL Dual-Controller (1:1) Mode”

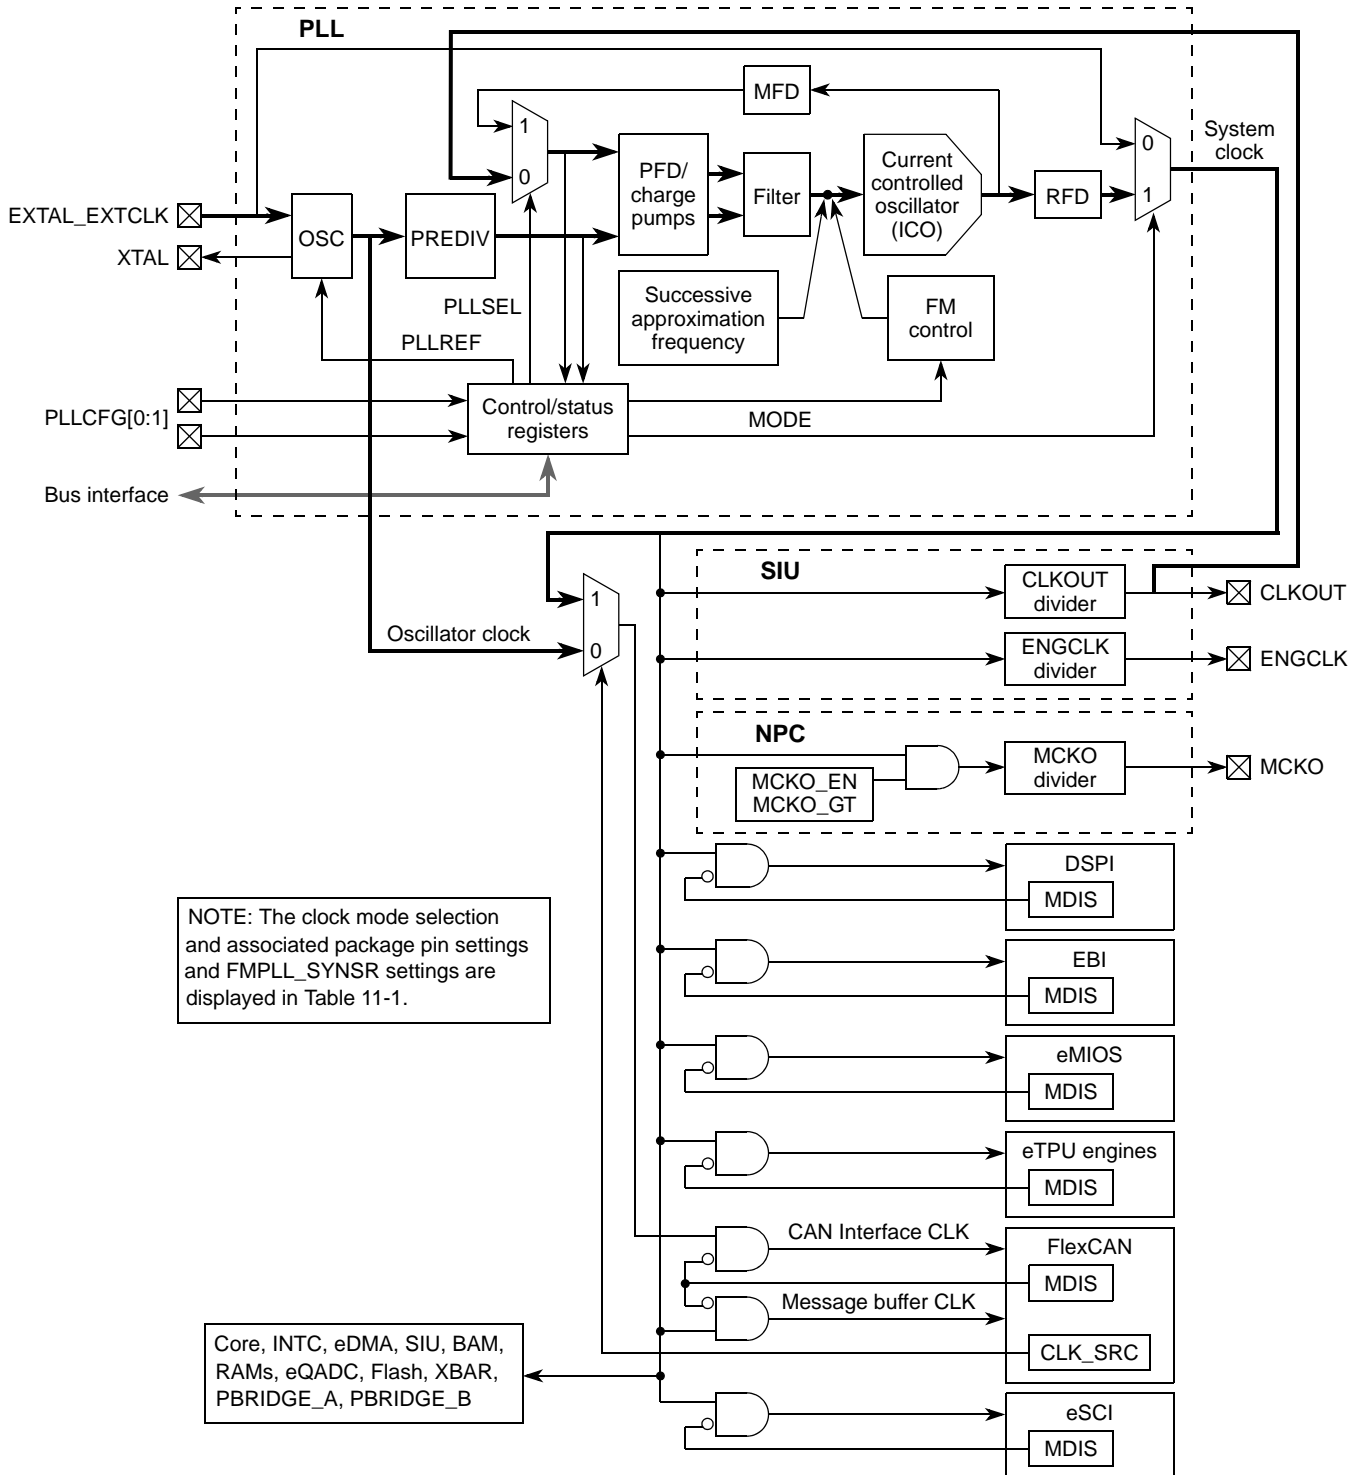

Figure 11-6. FMPLL Dual Controller (1:1) Mode

11.1.2 Overview

The frequency modulated phase locked loop (FMPLL) allows the user to generate high speed system clocks from an 8–20 MHz crystal oscillator or from an external clock generator. Further, the FMPLL supports programmable frequency modulation of the system clock. The FMPLL multiplication factor, reference clock pre-divider factor, output clock divider ratio, modulation depth, and modulation rate are all controllable through a bus interface.

11.1.3 Features

The FMPLL has the following major features:

- Input clock frequency from 8–20 MHz
- Current controlled oscillator (ICO) range from 48 MHz to maximum device frequency
- Reference frequency pre-divider (PREDIV) for finer frequency synthesis resolution
- Reduced frequency divider (RFD) for reduced frequency operation without forcing the FMPLL to re-lock
- Four modes of operation:
 - Bypass mode.
 - Crystal reference mode. This is the default mode for the 324 (with or without the 496 assembly) package. Refer to [Section 11.1.4.1, “Crystal Reference \(Default Mode\).”](#)
 - External reference mode. Refer to [Section 11.1.4.2, “External Reference Mode.”](#)
 - PLL dual-controller (1:1) mode for EXTAL_EXTCLK to CLKOUT skew minimization.
- Programmable frequency modulation
 - Modulation enabled/disabled via bus interface
 - Triangle wave modulation
 - Register programmable modulation depth ($\pm 1\%$ to $\pm 2\%$ deviation from center frequency)
 - Register programmable modulation frequency dependent on reference frequency; limited to 100–250 MHz.
- Lock detect circuitry reports when the FMPLL has achieved frequency lock and continuously monitors lock status to report loss of lock conditions
 - User-selectable ability to generate an interrupt request upon loss of lock. Refer to [Chapter 10, “Interrupt Controller \(INTC\),”](#) for details.
 - User-selectable ability to generate a system reset upon loss of lock. Refer to [Chapter 4, “Reset,”](#) for details.
- Loss-of-clock (LOC) detection for reference and feedback clocks
 - User-selectable ability to generate an interrupt request upon loss of clock. Refer to [Chapter 10, “Interrupt Controller \(INTC\),”](#) for details.
 - User-selectable ability to generate a system reset upon loss of clock. Refer to [Chapter 4, “Reset,”](#) for details.
- Self-locked mode (SCM) operation in event of input clock failure

11.1.4 FMPLL Modes of Operation

The FMPLL operational mode is configured during reset. For devices in the 324 (with or without the 496 assembly) package, the FMPLL operating mode defaults to crystal reference mode. If you change the FMPLL to a different mode for devices that use these packages, the $\overline{\text{RSTCFG}}$ and PLLCFG[0:1] package pins must be driven to the state for the new mode from the time $\overline{\text{RSTOUT}}$ asserts until it negates. As shown in Table 11-3, if $\overline{\text{RSTCFG}}$ is not asserted during reset, the state of the PLLCFG package pins is ignored, and the FMPLL operates in the default crystal reference mode. The table also shows that to enter any other mode, $\overline{\text{RSTCFG}}$ must be asserted during reset.

Table 11-1 shows clock mode selection during reset configuration for the 324 (with or without the 496 assembly) pin package. Additional information on reset configuration options for the FMPLL are in Chapter 4, “Reset.”

Table 11-1. Clock Mode Selection in 324 (with or without the 496 assembly) Package

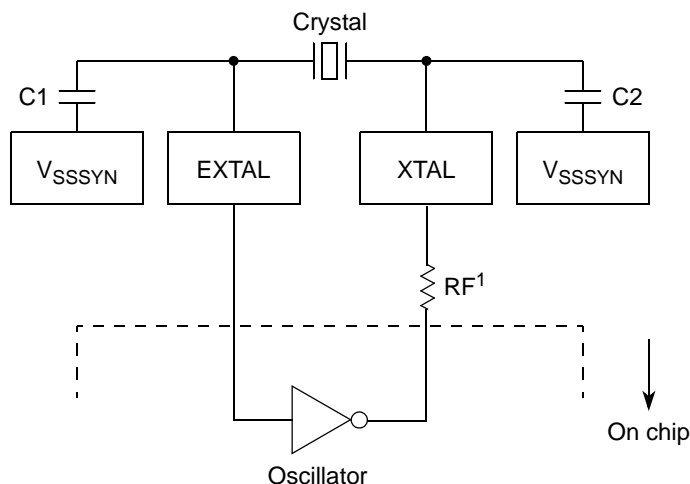

Clock Mode	Package Pins			Synthesizer Status Register (FMPLL_SYNSR) ¹ Bits		
	$\overline{\text{RSTCFG}}$	PLLCFG[0]	PLLCFG[1]	MODE	PLLSEL	PLLREF
Crystal reference (default mode)	1	PLLCFG pins ignored.		1	1	1
	0	1	0			
External reference	0	0	1	1	1	0
Bypass mode	0	0	0	0	0	0
Dual-controller mode	0	1	1	1	0	0

¹ Refer to Section 11.3.1.2, “Synthesizer Status Register (FMPLL_SYNSR)” for more information on these bits.

11.1.4.1 Crystal Reference (Default Mode)

In crystal reference mode, the FMPLL receives an input clock frequency ($F_{\text{ref_crystal}}$) from the crystal oscillator circuit (EXTAL_EXTCLK) and the pre-divider, and multiplies the frequency to create the FMPLL output clock. The user must supply a crystal oscillator that is within the appropriate input frequency range, the crystal manufacture’s recommended external support circuitry, and a short signal route from the MCU to the crystal.

The external support circuitry for the crystal oscillator is shown in Figure 11-7. Example component values are shown as well. Note that the actual circuit should be reviewed with the crystal manufacturer. A block diagram illustrating crystal reference mode is shown in Figure 11-4.

¹ For an 8–20 MHz crystal, the resistor must be 1–2.8KΩ. For a 40 MHz crystal, the resistor must be approximately 500Ω. The exact value depends on the crystal characteristics, thus consult the crystal manufacturer.

Figure 11-7. Crystal Oscillator Network

In crystal reference mode, the FMPLL can generate a frequency modulated clock or a non-modulated clock (locked on a single frequency). The modulation rate, modulation depth, output clock divide ratio (RFD), and whether the FMPLL is modulating or not can be programmed by writing to the FMPLL registers. Crystal reference is the default clock mode for the 324 pin package. It is not necessary to force PLLCFG[0:1] to enter this mode.

Tying the PLLCFG[2] signal low is required to operate in the 8–20 MHz range. Refer to FMPLL_SYNCNCR[PREDIV].

11.1.4.2 External Reference Mode

This external reference mode functions the same as crystal reference mode except that EXTAL_EXTCLK is driven by an external clock generator rather than a crystal oscillator. Also, the input frequency range (F_{ref_ext}) in external reference mode is the same as the input frequency reference range ($F_{ref_crystal}$) in the crystal reference mode; frequency modulation is available. To enter external reference mode, the default FMPLL configuration must be overridden by following the procedure outlined in [Section 11.1.4, “FMPLL Modes of Operation.”](#) A block diagram illustrating external reference mode is shown in [Figure 11-3.](#)

NOTE

In addition to supplying power for the CLKOUT signal, when the FMPLL is configured for external reference mode of operation, the V_{DDE5} supply voltage also controls the voltage level at which the signal presented to the EXTAL_EXTCLK pin causes a switch in the clock logic levels. The EXTAL_EXTCLK accepts a clock source with a voltage range of 1.6–3.6 V, however the transition voltage is determined by V_{DDE5} supply voltage divided by two. As an example, if V_{DDE5} is 3.3 V, then the clock transitions at approximately 1.6 V. The V_{DDE5} supply voltage and the voltage level of the external clock reference must be compatible, or the device does not clock properly.

11.1.4.3 Bypass Mode

In FMPLL bypass mode, the FMPLL is completely bypassed and the user must supply an external clock on the EXTAL_EXTCLK pin. The external clock is used directly to produce the internal system clocks. In bypass mode, the analog portion of the FMPLL is disabled and no clocks are generated at the FMPLL output. Consequently, frequency modulation is not available. In bypass mode the pre-divider is bypassed and has no effect on the system clock. The frequency in bypass mode is F_{ref_ext} .

To enter bypass mode, the default FMPLL configuration must be overridden by following the procedure outlined in [Section 11.1.4, “FMPLL Modes of Operation.”](#) A block diagram illustrating bypass mode is shown in [Figure 11-2](#).

11.1.4.4 Dual-Controller Mode (1:1)

FMPLL dual-controller mode is used by the slave MCU device of a dual-controller system. The slave FMPLL facilitates skew reduction between the input and output clock signals. To enter dual-controller mode, the default FMPLL configuration must be overridden by the procedure outlined in [Section 11.1.4, “FMPLL Modes of Operation.”](#)

In this mode, the system clock runs at twice the frequency of the EXTAL_EXTCLK input pin and is phase aligned. Note that crystal operation is not supported in dual-controller mode and an external clock must be provided. In this mode, the frequency and phase of the signal at the EXTAL_EXTCLK pin and the CLKOUT pin of the slave MCU are matched. A block diagram illustrating dual-controller mode (1:1) is shown in [Figure 11-6](#).

Frequency modulation is not available when configured for dual-controller mode for both the master and slave devices. Enabling frequency modulation on the device supplying the reference clock to the slave in dual-controller mode produces unreliable clocks on the slave.

NOTE

When configured for dual-controller mode, the CLKOUT clock divider on the slave device must not be changed from its reset state of divide-by-two. Increasing or decreasing this divide ratio produces unpredictable results from the FMPLL.

11.2 External Signal Description

Table 11-2 lists external signals used by the FMPLL during normal operation.

Table 11-2. PLL External Pin Interface

Name	I/O Type	Function	Pull
PLLCFG[0]_GPIO[208]	I/O	Configures the mode during reset. GPIO used otherwise.	Up
PLLCFG[1]_GPIO[209]	I/O	Configures the mode during reset. GPIO used otherwise.	Up
PLLCFG[2] ¹	I	Configures the crystal oscillator range	—
XTAL	Output	Output drive for external crystal	—
EXTAL_EXTCLK	Input	Crystal/external clock input	—
V _{DDSYN}	Power	Analog power supply (3.3 V ±10%)	—
V _{SSSYN}	Ground	Analog ground	—

¹ In the MPC5565, tie PLLCFG[2] to ground.

11.3 Memory Map/Register Definition

Table 11-3 shows the FMPLL memory map locations.

Table 11-3. FMPLL Module Memory Map

Address	Register Name	Register Description	Bits
Base (0xC3F8_0000)	FMPLL_SYNCR	Synthesizer control register	32
Base + 0x0004	FMPLL_SYNSR	Synthesizer status register	32
Base + 0x0008–0xC3F8_3FFF	—	Reserved	—

11.3.1 Register Descriptions

The clock operation is controlled by the synthesizer control register (FMPLL_SYNCR) and status is reported in the synthesizer status register (FMPLL_SYNSR). The following sections describe these registers in detail.

11.3.1.1 Synthesizer Control Register (FMPLL_SYNCR)

The synthesizer control register (FMPLL_SYNCR) contains bits for defining the clock operation for the system.

NOTE

To ensure proper operation for all MPC5500s, execute an **mbar** or **msync** instruction between: the write to change the FMPLL_SYNCR[MFD], and the read to check the lock status shown by FMPLL_SYNSR[LOCK].

Buffered writes to the FMPLL, as controlled by PBRIDGE_A_OPACR[BW0], must be disabled.

Address: Base + 0x0000

Access: User R/W

Figure 11-8. Synthesizer Control Register (FMPLL_SYNCR)

Table 11-4. FMPLL_SYNCR Field Descriptions

Field	Description
0	Reserved.
1–3 PREDIV[0:2]	<p>The PREDIV bits control the value of the divider on the input clock. The output of the pre-divider circuit generates the reference clock (F_{prediv}) to the FMPLL analog loop. When the PREDIV bits are changed, the FMPLL immediately loses lock. To prevent an immediate reset, the LOLRE bit must be cleared before writing the PREDIV bits. In 1:1 (dual-controller) mode, the PREDIV bits are ignored and the input clock is fed directly to the analog loop.</p> <p>000 Divide by 1 001 Divide by 2 010 Divide by 3 011 Divide by 4 100 Divide by 5 101–111 Invalid values</p> <p>Note: Programming a PREDIV value such that the ICO operates outside its specified range causes unpredictable results and the FMPLL does not lock. Refer to the device <i>Data Sheet</i> for details on the ICO range.</p> <p>Note: To avoid unintentional interrupt requests, disable LOLIRQ before changing PREDIV and then reenables it after acquiring lock.</p> <p>Note: When using crystal reference mode or external reference mode, The PREDIV value must not be set to any value that causes the phase/frequency detector to go below 4 MHz. That is, the crystal ($F_{ref_crystal}$) or external clock (F_{ref_ext}) frequency divided by the PREDIV value creates the F_{prediv} frequency that must be greater than or equal to 4–20 MHz. Refer to the device <i>Data Sheet</i> for F_{prediv} values.</p> <p>Note: To use the 8–20 MHz OSC, the PLL predivider must be configured for divide-by-two operation by tying PLLCFG2 low (set PREDIV to 0b000).</p>

Table 11-4. FMPLL_SYNCR Field Descriptions (continued)

Field	Description																		
4–8 MFD[0:4]	<p>Multiplication factor divider. The MFD bits control the value of the divider in the FMPLL feedback loop. The value specified by the MFD bits establish the multiplication factor applied to the reference frequency. The decimal equivalent of the MFD binary number is substituted into the equation from Table 11-9 for F_{sys} to determine the equivalent multiplication factor.</p> <p>When the MFD bits are changed, the FMPLL loses lock. At this point, if modulation is enabled, the calibration sequence is reinitialized. To prevent an immediate reset, the LOLRE bit must be cleared before writing the MFD bits. In dual-controller mode, the MFD bits are ignored and the multiplication factor is equivalent to 2X. In bypass mode the MFD bits have no effect.</p> <p>Note: Programming an MFD value such that the ICO operates outside its specified range causes unpredictable results and the FMPLL does not lock. Refer to the device <i>Data Sheet</i> for details on the ICO range.</p> <p>Note: To avoid unintentional interrupt requests, disable LOLIRQ before changing MFD and then reenables it after acquiring lock.</p>																		
9	Reserved.																		
10–12 RFD[0:2]	<p>Reduced frequency divider. The RFD bits control a divider at the output of the FMPLL. The value specified by the RFD bits establish the divisor applied to the FMPLL frequency.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>RFD[0:2]</th> <th>Output Clock Divide Ratio</th> </tr> </thead> <tbody> <tr> <td>000</td> <td>Divide by 1</td> </tr> <tr> <td>001</td> <td>Divide by 2</td> </tr> <tr> <td>010</td> <td>Divide by 4</td> </tr> <tr> <td>011</td> <td>Divide by 8</td> </tr> <tr> <td>100</td> <td>Divide by 16</td> </tr> <tr> <td>101</td> <td>Divide by 32</td> </tr> <tr> <td>110</td> <td>Divide by 64</td> </tr> <tr> <td>111</td> <td>Divide by 128</td> </tr> </tbody> </table> <p>Changing the RFD bits does not affect the FMPLL; hence, no re-lock delay is incurred. Resulting changes in clock frequency are synchronized to the next falling edge of the current system clock. However these bits must only be written when the lock bit (LOCK) is set, to avoid exceeding the allowable system operating frequency. In bypass mode, the RFD bits have no effect.</p>	RFD[0:2]	Output Clock Divide Ratio	000	Divide by 1	001	Divide by 2	010	Divide by 4	011	Divide by 8	100	Divide by 16	101	Divide by 32	110	Divide by 64	111	Divide by 128
RFD[0:2]	Output Clock Divide Ratio																		
000	Divide by 1																		
001	Divide by 2																		
010	Divide by 4																		
011	Divide by 8																		
100	Divide by 16																		
101	Divide by 32																		
110	Divide by 64																		
111	Divide by 128																		
13 LOCEN	<p>Loss-of-clock enable. The LOCEN bit determines whether the loss of clock function is operational. Refer to Section 11.4.2.6, “Loss-of-Clock Detection” and Section 11.4.2.6.1, “Alternate/Backup Clock Selection” for more information.</p> <p>In bypass mode, this bit has no effect.</p> <p>LOCEN does not affect the loss of lock circuitry.</p> <p>0 Loss of clock disabled. 1 Loss of clock enabled.</p>																		

Table 11-4. FMPLL_SYNCR Field Descriptions (continued)

Field	Description								
14 LOLRE	<p>Loss-of-lock reset enable. The LOLRE bit determines how the integration module (the SIU) handles a loss of lock indication. When operating in crystal reference, external reference, or dual-controller mode, the FMPLL must be locked before setting the LOLRE bit. Otherwise reset is immediately asserted. The LOLRE bit has no effect in bypass mode.</p> <p>0 Ignore loss of lock, reset not asserted. 1 Assert reset on loss of lock. Reset remains asserted, regardless of the source of reset, until after the FMPLL has locked.</p>								
15 LOCRE	<p>Loss-of-clock reset enable. The LOCRE bit determines how the integration module (the SIU) handles a loss of clock condition when LOCEN = 1. LOCRE has no effect when LOCEN = 0. If the LOCF bit in the SYNCR indicates a loss of clock condition, setting the LOCRE bit causes an immediate reset. In bypass mode LOCRE has no effect.</p> <p>0 Ignore loss of clock, reset not asserted. 1 Assert reset on loss of clock.</p>								
16 DISCLK	<p>Disable CLKOUT. The DISCLK bit determines whether CLKOUT is active. When CLKOUT is disabled it is driven low.</p> <p>0 CLKOUT driven normally 1 CLKOUT driven low</p>								
17 LOLIRQ	<p>Loss-of-lock interrupt request. The LOLIRQ bit enables an interrupt request for LOLF when it (LOLIRQ) is asserted and when LOLF is asserted. If either LOLF or LOLIRQ is negated, the interrupt request is negated. When operating in crystal reference, external reference, or dual-controller mode, the FMPLL must be locked before setting the LOLIRQ bit. Otherwise an interrupt is immediately requested. The LOLIRQ bit has no effect in bypass mode</p> <p>0 Ignore loss of lock, interrupt not requested 1 Request interrupt</p>								
18 LOCIRQ	<p>Loss-of-clock interrupt request. The LOCIRQ bit determines how the integration module (the SIU) handles a loss of clock condition when LOCEN = 1. LOCIRQ has no effect when LOCEN = 0. If the LOCF bit in the SYNCR indicates a loss of clock condition, setting (or having previously set) the LOCIRQ bit causes an interrupt request. In bypass mode LOCIRQ has no effect.</p> <p>0 Ignore loss of clock, interrupt not requested 1 Request interrupt on loss of clock.</p>								
19 RATE	<p>Modulation rate. Controls the rate of frequency modulation applied to the system frequency. The allowable modulation rates are shown below. Changing the rate by writing to the RATE bit initiates the FM calibration sequence.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>RATE</th> <th>Modulation Rate (Hz)</th> </tr> </thead> <tbody> <tr> <td rowspan="2">0</td> <td>$F_{mod} = F_{ref_crystal} / (PREDIV + 1) 80$</td> </tr> <tr> <td>$F_{mod} = F_{ref_ext} / (PREDIV + 1) 80$</td> </tr> <tr> <td rowspan="2">1</td> <td>$F_{mod} = F_{ref_crystal} / (PREDIV + 1) 40$</td> </tr> <tr> <td>$F_{mod} = F_{ref_ext} / (PREDIV + 1) 40$</td> </tr> </tbody> </table> <p>Note: To avoid unintentional interrupt requests, clear LOLIRQ before changing RATE. Note: F_{mod} must be between 100–250 MHz. Refer to Section 11.4.3.2, “Programming System Clock Frequency with Frequency Modulation.”</p>	RATE	Modulation Rate (Hz)	0	$F_{mod} = F_{ref_crystal} / (PREDIV + 1) 80$	$F_{mod} = F_{ref_ext} / (PREDIV + 1) 80$	1	$F_{mod} = F_{ref_crystal} / (PREDIV + 1) 40$	$F_{mod} = F_{ref_ext} / (PREDIV + 1) 40$
RATE	Modulation Rate (Hz)								
0	$F_{mod} = F_{ref_crystal} / (PREDIV + 1) 80$								
	$F_{mod} = F_{ref_ext} / (PREDIV + 1) 80$								
1	$F_{mod} = F_{ref_crystal} / (PREDIV + 1) 40$								
	$F_{mod} = F_{ref_ext} / (PREDIV + 1) 40$

Field	Description															
20–21 DEPTH[0:1]	<p>Controls the frequency modulation depth and enables the frequency modulation. When programmed to a value other than 0x0, the frequency modulation is automatically enabled. The programmable frequency deviations from the system frequency are shown below. If the depth is changed to a value other than 0x0, the calibration sequence is reinitialized.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>DEPTH[1]</th> <th>DEPTH[0]</th> <th>Modulation Depth (% of Fsys)</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> </tr> <tr> <td>0</td> <td>1</td> <td>1.0 ± 0.2</td> </tr> <tr> <td>1</td> <td>0</td> <td>2.0 ± 0.2</td> </tr> <tr> <td>1</td> <td>1</td> <td>Reserved</td> </tr> </tbody> </table> <p>Note: To avoid unintentional interrupt requests, clear LOLIRQ before changing DEPTH.</p>	DEPTH[1]	DEPTH[0]	Modulation Depth (% of Fsys)	0	0	0	0	1	1.0 ± 0.2	1	0	2.0 ± 0.2	1	1	Reserved
DEPTH[1]	DEPTH[0]	Modulation Depth (% of Fsys)														
0	0	0														
0	1	1.0 ± 0.2														
1	0	2.0 ± 0.2														
1	1	Reserved														
22–31 EXP[0:9]	<p>Expected difference value. Holds the expected value of the difference of the reference and the feedback counters. Refer to Section 11.4.3.3, “FM Calibration Routine” to determine the value of these bits. This field is written by the application before entering calibration mode.</p>															

11.3.1.2 Synthesizer Status Register (FMPLL_SYNSR)

The synthesizer status register (FMPLL_SYNSR) is a 32-bit register. Only the LOLF and LOCF flag bits are writable in this register. Writes to bits other than the LOLF and LOCF have no effect.

Address: Base + 0x0004

Access: User R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	— ¹	— ¹	— ¹	— ¹	— ²	0	0	0

¹ Reset state determined during reset configuration. (Refer to [Section 11.1.4, “FMPLL Modes of Operation,”](#) for more information.)

² Reset state determined during reset.

Note: “w1c” signifies that this bit is cleared by writing a 1 to it.

Figure 11-9. Synthesizer Status Register (FMPLL_SYNSR)

Table 11-5. FMPLL_SYNCR Field Descriptions

Field	Description
0–21	Reserved.
22 LOLF	<p>Loss-of-lock flag. Provides the interrupt request flag. This is a write 1 to clear (w1c) bit; to clear the flag, the user must write a 1 to the bit. Writing 0 has no effect. This flag is not set and an interrupt is not requested, if the loss-of-lock condition was caused by:</p> <ul style="list-style-type: none"> • a system reset • a write to the FMPLL_SYNCR which modifies the MFD bits • enabling frequency modulation <p>If the flag is set due to a system failure, writing the MFD bits or enabling FM does not clear the flag. Asserting reset clears the flag. This flag bit is sticky; if lock is reacquired, the bit remains set until either a write of 1 or reset is asserted.</p> <p>0 Interrupt service not requested 1 Interrupt service requested</p> <p>Note: Upon a loss-of-lock that is not generated by:</p> <ul style="list-style-type: none"> • a system reset • a write to the FMPLL_SYNCR that modifies the MFD or PREDIV bits • enabling of frequency modulation <p>the LOLF is set <i>only if</i> LOLIRQ is set. If the FMPLL reacquires lock and any of the previous conditions in the bulleted list occurs, the LOLF is set again. To avoid generating an unintentional interrupt, clear LOLIRQ before changing MFD or PREDIV, or before enabling FM after a previous interrupt and relock occurred.</p>
23 LOC	<p>Loss-of-clock status. Indicates whether a loss-of-clock condition is present when operating in crystal reference, external reference, or dual-controller mode. If LOC = 0, the system clocks are operating normally. If LOC = 1, the system clocks have failed due to a reference failure or a FMPLL failure. If the read of the LOC bit and the loss-of-clock condition occur simultaneously, the bit does not reflect the current loss of clock condition. If a loss-of-clock condition occurs which sets this bit and the clocks later return to normal, this bit is cleared.</p> <p>A loss of clock condition can only be detected if LOCEN = 1. LOC is always 0 in bypass mode.</p> <p>0 Clocks are operating normally 1 Clocks are not operating normally.</p>
24 MODE	<p>Clock mode. Determined at reset, this bit indicates which clock mode the system is utilizing. Refer to Chapter 4, “Reset,” for details on how to configure the system clock mode during reset.</p> <p>0 PLL bypass mode. 1 PLL clock mode.</p>
25 PLLSEL	<p>PLL mode select. Determined at reset, this bit indicates in which mode the FMPLL operates. This bit is cleared in dual-controller and bypass mode. Refer to Chapter 4, “Reset,” for details on how to configure the system clock mode during reset. Refer to Table 11-1 for more information.</p> <p>0 Dual-controller mode. 1 Crystal reference or external reference mode.</p>

Table 11-5. FMPLL_SYNSR Field Descriptions (continued)

Field	Description
26 PLLREF	<p>PLL clock reference source. Determined at reset, this bit indicates whether the PLL reference source is an external clock or a crystal reference. This bit is cleared in dual controller mode and bypass mode. Refer to Chapter 4, “Reset,” for details on how to configure the system clock mode during reset.</p> <p>0 External clock reference chosen. 1 Crystal clock reference chosen.</p>
27 LOCKS	<p>Sticky FMPLL lock status bit. A sticky indication of FMPLL lock status. LOCKS is set by the lock detect circuitry when the FMPLL acquires lock after one of the following:</p> <ul style="list-style-type: none"> • System reset • Write to the FMPLL_SYNSR that modifies the MFD and PREDIV bits • Enable frequency modulation <p>Whenever the FMPLL loses lock, LOCKS is cleared. LOCKS remains cleared even after the FMPLL relocks, until one of the three previously-stated conditions occurs. Furthermore, if the LOCKS bit is read when the FMPLL simultaneously loses lock, the bit does not reflect the current loss of lock condition.</p> <p>If operating in bypass mode, LOCKS remains cleared after reset. In crystal reference, external reference, and dual-controller mode, LOCKS is set after reset.</p> <p>0 PLL has lost lock since last system reset, a write to FMPLL_SYNSR to modify the MFD and PREDIV bit fields, or frequency modulation enabled. 1 PLL has not lost lock since last system reset, a write to FMPLL_SYNSR to modify the MFD and PREDIV bit fields, or frequency modulation enabled.</p>
28 LOCK	<p>PLL lock status bit. Indicates whether the FMPLL has acquired lock. If the LOCK bit is read when the FMPLL simultaneously loses lock or acquires lock, the bit does not reflect the current condition of the FMPLL.</p> <p>If operating in bypass mode, LOCK remains cleared after reset. Refer to the frequency as defined in the <i>MPC5565 Microcontroller Data Sheet</i> for the lock/unlock range.</p> <p>0 PLL is unlocked. 1 PLL is locked.</p>
29 LOCF	<p>Loss-of-clock flag. This bit provides the interrupt request flag. This is a write 1 to clear (w1c) bit; to clear the flag, the user must write a 1 to the bit. Writing 0 has no effect. Asserting reset clears the flag. This flag is sticky in the sense that if clocks return to normal after the flag has been set, the bit remains set until cleared by either writing 1 or asserting reset.</p> <p>0 Interrupt service not requested 1 Interrupt service requested</p>

Table 11-5. FMPLL_SYNSR Field Descriptions (continued)

Field	Description
30 CALDONE	Calibration complete. Indicates whether the calibration sequence has been completed since the last time modulation was enabled. If CALDONE = 0 then the calibration sequence is either in progress or modulation is disabled. If CALDONE = 1 then the calibration sequence has been completed, and frequency modulation is operating. 0 Calibration not complete. 1 Calibration complete. Note: FM relocking does not start until calibration is complete.
31 CALPASS	Calibration passed. Indicates whether the calibration routine was successful. If CALPASS = 1 and CALDONE = 1 then the routine was successful. If CALPASS = 0 and CALDONE = 1, then the routine was unsuccessful. When the calibration routine is initiated the CALPASS is asserted. CALPASS remains asserted until either modulation is disabled by clearing the DEPTH bits in the FMPLL_SYNSR or a failure occurs within the FMPLL calibration sequence. 0 Calibration unsuccessful. 1 Calibration successful. If calibration is unsuccessful, then actual depth is not guaranteed to match the desired depth.

11.4 Functional Description

This section explains clock architecture, clock operation, and clock configuration.

11.4.1 Clock Architecture

This section describes the clocks and clock architecture in the MCU.

11.4.1.1 Overview

The system clocks are generated from one of four FMPLL modes: crystal reference mode, external reference mode, dual-controller (1:1) mode, and bypass mode. Refer to [Section 11.1, “Introduction”](#) for information on the different clocking modes available in the FMPLL.

The peripheral IP modules have been designed to allow software to gate the clocks to the non-memory-mapped logic of the modules.

The MCU has three clock output pins that are driven by programmable clock dividers. The clock dividers divide the system clock down by even integer values. The three clock output pins are the following:

- CLKOUT – External address/data bus clock
- MCKO – Nexus auxiliary port clock
- ENGCLK – Engineering clock

The MCU has been designed so that the oscillator clock can be selected as the clock source for the CAN interface in the FlexCAN blocks resulting in very low jitter performance.

[Figure 11-1](#) shows a block diagram of the FMPLL and the system clock architecture.

11.4.1.2 Software Controlled Power Management/Clock Gating

Some of the IP modules on this device support software controlled power management/clock gating whereby the application software can disable the non-memory-mapped portions of the modules by writing to module disable (MDIS) bits in registers within the modules. The memory-mapped portions of the modules are clocked by the system clock when they are being accessed. The NPC can be configured to disable the MCKO signal when there are no Nexus messages pending. The H7FA Flash array can be disabled by writing to a bit in the Flash register map.

The modules that implemented software controlled power management/clock gating are listed in [Table 11-6](#) along with the registers and bits that disable each module. The software controlled clocks are enabled when the MCU comes out of reset.

Table 11-6. Software Controlled Power Management/Clock Gating Support

Module Name	Register Name	Bit Names
DSPI B	DSPI_B_MCR	MDIS
DSPI C	DSPI_C_MCR	MDIS
DSPI D	DSPI_D_MCR	MDIS
EBI	EBI_MCR	MDIS
eTPU engine A	ETPUECR_1	MDIS
FlexCAN A	FLEXCAN_A_MCR	MDIS
FlexCAN B	FLEXCAN_B_MCR	MDIS
FlexCAN C	FLEXCAN_C_MCR	MDIS
eMIOS	EMIOS_MCR	MDIS
eSCI A	ESCIA_CR2	MDIS
eSCI B	ESCIB_CR2	MDIS
NPC	NPC_PCR	MCKO_EN, MCKO_GT ¹
Flash array	FLASH_MCR	STOP ²

¹ Refer to [Chapter 24, “Nexus Development Interface.”](#)

² Refer to [Chapter 13, “Flash Memory.”](#)

11.4.1.3 Clock Dividers

Each of the CLKOUT, MCKO, and ENGCLK dividers provides a nominal 50% duty cycle clock to an output pin. There is no guaranteed phase relationship between CLKOUT, MCKO, and ENGCLK. ENGCLK is not synchronized to any I/O pins.

11.4.1.3.1 External Bus Clock (CLKOUT)

The external bus clock (CLKOUT) divider can be programmed to divide the system clock by two or four based on the settings of the EBDF bit field in the SIU external clock control register (SIU_ECCR). The reset value of the EBDF selects a CLKOUT frequency of one half of the system clock frequency. The EBI

supports gating of the CLKOUT signal when there are no external bus accesses in progress. Refer to the [Chapter 6, “System Integration Unit \(SIU\)”](#) for more information on CLKOUT.

The hold-time for the external bus pins can be changed by writing to the external bus tap select (EBTS) bit in the SIU_ECCR. Refer to [Chapter 6, “System Integration Unit \(SIU\)”](#) for more information.

11.4.1.3.2 Nexus Message Clock (MCKO)

The Nexus message clock (MCKO) divider can be programmed to divide the system clock by two, four or eight based on the MCKO_DIV bit field in the port configuration register (PCR) in the Nexus port controller (NPC). The reset value of the MCKO_DIV selects an MCKO clock frequency one half of the system clock frequency. The MCKO divider is configured by writing to the NPC through the JTAG port. Refer to [Chapter 24, “Nexus Development Interface”](#) for more information.

11.4.1.3.3 Engineering Clock (ENGCLK)

The engineering clock (ENGCLK) divider can be programmed to divide the system clock by factors from 2 to 126 in increments of two. The ENGDIV bit field in the SIU_ECCR determines the divide factor. The reset value of ENGDIV selects an ENGCLK frequency of system clock divided by 32.

11.4.1.3.4 FlexCAN_x Clock Domains

The FlexCAN modules have two distinct software controlled clock domains. One of the clock domains is always derived from the system clock. This clock domain includes the message buffer logic. The source for the second clock domain can be either the system clock or a direct feed from the oscillator pin EXTAL_EXTCLK. The logic in the second clock domain controls the CAN interface pins. The CLK_SRC bit in the FlexCAN CTRL register selects between the system clock and the oscillator clock as the clock source for the second domain. Selecting the oscillator as the clock source ensures very low jitter on the CAN bus. System software can gate both clocks by writing to the MDIS bit in the FlexCAN MCR register. [Figure 11-1](#) shows the two clock domains in the FlexCAN modules.

Refer to [Chapter 21, “FlexCAN2 Controller Area Network”](#) for more information on the FlexCAN modules.

11.4.2 Clock Operation

11.4.2.1 Input Clock Frequency

The FMPLL is designed to operate over an input clock frequency range as determined by the operating mode. The operating ranges for each mode are given in [Table 11-7](#).

Table 11-7. Input Clock Frequency

Mode	Symbol	Input Frequency Range
Crystal reference External reference	$F_{ref_crystal}$ F_{ref_ext}	8–20 MHz
Bypass	F_{extal}	0–132 MHz
Dual-controller (1:1)	$F_{ref_1:1}$	25–66 MHz

11.4.2.2 Reduced Frequency Divider (RFD)

The RFD can be used for reducing the FMPLL system clock frequency. To protect the system from frequency overshoot during the PLL lock detect phase, the RFD must be programmed to be greater than or equal to 1 when changing MFD or PREDIV or when enabling frequency modulation.

11.4.2.3 Programmable Frequency Modulation

The FMPLL provides for frequency modulation of the system clock. The modulation is applied as a triangular waveform with modulation depth and rate controlled by fields in the FMPLL_SYNCR. The modulation depth can be set to +/-1% or +/-2% of the system frequency. The modulation rate is dependent on the reference clock frequency.

Complete details for configuring the programmable frequency modulation is given in [Section 11.4.3.2, “Programming System Clock Frequency with Frequency Modulation.”](#)

11.4.2.4 FMPLL Lock Detection

A pair of counters monitor the reference and feedback clocks to determine when the system has acquired frequency lock. After the FMPLL has locked, the counters continue to monitor the reference and feedback clocks and reports if/when the FMPLL has lost lock. The FMPLL_SYNCR provides the flexibility to select whether to generate an interrupt, assert system reset, or do nothing in the event that the FMPLL loses lock. Refer to [Section 11.3.1.1, “Synthesizer Control Register \(FMPLL_SYNCR\)](#) for details.

When the frequency modulation is enabled, the loss of lock continues to function as described but with the lock and loss of lock criteria reduced to ensure that false loss of lock conditions are not detected.

In bypass mode, the FMPLL cannot lock since the FMPLL is disabled.

11.4.2.5 FMPLL Loss-of-Lock Conditions

After the FMPLL acquires lock after reset, the FMPLL_SYNSR[LOCK] and FMPLL_SYNSR[LOCKS] status bits are set. If the MFD is changed or if an unexpected loss of lock condition occurs, the LOCK and LOCKS status bits are negated. While the FMPLL is in an unlocked condition, the system clocks continue to be sourced from the FMPLL as the FMPLL attempts to re-lock. Consequently, during the re-locking

process, the system clock frequency is not well defined and can exceed the maximum system frequency thereby violating the system clock timing specifications (when changing MFD and PREDIV, this is avoided by following the procedure detailed in [Section 11.4.3, “Clock Configuration”](#)). Because this condition can arise during unexpected loss of lock events, it is recommended to use the loss of lock reset functionality, Refer to [Section 11.4.2.5.1, “FMPLL Loss-of-Lock Reset,”](#) below. However, LOLRE must be cleared while changing the MFD otherwise a reset occurs.

After the FMPLL has relocked, the LOCK bit is set. The LOCKS bit remains cleared if the loss of lock was unexpected. The LOCKS bit is set to 1 when the loss of lock was caused by changing the MFD.

11.4.2.5.1 FMPLL Loss-of-Lock Reset

The FMPLL provides the ability to assert reset when a loss of lock condition occurs by programming the FMPLL_SYNCR[LOLRE] bit. Reset is asserted if LOLRE is set and loss of lock occurs. Because the FMPLL_SYNSR[LOCK] and FMPLL_SYNSR[LOCKS] bits are reinitialized after reset, the system reset status register (SIU_RSR) must be read to determine that a loss of lock condition occurred.

To exit reset, the reference must be present and the FMPLL must acquire lock. In bypass mode, the FMPLL cannot lock. Therefore a loss of lock condition cannot occur, and LOLRE has no effect.

11.4.2.5.2 FMPLL Loss-of-Lock Interrupt Request

The FMPLL provides the ability to request an interrupt when a loss of lock condition occurs by programming the FMPLL_SYNCR[LOLIRQ] bit. An interrupt is requested by the FMPLL if LOLIRQ is set and loss of lock occurs.

In bypass mode, the FMPLL cannot lock. Therefore a loss of lock condition cannot occur, and the LOLIRQ bit has no effect.

11.4.2.6 Loss-of-Clock Detection

The FMPLL continuously monitors the reference and feedback clocks. In the event either of the clocks fall below a threshold frequency, the system reports a loss of clock condition. The user can enable a feature to have the FMPLL switch the system clocks to a backup clock in the event of such a failure. Additionally, the user can select to have the system enter reset, assert an interrupt request, or do nothing if/when the FMPLL reports this condition.

11.4.2.6.1 Alternate/Backup Clock Selection

If the user enables loss of clock by setting FMPLL.SYNCR[LOCEN] = 1, then the FMPLL transitions system clocks to a backup clock source in the event of a clock failure as per [Table 11-8](#).

If loss of clock is enabled and the reference clock is the source of the failure, the FMPLL enters self-clock mode (SCM). The exact frequency during self-clock mode operation is indeterminate due to process, voltage, and temperature variation but is guaranteed to be below the maximum system frequency. If the FMPLL clocks have failed, the FMPLL transitions the system clock source to the reference clock.

The FMPLL remains in SCM until the next reset. Note that when the FMPLL is operated in SCM, writes to FMPLL_SYNCNCR[RFD] have no effect on clock frequency. The SCM system frequency stated in the device *Data Sheet* assumes that the RFD has been programmed to 0x0.

If loss of clock is enabled and the loss-of-clock is due to a FMPLL failure (for example, loss of feedback clock), the FMPLL reference becomes the system clock’s source until the next reset, even if the FMPLL regains itself and re-locks.

Table 11-8. Loss of Clock Summary

Clock Mode	System Clock Source before Failure	REFERENCE FAILURE Alternate Clock Selected by LOC Circuitry until Reset	PLL FAILURE Alternate Clock Selected by LOC Circuitry until Reset
Crystal Reference External Reference	PLL	PLL self-clocked mode	PLL reference
Bypass	External clock(s)	None	N/A

A special loss of clock condition occurs when both the reference and the FMPLL fail. The failures can be simultaneous or the FMPLL can fail first. In either case, the reference clock failure takes priority and the FMPLL attempts to operate in SCM. If successful, the FMPLL remains in SCM until the next reset. During SCM, modulation is always disabled. If the FMPLL cannot operate in SCM, the system remains static until the next reset. Both the reference and the FMPLL must be functioning properly to exit reset.

11.4.2.6.2 Loss-of-Clock Reset

When a loss of clock condition is recognized, reset is asserted if the FMPLL_SYNCNCR[LOCRE] bit is set. The LOCF and LOC bits in FMPLL_SYNSR are cleared after reset, therefore, the SIU_RSR must be read to determine that a loss of clock condition occurred. LOCRE has no effect in bypass mode.

To exit reset in FMPLLmode, the reference must be present and the FMPLL must acquire lock.

11.4.2.6.3 Loss-of-Clock Interrupt Request

When a loss of clock condition is recognized, the FMPLL requests an interrupt if the FMPLL_SYNCNCR[LOCIRQ] bit is set. The LOCIRQ bit has no effect in bypass mode or if FMPLL_SYNCNCR[LOCEN] = 0.

11.4.3 Clock Configuration

In crystal reference and external reference clock mode, the default system frequency is determined by the MFD, RFD, and PREDIV reset values. Refer to [Section 11.3.1.1, “Synthesizer Control Register \(FMPLL_SYNCNCR\).”](#) The frequency multiplier is determined by the RFD, PREDIV, and multiplication frequency divisor (MFD) bits in FMPLL_SYNCNCR.

[Table 11-9](#) shows the clock-out to clock-in frequency relationships for the possible clock modes.

Table 11-9. Clock-out vs. Clock-in Relationships

Clock Mode	PLL Option
Crystal Reference Mode	$F_{\text{sys}} = F_{\text{ref_crystal}} \times \frac{(MFD + 4)}{((PREDIV + 1) \times 2^{RFD})}$
External Reference Mode	$F_{\text{sys}} = F_{\text{ref_ext}} \times \frac{(MFD + 4)}{((PREDIV + 1) \times 2^{RFD})}$
Dual Controller (1:1) Mode	$F_{\text{sys}} = 2F_{\text{ref_1:1}}$
Bypass Mode	$F_{\text{sys}} = F_{\text{ref_ext}}$

NOTES:

F_{sys} = system frequency

F_{prediv} = clock frequency after PREDIV.

$F_{\text{ref_crystal}}$ and $F_{\text{ref_ext}}$ = clock frequencies at the EXTAL_EXTCLK signal. (Refer to [Figure 11-1](#)).

MFD ranges from 0 to 31.

RFD ranges from 0 to 7.

PREDIV normal reset value is 0. Caution: Programming a PREDIV value such that the ICO operates outside its specified range causes unpredictable results and the FMPLL does not lock. Refer to the device *Data Sheet* for details on the ICO range.

When programming the FMPLL, do not violate the maximum system clocks frequency, or maximum and minimum ICO frequency specifications. For determining the MFD value, use a value of zero for the RFD (translates to divide-by-one). This ensures that the FMPLL does not try to synthesize a frequency out of its range. Refer to the device *Data Sheet* for more information.

11.4.3.1 Programming System Clock Frequency Without Frequency Modulation

The following steps are required to accommodate the frequency overshoot that can occur when the PREDIV or MFD bits are changed. If frequency modulation is going to be enabled, the maximum allowable frequency must be reduced by the programmed ΔF_m .

NOTE

Following these steps produces immediate changes in supply current, therefore make sure the power supply is decoupled with low ESR capacitors.

The following steps program the clock frequency without frequency modulation:

1. Determine the value for the PREDIV, MFD, and RFD fields in the synthesizer control register (FMPLL_SYNCR). Remember to include the ΔF_m if frequency modulation is enabled. The amount of jitter in the system clocks can be minimized by selecting the maximum MFD factor that can be paired with an RFD factor to provide the desired frequency. The maximum MFD value that can be used is determined by the ICO range. Refer to the *Data Sheet* for the maximum frequency of the ICO.

2. Change the following in FMPLL_SYNCR:
 - a) Make sure frequency modulation is disabled (FMPLL_SYNCR[DEPTH] = 00). A change to PREDIV, MFD, or RATE while modulation is enabled invalidates the previous calibration results.
 - b) Clear FMPLL_SYNCR[LOLRE]. If this bit is set, the MCU goes into reset when MFD is written.
 - c) Initialize the FMPLL for less than the desired final system frequency (done in one single write to FMPLL_SYNCR):
 - Disable LOLIRQ.
 - Write FMPLL_SYNCR[PREDIV] to a desired final value.
 - Write FMPLL_SYNCR[MFD] to a desired final value.
 - Write the RFD control field value to a desired final RFD value + one.
3. Wait for the FMPLL to lock by monitoring the FMPLL_SYNSR[LOCK] bit. Refer to [Section 11.3.1.1, “Synthesizer Control Register \(FMPLL_SYNCR\),”](#) for memory synchronization between changing FMPLL_SYNCR[MFD] and monitoring the lock status.
4. Initialize the FMPLL to the desired final system frequency by changing FMPLL_SYNCR[RFD]. The FMPLL does not need to re-lock if only the RFD changes, and the RFD must be set to greater than one to protect from overshoot.
5. Reenable LOLIRQ.

NOTE

When using crystal reference mode or external reference mode, do not set the PREDIV value to any value that causes the phase/frequency detector to go below 4 MHz. That is, the crystal or external clock frequency divided by the PREDIV value must be in the range of 4–20 MHz.

NOTE

This first register write causes the FMPLL to switch to an initial system frequency which is less than the final one. Keeping the change of frequency to a lower initial value helps minimize the current surge to the external power supply caused by the change in frequency. The last step changes the RFD to get the desired final frequency.

NOTE

Changing the MFD or PREDIV values causes the FMPLL to perform a search for the lock frequency that results in the system clock frequency changing rapidly across the complete frequency range. All MCU peripherals, including the external bus are subjected to this frequency sweep. Operation of timers and serial communications during this search sequence produces unpredictable results.

11.4.3.2 Programming System Clock Frequency with Frequency Modulation

In crystal reference and external reference clock modes, the default mode is without frequency modulation enabled. When frequency modulation is enabled, however, three parameters must be set to generate the desired level of modulation: the RATE, DEPTH, and EXP bit fields of the FMPLL_SYNCR. RATE and DEPTH determine the modulation rate and the modulation depth. The EXP field controls the FM calibration routine. Section 11.4.3.3, “FM Calibration Routine,” shows how to obtain the values to be programmed for EXP. Figure 11-10 illustrates the effects of the parameters and the modulation waveform built into the modulation hardware. The modulation waveform is always a triangle wave and its shape is not programmable.

The modulation rates given are specific to a reference frequency of 8 MHz. F_{prediv} is the frequency after the predivider.

$$F_{\text{mod}} = F_{\text{ref_crystal}} \text{ or } F_{\text{ref_ext}} / (\text{PREDIV} + 1) \times Q$$

where:

$Q = 40$ or 80 . This gives modulation rates of 200 kHz and 100 kHz, respectively.

NOTE

If a 40 MHz input is used, PLLCFG2 must equal 1. After exiting reset, PREDIV and any subsequent writes must be ≥ 1 .

NOTE

The following relationship between F_{mod} and modulation rates must be maintained:

$$100 \text{ KHz} \leq F_{\text{mod}} \leq 250 \text{ KHz}$$

Therefore, the use of a non 8 MHz reference results in scaled modulation rates.

Here are the steps to program the clock frequency with frequency modulation. These steps ensure proper operation of the calibration routine and prevent frequency overshoot from the sequence:

1. Change the following in FMPLL_SYNCR:
 - a) Make sure frequency modulation is disabled (FMPLL_SYNCR[DEPTH] = 00). A change to PREDIV, MFD, or RATE while modulation is enabled invalidates the previous calibration results.
 - b) Clear FMPLL_SYNCR[LOLRE]. If this bit is set, the MCU goes into reset when MFD is written.
 - c) Initialize the FMPLL for less than the desired final frequency:
 - Disable LOLIRQ.
 - Write FMPLL_SYNCR[PREDIV] to the desired final value.
 - Write FMPLL_SYNCR[MFD] to the desired final value.
 - Write FMPLL_SYNCR[EXP] to the desired final value.
 - Write FMPLL_SYNCR[RATE] to the desired final value.

- Write the RFD control field to 1 + the desired final RFD value (RFD must be greater than one to protect from overshoot).
- 2. Wait for the FMPLL to lock by monitoring the FMPLL_SYNSR[LOCK] bit. Refer to [Section 11.3.1.1, “Synthesizer Control Register \(FMPLL_SYNCR\),”](#) for memory synchronization between changing FMPLL_SYNCR[MFD] and monitoring the lock status.
- 3. If using the frequency modulation feature, then:
 - a) Enable FM by setting FMPLL_SYNCR[DEPTH] = 1 or 2.
 - b) Also set FMPLL_SYNCR[RATE] if not done previously in step 2.
- 4. Calibration starts. After calibration is done, then the FMPLL re-locks. Wait for the FMPLL to re-lock by monitoring the FMPLL_SYNSR[LOCK] bit.
- 5. Verify FM calibration completed and was successful by testing the FMPLL_SYNSR[CALDONE] and FMPLL_SYNSR[CALPASS] bitfields.
- 6. If FM calibration did not complete or was not successful, attempt again by going back to step 1.
- 7. Initialize the FMPLL to the desired final system frequency by changing FMPLL_SYNCR[RFD]. Note that the FMPLL does not need to re-lock when only changing the RFD.
- 8. Re-enable LOLIRQ.

NOTE

This first register write causes the FMPLL to switch to an initial frequency which is less than the final one. Keeping the change of frequency to a lower initial value helps minimize the current surge to the external power supply caused by change of frequency. The last step changes the RFD to get the final frequency.

NOTE

Changing the MFD or PREDIV values causes the FMPLL to perform a search for the lock frequency that results in the system clock frequency changing rapidly across the complete frequency range. All MCU peripherals, including the external bus, are subjected to this frequency sweep. Operation of timers and serial communications during this search sequence produces unpredictable results.

Note that the frequency modulation system is dependent upon several factors: the accuracies of the V_{DDSYN}/V_{SSSYN} voltage, of the crystal oscillator frequency, and of the manufacturing variation.

For example, if a 5% accurate supply voltage is used, then a 5% modulation depth error results. If the crystal oscillator frequency is skewed from 8 MHz, the resulting modulation frequency is proportionally skewed. Finally, the error due to the manufacturing and environment variation alone can cause the frequency modulation depth error to be greater than 20%.

Figure 11-10. Frequency Modulation Waveform

11.4.3.3 FM Calibration Routine

Upon enabling frequency modulation, a new calibration routine is performed. This routine tunes a reference current into the modulation D/A so that the modulation depth (F_{\max} and F_{\min}) remains within specification.

Entering the FM calibration mode requires the user to program SYNCR[EXP]. The EXP is the expected value of the difference between the reference and feedback counters used in the calibration of the FM equation:

$$\text{EXP} = \frac{((\text{MFD} + 4) \times \text{M} \times \text{P})}{100}$$

For example, if 80 MHz is the desired final frequency and an 8 MHz crystal is used, the final values of $\text{MFD} = 6$ and $\text{RFD} = 0$ produces the desired 80 MHz. For a desired frequency modulation with a 1% depth, then EXP is calculated using $\text{P} = 1$, $\text{MFD} = 6$ and $\text{M} = 480$. Refer to [Table 11-10](#) for a complete list of values to be used for the variable (M) based on MFD setting. To obtain a percent modulation (P) of 1%, the EXP field would have to be set at: $\text{EXP} = ((6 + 4) \times 640 \times 1) \div 100 = 48$

Rounding this value to the closest integer yields 48, which is entered into the EXP field for this example.

Table 11-10. Multiplied Factor Dividers with M Values

MFD	M
0–2	960
3–5	640
6–8	480
9–14	320
15–20	240
21–31	160

This routine corrects for process variations, but because temperature can change after calibration is performed, the variation caused by temperature drift remains. This frequency modulation calibration system is also voltage dependent, so if the supply changes after the sequence occurs, errors incurred are not corrected. The calibration system reuses the two counters in the lock detect circuit, and the reference and feedback counters. The reference counter remains clocked by the reference clock, but the feedback counter is clocked by the ICO clock.

When the calibration routine is initiated by writing to the DEPTH bits, the CALPASS status bit is immediately set and the CALDONE status bit is immediately cleared.

When calibration is induced, the ICO is given time to settle. Then both the feedback and reference counters start counting. Full ICO clock cycles are counted by the feedback counter during this time to give the initial center frequency count. When the reference counter has counted to the programmed number of reference count cycles, the input to the feedback counter is disabled and the result is placed in the COUNT0 register. The calibration system then enables modulation at programmed ΔF_m . The ICO is given time to settle. Both counters are reset and restarted. The feedback counter begins to count full ICO clock cycles again to obtain the delta-frequency count. When the reference counter has counted to the new programmed number of reference count cycles, the feedback counter is stopped again.

The delta-frequency count minus the center frequency count (COUNT0) results in a delta count proportional to the reference current into the modulation D/A. That delta count is subtracted from the expected value given in the EXP field of the FMPLL_SYNCR resulting in an error count. The sign of this error count determines the direction taken by the calibration D/A to update the calibration current. After obtaining the error count for the present iteration, both counters are cleared. The stored count of COUNT0 is preserved while a new feedback count is obtained, and the process to determine the error count is repeated. The calibration system repeats this process eight times, once for each bit of the calibration D/A.

After the last decision is made, the CALDONE bit of the SYNSR is written to a one. If an error occurs during the calibration routine, then CALPASS is immediately written to a zero. If the routine completed successfully then CALPASS remains a one.

Figure 11-11 shows a block diagram of the calibration circuitry and its associated registers. Figure 11-12 shows a flow chart showing the steps taken by the calibration circuit.

Chapter 12

External Bus Interface (EBI)

12.1 Introduction

This chapter describes the external bus interface (EBI), which handles the transfer of information between the internal buses and the memories or peripherals in the external address space and enables an external master to access internal address space. For an overview of how the EBI used in the MPC5500 differs from the EBI used in MPC500 devices, refer to [Section 12.5.6, “Summary of Differences from MPC5xx.”](#)

12.1.1 Block Diagram

Figure 12-1 is a block diagram of the EBI. The signals shown are external pins to the MCU.

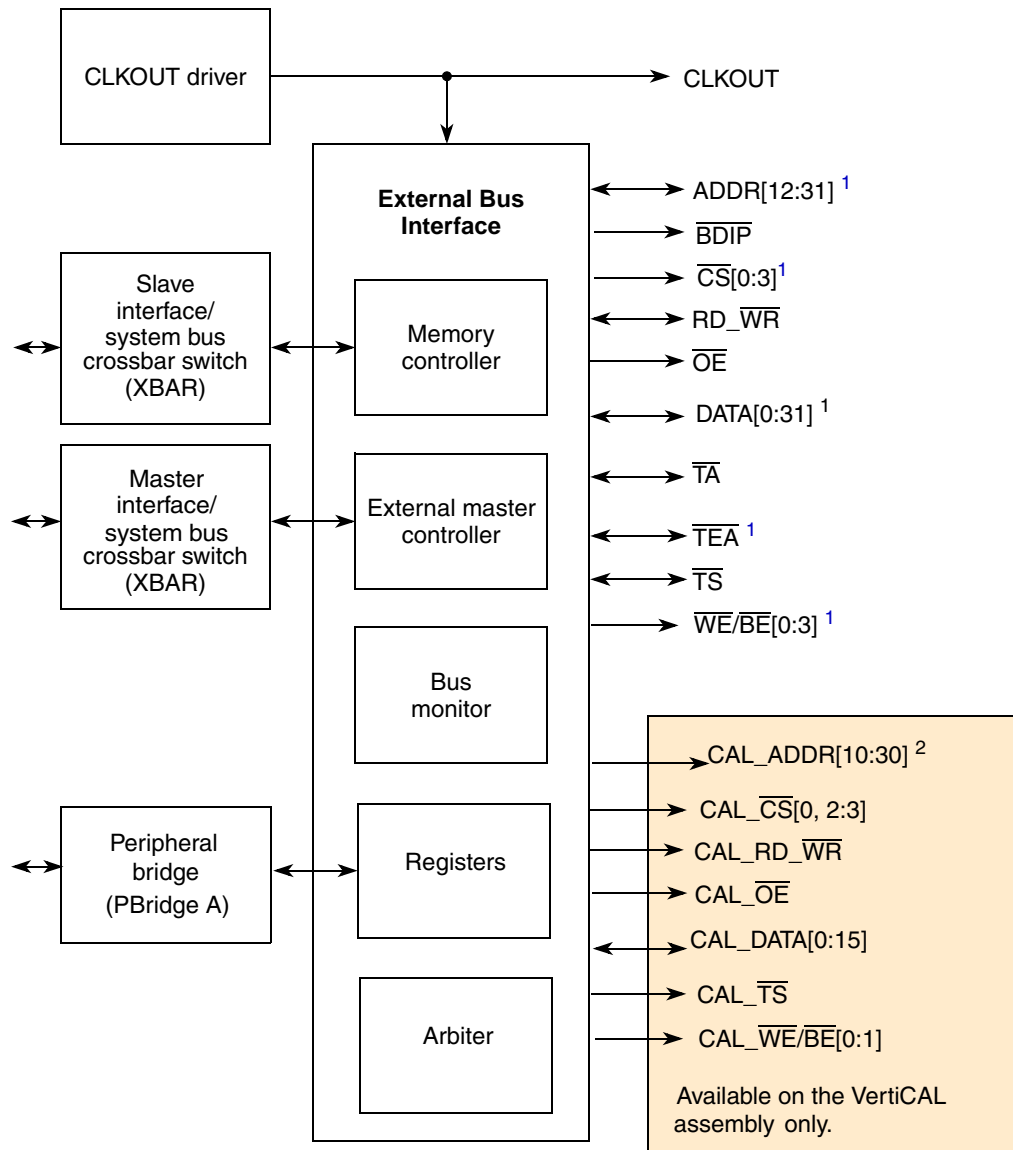

NOTE

Refer to in the Signals chapter, as not all signals are implemented in all device packages. The last two columns in for a list of available signals on the 324 package and the VertiCal assembly. The VertiCal assembly has ball connections for all the *available* signals on the device.

The 324 package has a limited number of balls which affects the following EBI and calibration signals:

Table 12-1. MPC5565 324 Package Limitations

Features	MPC5565 Design	324 Package
Maximum 24-bit EBI address bus	ADDR[8:31]_GPIO[4:27]; ADDR[8:11] are muxed as alternate signals with the chip select signals $\overline{CS}[0:3]_{_}ADDR[8:11]_{_}GPIO[0:3]$. ADDR[8:11] is also muxed with GPIO[4:7], providing four chip selects <i>and</i> 24-bit address bits.	ADDR[8:11]_GPIO[4:7] no balls available. Use $\overline{CS}[0:3]_{_}ADDR[8:11]_{_}GPIO[0:3]$ to choose between using chip select signals <i>or</i> maximizing the number of output address signals ADDR[8:31]_GPIO[0:3, 8:31] for a 24-bit EBI address bus.
Maximum 32-bits wide EBI data bus	DATA[0:31]_GPIO[28:59]	16 balls available for a 16-bit wide DATA[0:15]_GPIO[28:43]. There are no balls available for DATA[16:31]_GPIO[44:59].
Four EBI write enable/byte enable	$\overline{WE}/\overline{BE}[0:3]$	Two balls available ($\overline{WE}/\overline{BE}[0:1]$)
EBI transfer error acknowledge	$\overline{TEA}_{_}GPIO[71]$	No ball available
EBI bus busy	\overline{BB} signal not available	$\overline{BB}_{_}GPIO[72]$ no ball available
EBI bus grant	\overline{BG} signal not available	$\overline{BG}_{_}GPIO[73]$ no ball available
Calibration bus	Calibration bus is separate from the EBI but uses the EBI controller. Refer to for the calibration bus signals.	No balls available. These signals are only available in the VertiCal assembly.

¹ Although the MPC5565 is designed to support a 32-bit EBI, not all pins are available on the 324 package. Refer to [Table 12-1](#) for a description of the differences between the device design and package pinouts.

² The MPC5565 calibration bus and calibration signals are only available on the VertiCAL assembly.

Figure 12-1. MPC5565 EBI Connections

12.1.2 Overview

The EBI includes a memory controller that generates interface signals to support a variety of external memories. This includes single data rate (SDR) burst mode flash, external SRAM, and asynchronous memories. It supports up to four regions (via chip selects), each with its own programmed attributes.

12.1.3 Features

The device includes design for the following features:

- 1.8–3.3 V I/O
- Address bus is 32-bit with transfer size indication
- 32-bit internal address bus with transfer size indication

Table 12-2 shows the address bus packages supported:

Table 12-2. Address Bus Sizes in MPC5565

	324 BGA	
EBI Address Bus Size	24 bits ¹	20 bits ²
Calibration Address Bus Size	19, 20, or 21 bits ³	

¹ 24 bits available: ADDR[12:31] is the default pin set, then CS[0:3]_ADDR[8:11]_GPIO [0:3] must be configured by PCR to ADDR[8:11] to attain the 24-bit size.

² 20 bits is the default EBI size for the 324 package (ADDR[12:31]).

³ The calibration feature is only available using the VertiCal assembly. The default calibration address bus is 19 bits muxed with CAL_ADDR[12:30]. However, it can be configured to use CAL_ADDR[10:11] of the muxed signals CAL_CS[2:3]_CAL_ADDR[10:11] to increase the calibration bus size to the maximum allowable width on this device of 21 bits.

Table 12-3 shows the data bus packages supported:

- 32-bit data bus available for both external memory accesses and transactions involving an external master.

Table 12-3. Data Bus Size in MPC5565

Bus	324 BGA
EBI data bus size	32 bits ¹
Calibration data bus size	16 bits ²

¹ Although the device is designed to support a 32-bit EBI data bus, the 324 package only supplies 16 balls for the EBI data bus (DATA[0:15]).

² The calibration feature is only available using the VertiCal assembly. Although the device is designed to support calibration, the 324 package does not provide balls for this feature.

- Support for external master accesses to internal addresses
- Memory controller with support for various memory types:
 - Synchronous burst SDR flash and SRAM
 - Asynchronous/legacy flash and SRAM
- Burst support (wrapped only)

- Bus monitor
 - User selectable
 - Programmable timeout period (with 8 external bus clock resolution)
- Port size configuration per chip select (16 or 32 bits)
- Port size for calibration chip select is 16 bits
- Configurable wait states (via chip selects)
- Four chip select ($\overline{CS}[0:3]$) signals
- Support for dynamic calibration with up to three calibration chip selects ($CAL_CS[0]$ and $CAL_CS[2:3]$),
- Write/byte enable ($\overline{WE}/\overline{BE}$) signals depend on the package: 324 BGA: two signals ($\overline{WE}/\overline{BE}[0:1]$)
- Configurable bus speed modes (1/2 or 1/4 of system clock frequency)
- Module disable modes for power savings
- Optional automatic CLKOUT gating to save power and reduce EMI
- Compatible with MPC5xx external bus
Refer to [Section 12.4.1.18, “Compatible with MPC5xx External Bus \(with Some Limitations\).”](#)

12.1.4 Modes of Operation

The mode of the EBI is determined by the MDIS and EXTM bits in the EBI_MCR. Refer to [Section 12.3.1.3, “EBI Module Configuration Register \(EBI_MCR\)”](#) for details. Configurable bus speed modes and debug mode are modes that the MCU can enter, in parallel to the EBI being configured in one of its module-specific modes.

12.1.4.1 Single Master Mode

In single master mode, the EBI responds to internal requests matching one of its regions, but ignores all externally-initiated bus requests. The MCU is the only master allowed to initiate transactions on the external bus in this mode; therefore, it acts as a parked master and does not have to arbitrate for the bus before starting each cycle. Single master mode is entered when $EXTM = 0$ and $MDIS = 0$ in the EBI_MCR.

NOTE

The MPC5565 does not include arbitration signals \overline{BR} , \overline{BG} , and \overline{BB} .

12.1.4.2 External Master Mode

When the MCU is in external master mode, the EBI responds to internal requests matching one of its regions, and also to external master accesses to internal address space. External master mode is entered when $EXTM = 1$ and $MDIS = 0$ in the EBI_MCR register.

Because the MPC5565 does not have arbitration, the dual-master operation (multiple masters initiating external bus cycles) is not supported. A multi-MCU system with one master and one slave is supported.

NOTE

The internal bus grant input of the EBI is tied to a negated state.

Because the MPC5565 does not have transfer size pins (TSIZ[0:1]), the SIZEN and SIZE fields in the EBI_MCR must be used for MCU-to-MCU transfers to indicate transfer size.

Refer to [Section 12.5.5, “Dual-MCU Operation with Reduced Pinout MCUs.”](#)

External master mode operation is described in [Section 12.4.2.10, “Bus Operation in External Master Mode.”](#)

12.1.4.3 Module Disable Mode

The module disable mode is used for MCU power management. The clock to the non-memory mapped logic in the EBI is stopped while in module disable mode. Requests (other than to memory-mapped logic) must not be made to the EBI while it is in module disable mode, even if the clocks have not yet been shut off. In this case, the behavior is undefined. Module disable mode is entered when MDIS = 1 in the EBI_MCR.

12.1.4.4 Configurable Bus Speed Modes

In configurable bus speed modes, the external CLKOUT frequency is reduced to 1/2 or 1/4 compared to the internal system clock frequency. The EBI continues to operate according to the EBI mode selected, except that the EBI drives and samples signals at the scaled CLKOUT frequency rate rather than the internal system clock. This mode is selected by writing the external clock control register in the system integration module (SIU_ECCR). The configurable bus speed modes supports both 1/2 or 1/4 speed modes, meaning that the external CLKOUT frequency is scaled (divided) by 2 or 4 compared with that of the internal system clock, which remains unchanged.

12.1.4.5 16-Bit Data Bus Mode

The EBI has an internal 32-bit data bus, but, for MCUs that have only 16 data bus signals pinned out, or for systems that use multiplexed signals (e.g. GPIO) on 16 of the 32 data pins, the EBI supports a 16-bit data bus mode. In this mode, DATA[0:15] are the only data signals used by the EBI. To enter 16-bit data bus mode, set the data bus mode field [DBM] in the EBI master control register (EBI_MCR[DBM]) to one. The reset value of DBM is 0.

For EBI-mastered accesses, the operation in 16-bit data bus mode (EBI_MCR[DBM] = 1, EBI_BRn[PS] = x) is similar to a chip select access to a 16-bit port in 32-bit data bus mode (EBI_MCR[DBM] = 0, EBI_BRn[PS] = 1), except for the case of an EBI-mastered non-chip select access of exactly 32-bit size.

External master accesses and EBI-mastered non-chip select accesses of exactly 32-bit size are supported using a two beat 16-bit burst for both reads and writes. Except for chip-select (CS[n]) data transmissions, all data transmissions that are not 32 bits are supported in standard non-burst fashion.

Refer to [Section 12.4.2.11, “Non-Chip-Select Burst in 16-bit Data Bus Mode.”](#)

12.1.4.6 Debug Mode

When the MCU is in debug mode, the EBI mode is unaffected and retains control of the EBI.

12.2 External Signal Description

Table 12-4 alphabetically lists the external signals used by the EBI. Refer to Chapter 2, “Signal Description,” as not all signals are implemented in all device packages.

Table 12-4. Signal Properties

Signal Name	I/O Type	Function	Pull ¹	324 ² package	496 ³ assembly
ADDR[8:11] ^{2,3}	I/O	Address bus	Up	324 ^{2,4}	496
ADDR[12:31]	I/O	Address bus	Up	324	496
$\overline{\text{BDIP}}$	Output	Burst data in progress	Up	324	496
CAL_ $\overline{\text{CS}}$ [0, 2:3] ^{2,5}	Output	Calibration chip selects	Up	—	496
CAL_ADDR[10:11] ^{2,5,6}	Output	Calibration address bus (output)	Up	—	496
CAL_ADDR[12:30] ^{2,5}	Output	Calibration address bus (output)	Up	—	496
CAL_DATA[0:15] ^{2,5}	I/O	Calibration data bus	Up	—	496
CAL_RD_ $\overline{\text{WR}}$ ^{2,5}	I/O	Calibration read/write	Up	—	496
CAL_ $\overline{\text{OE}}$ ^{2,5}	Output	Calibration output enable	Up	—	496
CAL_ $\overline{\text{TS}}$ ^{2,5}	Output	Calibration transfer start	Up	—	496
CAL_ $\overline{\text{WE}}/\overline{\text{BE}}$ [0:1] ^{2,5}	I/O	Calibration write/byte enables	Up	—	496
CLKOUT ⁷	Output	Clockout	Enabled	324	496
$\overline{\text{CS}}$ [0:3] ^{2,3}	Output	Chip selects	Up	324 ^{2,3}	496
DATA[0:15] ²	I/O	Data bus	Up	324 ²	496
DATA[16:31] ²	I/O	Data bus	Up	— ²	496
$\overline{\text{OE}}$	Output	Output enable	Up	324	496
RD_ $\overline{\text{WR}}$	I/O	Read/write	Up	324	496
$\overline{\text{TA}}$	I/O	Transfer acknowledge	Up	324	496
$\overline{\text{TEA}}$ ²	I/O	Transfer error acknowledge	Up	— ²	496
$\overline{\text{TS}}$	I/O	Transfer start	Up	324	496
$\overline{\text{WE}}/\overline{\text{BE}}$ [0:1]	Output	Write/byte enables	Up	324	496
$\overline{\text{WE}}/\overline{\text{BE}}$ [2:3] ²	Output	Write/byte enables	Up	— ²	496

¹ This column shows which signals require a weak pullup or pulldown. The EBI module does not configure the pullup or pulldown mechanisms; use the pad configuration registers (PCRs) in the System Integration Unit (SIU_PCRs) to configure the signal direction and strength requirements.

² The 324 package does not support all the muxed signals in the device design. Refer to Table 12-1 for a description of the differences between the device design and the 324 package limitations.

³ All EBI and calibration signals designed for this device are available on the VertiCal assembly.

- ⁴ ADDR[8:11] signals are muxed as alternate signals with the chip select $\overline{\text{CS}}[0:3]$ and GPIO[0:3] signals. ADDR[8:11] are also available as primary signals in the device design muxed with GPIO[4:7], however ADDR[8:11]_GPIO[4:7] are not available in 324 package. Refer to [Table 12-1](#) for more information.
- ⁵ The 324 package does not have balls for the calibration bus signals; only the VertiCal assembly currently supports the calibration bus for this device.
- ⁶ CAL_ADDR[10:11] are separate signals from the EBI block, and are muxed onto CAL_ $\overline{\text{CS}}[2:3]$ pins on MCU.
- ⁷ The CLKOUT signal is driven by the FMPLL Module.

12.2.1 Detailed Signal Descriptions

Refer to [Chapter 2, “Signal Description,”](#) as not all signals are implemented in all device packages.

Refer to [Table 12-1](#) for a description of the differences between the device design and the 324 package limitations.

12.2.1.1 Address Lines: ADDR[8:31]

The ADDR[8:31] signals specify the physical address of the bus transaction. Refer to [Table 12-2](#) for details on address bus configuration. The 24 address lines are bits 8 through 31 of the EBI’s 32-bit internal address bus. Bits 0 through 7 are internally driven by the EBI for externally initiated accesses depending on the internal slave accessed.

Refer to [Section 12.4.2.10.1, “Address Decoding for External Master Accesses,”](#) for more details.

ADDR[8:31] is driven by the EBI or an external master depending on the module that controls the external bus.

During a calibration bus access, ADDR[*n*] reflects the same values as the CAL_ADDR[*n*] signals.

12.2.1.2 Data Lines: DATA[0:31]

DATA[0:31] is driven by the EBI when it owns the external bus and it initiates a write transaction to an external device. The EBI also drives DATA[0:31] when an external master owns the external bus and initiates a read transaction to an internal module.

DATA[0:31] is driven by an external device during a read transaction from the EBI. An external master drives DATA[0:31] when it owns the bus and initiates a write transaction to an internal module or shared external memory. For 8-bit and 16-bit transactions, the unused byte lanes do not supply valid data.

In the 324 BGA package, DATA[0:15] are used to transfer data.

During a calibration bus access, the DATA bus is not driven by the EBI.

12.2.1.3 Burst Data in Progress ($\overline{\text{BDIP}}$)

$\overline{\text{BDIP}}$ is asserted by a master requesting the next data beat to follow the current data beat.

$\overline{\text{BDIP}}$ is driven by the EBI or an external master depending on the module in control of the external bus. This signal is driven by the EBI on all EBI-mastered external burst cycles, but is only sampled by burst mode memories that have a burst pin. Refer to [Section 12.4.2.5, “Burst Transfer.”](#)

12.2.1.4 Clockout (CLKOUT)

CLKOUT is a general-purpose clock output signal to connect to the clock input of SDR external memories and in some cases to the input clock of another MCU in multi-master configurations.

12.2.1.5 Chip Selects 0 through 3 ($\overline{\text{CS}}[0:3]$)

$\overline{\text{CS}}[n]$ is asserted by the master to indicate that this transaction is targeted for a particular memory bank.

The chip selects are driven by the EBI or an external master depending on who owns the external bus. $\overline{\text{CS}}$ is driven in the same clock as the assertion of $\overline{\text{TS}}$ and valid address, and is kept valid until the cycle is terminated. Refer to [Section 12.4.1.5, “Memory Controller with Support for Various Memory Types”](#) for details on chip select operation.

$\overline{\text{CS}}[0:3]$ are implemented in the VertiCal assembly and the 324 package.

During a calibration bus access, the $\overline{\text{CS}}$ signals are held negated.

12.2.1.6 Output Enable ($\overline{\text{OE}}$)

$\overline{\text{OE}}$ is used to indicate when an external memory is permitted to drive back read data. External memories must have their data output buffers off when $\overline{\text{OE}}$ is negated. $\overline{\text{OE}}$ is only asserted for chip select accesses.

$\overline{\text{OE}}$ is driven by the EBI or an external master depending on who owns the external bus. For read cycles, $\overline{\text{OE}}$ is asserted one clock after $\overline{\text{TS}}$ assertion and held until the termination of the transfer. For write cycles, $\overline{\text{OE}}$ is negated throughout the cycle.

During a calibration bus access, $\overline{\text{OE}}$ is held negated.

12.2.1.7 Read/Write ($\overline{\text{RD_WR}}$)

$\overline{\text{RD_WR}}$ indicates whether the current transaction is a read access or a write access.

$\overline{\text{RD_WR}}$ is driven by the EBI or an external master depending on who owns the external bus. $\overline{\text{RD_WR}}$ is driven in the same clock as the assertion of $\overline{\text{TS}}$ and valid address, and is kept valid until the cycle is terminated.

During a calibration bus access, $\overline{\text{RD_WR}}$ reflects the same value as the CAL_RD_WR signal.

12.2.1.8 Transfer Acknowledge ($\overline{\text{TA}}$)

$\overline{\text{TA}}$ is asserted to indicate that the slave device has received the data (and completed the access) for a write cycle, or returned data for a read cycle. If the transaction is a burst read, $\overline{\text{TA}}$ is asserted for each one of the transaction beats. For write transactions, $\overline{\text{TA}}$ is only asserted once at access completion, even if more than one write data beat is transferred.

$\overline{\text{TA}}$ is driven by the EBI when the access is controlled by the chip selects or when an external master initiates the transaction to an internal module. Otherwise, $\overline{\text{TA}}$ is driven by the slave device to which the current transaction was addressed.

During a calibration bus access, $\overline{\text{TA}}$ is held negated.

Refer to [Section 12.4.2.9, “Termination Signals Protocol”](#) for more details.

12.2.1.9 Transfer Error Acknowledge ($\overline{\text{TEA}}$)

The 324 BGA package does not support the $\overline{\text{TEA}}$ signal.

The VertiCal assembly supports the $\overline{\text{TEA}}$ signal.

During a calibration bus access, $\overline{\text{TEA}}$ is held negated.

Refer to [Section 12.4.2.9, “Termination Signals Protocol”](#) for more details.

12.2.1.10 Transfer Start ($\overline{\text{TS}}$)

$\overline{\text{TS}}$ is asserted by the current bus owner to indicate the start of a transaction on the external bus.

$\overline{\text{TS}}$ is driven by the EBI or an external master depending on who owns the external bus. $\overline{\text{TS}}$ is only asserted for the first clock cycle of the transaction, and is negated in the successive clock cycles until the end of the transaction.

During a calibration bus access, $\overline{\text{TS}}$ is held negated.

12.2.1.11 Write/Byte Enables ($\overline{\text{WE}}/\overline{\text{BE}}$)

Write enables are used to enable program operations to a particular memory. These signals can also be used as byte enables for read and write operation by setting the WEBS bit in the appropriate base register. $\overline{\text{WE}}/\overline{\text{BE}}$ are only asserted for chip select accesses.

$\overline{\text{WE}}/\overline{\text{BE}}$ signals are driven by the EBI or an external master depending on the module that controls the external bus.

The VertiCal assembly uses $\overline{\text{WE}}/\overline{\text{BE}}[0:3]$.

The 324 BGA package uses $\overline{\text{WE}}/\overline{\text{BE}}[0:1]$.

During a calibration bus access, $\overline{\text{WE}}/\overline{\text{BE}}$ signals are held negated.

Refer to [Section 12.4.1.14, “Two Write/Byte Enable \(WE/BE\) Signals — 324 BGA Package”](#) and [Section 12.4.1.13, “Four Write/Byte Enable \(WE/BE\) Signals — VertiCal Assembly”](#) for more details on the $\overline{\text{WE}}/\overline{\text{BE}}$ functionality.

12.2.1.12 Bus Busy ($\overline{\text{BB}}$), Bus Grant ($\overline{\text{BG}}$) and Bus Request ($\overline{\text{BR}}$)

The MPC5565 does not implement the $\overline{\text{BB}}$, $\overline{\text{BG}}$, or $\overline{\text{BR}}$ signals.

12.2.1.13 Transfer Size 0 through 1 (TSIZ[0:1])

TSIZ[0:1] indicates the size of the requested data transfer. Because the MPC5565 does not have transfer size pins (TSIZ[0:1]), use the SIZEN and SIZE fields in the EBI_MCR to indicate the transfer size for MCU-to-MCU transfers.

12.2.1.14 Calibration Chip Selects (CAL_ $\overline{\text{CS}}$ [0] and CAL_ $\overline{\text{CS}}$ [2:3])

CAL_ $\overline{\text{CS}}$ [*n*] is asserted by the master to indicate that this transaction is targeted for a particular memory bank on the calibration external bus.

The calibration chip selects are driven only by the EBI. External master accesses on the calibration bus are not supported. In all other aspects, the calibration chip selects behave exactly as the primary chip selects. Refer to [Section 12.4.1.5, “Memory Controller with Support for Various Memory Types”](#) for details on chip select operation.

12.2.1.15 Calibration Signals

Calibration signals are only available on the VertiCal assembly for this device. The calibration signal functions are explained in [Chapter 2, “Signal Description.”](#)

DATA is not driven by the EBI during a calibration bus access. During a calibration bus access, the non-calibration bus signals (other than DATA) are held in a negated state, with the exception of RD_ $\overline{\text{WR}}$ and ADDR, which reflect the same values shown on the calibration version of those signals. Because the $\overline{\text{TS}}$ and $\overline{\text{CS}}$ signals are held negated on the EBI (non-calibration bus) during calibration accesses, no transfer occurs on the EBI.

During a EBI bus access, the calibration bus signals (other than CAL_DATA) are held in a negated state. CAL_DATA is not driven during non-calibration accesses.

12.2.2 Signal Function and Direction by Mode

The EBI operating mode is configured using two fields in the EBI Master Control register (EBI_MCR): EXT_M and MDIS. Their settings determine which EBI signals are valid and the I/O direction. When the a signal is configured for non-EBI function in the EBI_MCR, the EBI always negates the signal if the EBI controls the corresponding pad (determined by SIU configuration). [Table 12-5](#) lists the function and direction of the external signals in each of the EBI modes of operation. The clock signals are not included because they are output only (from the FMPLL module) and are not affected by EBI modes. Refer to [Section 12.3.1.3, “EBI Module Configuration Register \(EBI_MCR\)”](#) for details on the EXT_M and MDIS bits.

Table 12-5. Signal Function (*f*) According to EBI Mode Settings

Signal Name	Modes		
	Module Disable <i>f</i> EXTM = <i>n</i> , MDIS = 1	Single Master <i>f</i> I/O Direction EXTM = 0, MDIS = 0	External Master <i>f</i> I/O Direction EXTM = 1, MDIS = 0
ADDR[8:11] ¹	non-EBI function	Address bus (output)	Address bus (I/O) ²
ADDR[12:30]	non-EBI function	Address bus (output)	Address bus (I/O) ²
$\overline{\text{BDIP}}$	non-EBI function	Burst data in progress (output) ³	
$\overline{\text{CS}}[0:3]$ ¹	non-EBI function	Chip selects (output) ³	
DATA[0:31] ⁴	non-EBI function	Data bus (I/O)	
$\overline{\text{OE}}$	non-EBI function	Output enable (output)	
RD_ $\overline{\text{WR}}$	non-EBI function	Read/write (output)	Read/write (I/O)
$\overline{\text{TA}}$	non-EBI function	Transfer acknowledge (I/O)	
$\overline{\text{TEA}}$ ⁵	non-EBI function	Transfer Error Acknowledge (I/O)	
$\overline{\text{TS}}$	non-EBI function	Transfer start (output)	Transfer start (I/O)
$\overline{\text{WE}}/\overline{\text{BE}}[0:1]$ ⁴	non-EBI function	Write/byte enables (output) ³	
$\overline{\text{WE}}/\overline{\text{BE}}[2:3]$ ⁴	non-EBI function	Write/byte enables (output) ³	
CAL_ $\overline{\text{CS}}[0, 2:3]$ ⁶	non-EBI function	Chip selects (output)	
CAL_ADDR[12:30] ⁶	non-EBI function	Calibrate the address bus (output)	
CAL_DATA[0:15] ⁶	non-EBI function	Calibrate the data bus (I/O)	
CAL_ $\overline{\text{OE}}$ ⁶	non-EBI function	Calibrate the bus to enable output	
CAL_ $\overline{\text{TS}}$ ⁶	non-EBI function	Calibrate the transfer start (output)	
CAL_ $\overline{\text{WE}}/\overline{\text{BE}}[0:1]$ ⁶	non-EBI function	Write/byte enables (output) ³	

¹ These signals are muxed with the chip select ($\overline{\text{CS}}$) signals on this device. Use the pad configuration registers (PCR) in the system integration module (SIU) to configure the balls to use the address signals or chip select signals—not both.

² All I/O signals are three-stated by the EBI when not actively involved in a transfer.

³ Although external master accesses can drive these pins, the EBI three-states the pins and does not sample them for input.

⁴ This device is designed to support a 32-bit EBI data bus (DATA[0:31]) and four write/byte enable signals ($\overline{\text{WE}}/\overline{\text{BE}}[0:3]$) on the VertiCal assembly. The 324 package provides a 16-bit EBI data bus (DATA[0:16]) and two write/byte enable signals ($\overline{\text{WE}}/\overline{\text{BE}}[0:1]$) only.

⁵ Although the device design supports the $\overline{\text{TEA}}$ signal, it is not available on the 324 package. The $\overline{\text{TEA}}$ signal is available for this device on the VertiCal assembly only.

⁶ The calibration signals for this device are available on the VertiCal assembly only.

NOTE

The open drain mode of the pads configuration module is not used for any EBI signals. For a description of how signals are driven by multiple devices in external master mode, refer to [Section 12.4.2.10, “Bus Operation in External Master Mode.”](#)

12.3 Memory Map and Register Definition

Table 12-6 is a memory map of the EBI registers.

Table 12-6. EBI Memory Map

12.3.1 Register Descriptions

12.3.1.1 Writing EBI Registers While a Transaction is in Progress

Other than the exceptions below, EBI registers must *not* be written while a transaction to the EBI (from internal or external master) is in progress (or within 2 CLKOUT cycles after a transaction has just completed, to allow internal state machines to go IDLE). In such cases, the behavior is undefined.

Exceptions that can be written while an EBI transaction is in progress are the following:

- All bits in EBI_TESR
- SIZE, SIZEN fields in EBI_MCR

Refer to [Section 12.5.1, “Bootling from External Memory,”](#) for additional information.

12.3.1.2 Separate Input Clock for Registers

The EBI registers are accessed with a clock signal separate from the clock used by the rest of the EBI. In module disable mode, the clock used by the non-register portion of the EBI is disabled to reduce power consumption. The clock signal dedicated to the registers, however, allows access to the registers even while the EBI is in the module disable mode. Flag bits in the EBI transfer error status register (EBI_TESR), however, are set and cleared with the clock used by the non-register portion of the EBI. Consequently, in module disable mode, the EBI_TESR does not have a clock signal and is therefore not writable.

12.3.1.3 EBI Module Configuration Register (EBI_MCR)

The EBI_MCR contains bits that configure various attributes associated with EBI operation.

Base (0xC3F8_4000)

Access: R/W

Figure 12-2. EBI Module Configuration Register (EBI_MCR)

The following table describes the fields in the EBI module configuration register:

Table 12-7. EBI_MCR Field Descriptions

Field	Description
0–4	Reserved.
5 SIZEN	<p>SIZE enable. The SIZEN bit enables the control of transfer size by the SIZE field for external master transactions to internal addresses.</p> <p>0 Invalid value 1 Transfer size controlled by SIZE field</p> <p>Note: You must change this value from its reset value since the device does not have TSIZ pins. Refer to Section 12.5.5.3, “Transfer Size with No TSIZ Pins (Master/Master or Master/Slave).”</p>
6–7 SIZE	<p>Transfer size. The SIZE field determines the transfer size of external master transactions to internal address space when SIZEN = 1. This field is ignored when SIZEN = 0. SIZE encoding:</p> <p>00 32-bit 01 Byte 10 16-bit 11 Invalid value</p> <p>Note: You must change this value from its reset value since the device does not have TSIZ pins. Refer to Section 12.5.5.3, “Transfer Size with No TSIZ Pins (Master/Master or Master/Slave).”</p>
8–15	Reserved.
16 ACGE	<p>Automatic CLKOUT gating enable. Enables the EBI feature of turning off CLKOUT (holding it high) during idle periods in-between external bus accesses.</p> <p>0 Automatic CLKOUT gating is disabled 1 Automatic CLKOUT gating is enabled</p>
17 EXTM	<p>External master mode. The EBI module must be enabled (MDIS = 0) to configure the external master mode. When the EBI module is disabled (MDIS = 1), the value of the EXTM bit is ignored and read as 0.</p> <p>External master mode (EXTM = 1) allows the external master device to access any internal memory area that is mapped, as long as the internal e200z6 core is fully operational.</p> <p>Single master mode (EXTM = 0) only allows internal masters can access internal memory.</p> <p>0 Single master mode (external master mode disabled) 1 External master mode</p> <p>Note: In the MPC5565, only master/slave systems support the EXTM functionality. Refer to Section 12.5.5, “Dual-MCU Operation with Reduced Pinout MCUs.”</p>
18 EARB	<p>External arbitration. Refer to Section 12.4.2.8, “Arbitration”. When EXTM = 0, the EARB bit is a don't care, and is treated as 0.</p> <p>0 Internal arbitration 1 External arbitration</p>
19–24	Reserved.
25 MDIS	<p>Module disable mode. Allows the clock to be stopped to the non-memory mapped logic in the EBI, effectively putting the EBI in a software controlled power-saving state. Refer to Section 12.1.4.3, “Module Disable Mode,” for more information. No external bus accesses can be performed when the EBI is in module disable mode (MDIS = 1).</p> <p>0 Module disable mode inactive 1 Module disable mode active</p>
26–30	Reserved.
31 DBM	<p>Data bus mode. Controls whether the EBI is in 32-bit or 16-bit data bus mode.</p> <p>0 32-bit data bus mode 1 16-bit data bus mode</p>

12.3.1.4 EBI Transfer Error Status Register (EBI_TESR)

The EBI_TESR contains a bit for each type of transfer error on the external bus. A bit set to logic 1 indicates what type of transfer error occurred since the last time the bits were cleared. Each bit can be cleared by reset or by writing a 1 to it. Writing a 0 has no effect.

This register is not writable in module disable mode due to the use of power saving clock modes.

Figure 12-4. EBI Bus Monitor Control Register (EBI_BMCR)

The following table describes the fields in the EBI bus monitor control register:

Table 12-9. EBI_BMCR Field Descriptions

Field	Description
0–15	Reserved.
16–23 BMT[0:7]	Bus monitor timing. Defines the timeout period, in 8 external bus clock resolution, for the bus monitor. Refer to Section 12.4.1.7, “Bus Monitor,” for more details on bus monitor operation. $\text{Timeout period} = \frac{2 + (8 \times \text{BMT})}{\text{External bus clock frequency}}$
24 BME	Bus monitor enable. Controls whether the bus monitor is enabled for internal to external bus cycles. Regardless of the BME value, the bus monitor is always disabled for chip select accesses, since these always use internal $\overline{\text{TA}}$ and thus have no danger of hanging the system. 0 Disable bus monitor 1 Enable bus monitor (for non-chip select accesses only)
25–31	Reserved.

12.3.1.6 EBI Base Registers 0–3 (EBI_BR n) and EBI Calibration Base Registers 0–3 (EBI_CAL_BR n)

The EBI_BR n are used to define the base address and other attributes for the corresponding chip select. The EBI_CAL_BR n are used to define the base address and other attributes for the corresponding calibration chip select.

Address: Base + 0x0010 (EBI_BR0) Access: R/W

The following table describes the fields in the EBI calibrations base register:

Table 12-10. EBI_BR n and EBI_CAL_BR n Field Descriptions

Field	Description
0–16 BA [0:16]	Base address. Compared to the corresponding unmasked address signals among ADDR[0:16] of the internal address bus to determine if a memory bank controlled by the memory controller is being accessed by an internal bus master. Note: The upper 3 bits of the base address (BA) field, EBI_BR n [0:2], and EBI_CAL_BR n [0:2], are tied to a fixed value of 001. These bits reset to their fixed value.
17–19	Reserved.
20 PS	Port size. Determines the data bus width of transactions to this chip select bank. ¹ 0 32-bit port 1 16-bit port Note: The calibration port size must be 16-bits wide.
21–24	Reserved.
25 BL	Burst length. Determines the amount of data transferred in a burst for this chip select, measured in 32-bit words. The number of beats in a burst is automatically determined by the EBI to be 4, 8, or 16 according to the port size so that the burst fetches the number of words chosen by BL. 0 8-word burst length 1 4-word burst length

Table 12-10. EBI_BR n and EBI_CAL_BR n Field Descriptions (continued)

Field	Description
26 WEBS	Write enable/byte select. Controls the functionality of the $\overline{WE}/\overline{BE}[0:3]$ signals. 0 The $\overline{WE}/\overline{BE}[0:3]$ signals function as $\overline{WE}[0:3]$. 1 The $\overline{WE}/\overline{BE}[0:3]$ signals function as $\overline{BE}[0:3]$. Note: 324-pin packages only implement $\overline{WE}/\overline{BE}[0:1]$
27 TBDIP	Toggle burst data in progress. Determines how long the \overline{BDIP} signal is asserted for each data beat in a burst cycle. Refer to Section 12.4.2.5.1, “TBDIP Effect on Burst Transfer,” for details. 0 Assert \overline{BDIP} throughout the burst cycle, regardless of wait state configuration. 1 Only assert \overline{BDIP} (BSCY + 1) external bus cycles before expecting subsequent burst data beats.
28–29	Reserved.
30 BI	Burst inhibit. Determines whether or not burst read accesses are allowed for this chip select bank. 0 Enable burst accesses for this bank. 1 Disable burst accesses for this bank. This is the default value out of reset.
31 V	Valid bit. Indicates that the contents of this base register and option register pair are valid. The appropriate \overline{CS} signal does not assert unless the corresponding V-bit is set. 0 This bank is not valid. 1 This bank is valid.

¹ In the case where EBI_MCR[DBM] is set for 16-bit data bus mode, the PS bit value is ignored and is always treated as a 1 (16-bit port).

12.3.1.7 EBI Option Registers 0–3 (EBI_OR_n) and EBI Calibration Option Registers 0–3 (EBI_CAL_OR_n)

The EBI_OR_n registers are used to define the address mask and other attributes for the corresponding chip select. The EBI_CAL_OR_n registers are used to define the address mask and other attributes for the corresponding calibration chip select.

Address: Base + 0x0014 (EBI_OR0) Access: R/W
 Base + 0x001C (EBI_OR1)
 Base + 0x0024 (EBI_OR2)

 Base + 0x0044 (EBI_CAL_OR0)
 Base + 0x004C (EBI_CAL_OR1)
 Base + 0x0054 (EBI_CAL_OR2)
 Base + 0x005C (EBI_CAL_OR3)

Figure 12-6. EBI Option Registers 0–3 (EBI_OR_n) and EBI Calibration Option Registers

The following table describes the fields in the EBI calibration option registers:

Table 12-11. EBI_OR_n and EBI_CAL_OR_n Field Descriptions

Field	Description
0–16 AM [0:16]	Address mask. Allows masking of any corresponding bits in the associated base register. Masking the address independently allows external devices of different size address ranges to be used. Any clear bit masks the corresponding address bit. Any set bit causes the corresponding address bit to be used in comparison with the address pins. Address mask bits can be set or cleared in any order in the field, allowing a resource to reside in more than one area of the address map. This field can be read or written at any time. Note: The upper 3 bits of the address mask (AM) field, EBI_OR _n [0:2], and EBI_CAL_OR _n [0:2], are tied to a fixed value of 111. These bits reset to their fixed value.
17–23	Reserved.
24–27 SCY [0:3]	Cycle length in clocks. Represents the number of wait states (external bus cycles) inserted after the address phase in the single cycle case, or in the first beat of a burst, when the memory controller handles the external memory access. Values range from 0 to 15. This is the main parameter for determining the length of the cycle. <ul style="list-style-type: none"> • The total cycle length for the first beat (including the \overline{TS} cycle): (2 + SCY) external clock cycles Refer to Section 12.5.3.1, “Example Wait State Calculation” .

Table 12-11. EBI_OR n and EBI_CAL_OR n Field Descriptions (continued)

Field	Description
28	Reserved.
29–30 BSCY [0:1]	<p>Burst beats length in clocks. This field determines the number of wait states (external bus cycles) inserted in all burst beats except the first, when the memory controller starts handling the external memory access and thus is using SCY[0:3] to determine the length of the first beat.</p> <ul style="list-style-type: none"> Total memory access length for each beat: $(1 + \text{BSCY}) \text{ External Clock Cycles}$ Total cycle length (including the $\overline{\text{TS}}$ cycle): $(2 + \text{SCY}) + [(\text{Number of Beats} - 1) \times (\text{BSCY} + 1)]$ <p>Note: The number of beats (4, 8, 16) is determined by BL and PS bits in the base register.</p> <p>00 0-clock cycle wait states (1 clock per data beat) 01 1-clock cycle wait states (2 clocks per data beat) 10 2-clock cycle wait states (3 clocks per data beat) 11 3-clock cycle wait states (4 clocks per data beat)</p>

12.4 Functional Description

12.4.1 External Bus Interface Features

12.4.1.1 32-Bit Address Bus

The 324 BGA packaged devices have 20 address lines pinned out externally (24 bits available if $\overline{\text{CS}}[0:3]$ are configured as ADDR[8:11]. Refer to the Pad Configuration Register.) A full 32-bit internal decode determines whether the transaction target asserts a chip select pin.

12.4.1.2 32-Bit Data Bus

The entire 32-bit data bus is available for both external memory accesses and transactions involving an external master in the 416 and 496BGA packaged devices.

In the 324 BGA package, the data bus is 16 bits.

12.4.1.3 16-Bit Data Bus

A 16-bit data bus mode is available via the DBM bit in EBI_MCR. Refer to [Section 12.1.4.5, “16-Bit Data Bus Mode.”](#)

12.4.1.4 Support for External Master Accesses to Internal Addresses

The EBI allows an external master to access internal address space when the EBI is configured for external master mode in the EBI_MCR. External master operations are described in detail in [Section 12.4.2.10, “Bus Operation in External Master Mode.”](#)

12.4.1.5 Memory Controller with Support for Various Memory Types

The EBI contains a memory controller that supports a variety of memory types, including

- Synchronous burst mode flash with external SRAM
- Asynchronous/legacy flash with external SRAM and a compatible interface

Each \overline{CS} bank is configured via its own pair of base and option registers. Each time an internal to external bus cycle access is requested, the internal address is compared with the base address of each valid base register (17 bits are masked). Refer to [Figure 12-7](#). If a match is found, the attributes defined for this bank in its BR and OR are used to control the memory access. If a match is found in more than one bank, the lowest bank matched handles the memory access. For example, bank 0 is selected over bank 1.

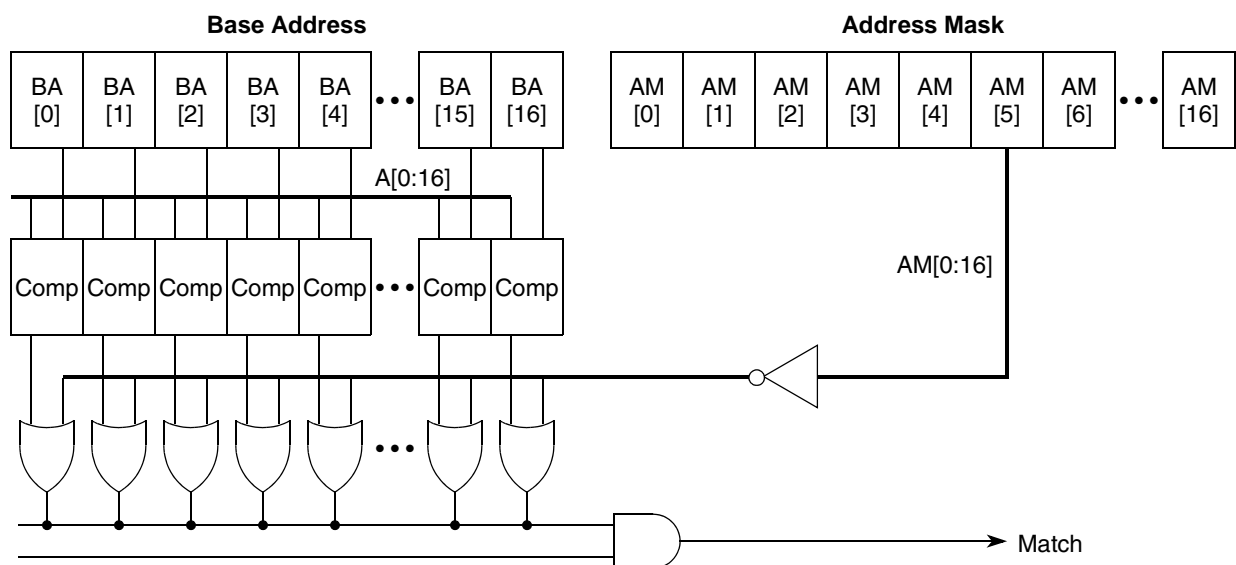

Figure 12-7. Bank Base Address and Match Structure

A match on a valid calibration chip select register overrides a match on any non-calibration chip select register, with $CAL_CS[0]$ having the highest priority. Thus the full priority of the chip selects is: $CAL_CS[0] \dots CAL_CS[3]$ and then $CS[0] \dots CS[3]$.

When a match is found on one of the chip select banks, all its attributes (from the appropriate base and option registers) are selected for the functional operation of the external memory access, such as:

- Number of wait states for a single memory access, and for any beat in a burst access
- Burst enable
- Port size for the external accessed device

Refer to [Section 12.3.1.6, “EBI Base Registers 0–3 \(EBI_BRn\) and EBI Calibration Base Registers 0–3 \(EBI_CAL_BRn\),”](#) and [Section 12.3.1.7, “EBI Option Registers 0–3 \(EBI_ORn\) and EBI Calibration Option Registers 0–3 \(EBI_CAL_ORn\),”](#) for a full description of all chip select attributes.

When no match is found on any of the chip select banks, the default transfer attributes shown in [Table 12-12](#) are used.

Table 12-12. Default Attributes for Transfers Other than Chip Select

$\overline{\text{CS}}$ Attribute	Default Value	Comment
PS	0	32-bit port size
BL	0	Burst is disabled – length is variable
WEBS	0	Write enables
TBDIP	0	Burst is disabled – length variable
BI	1	Burst inhibited
SCY	0	Transfer acknowledge ($\overline{\text{TA}}$) used – length variable
BSCY	0	Transfer acknowledge ($\overline{\text{TA}}$) used – length variable

12.4.1.6 Burst Support (Wrapped Only)

The EBI supports burst read accesses of external burstable memory. To enable bursts to a particular memory region, clear the BI (Burst Inhibit) bit in the appropriate base register. External burst lengths of 4 and 8 words are supported. Burst length is configured for each chip select by using the BL bit in the appropriate base register. Refer to [Section 12.4.2.5, “Burst Transfer”](#) for more details.

In 16-bit data bus mode ($\text{EBI_MCR}[\text{DBM}] = 1$), a special 2-beat burst case is supported for reads and writes for 32-bit non-chip select accesses only. This is to allow 32-bit coherent accesses to another MCU. Refer to [Section 12.4.2.11, “Non-Chip-Select Burst in 16-bit Data Bus Mode.”](#)

Bursting of accesses that are not controlled by the chip selects is not supported for any other case besides the special case of 32-bit accesses in 16-bit data bus mode.

Burst writes are not supported for any other case besides the special case of 32-bit non-chip select writes in 16-bit data bus mode. Internal requests to write more than 32 bits (such as a cache line) externally are broken up into separate 32-bit or 16-bit external transactions according to the port size. Refer to [Section 12.4.2.6, “Small Accesses \(Small Port Size and Short Burst Length\)”](#) for more detail on these cases.

12.4.1.7 Bus Monitor

When enabled (via the BME bit in the EBI_BMCR), the bus monitor detects when no $\overline{\text{TA}}$ assertion is received within a maximum timeout period for non-chip select accesses (that is, accesses that use external $\overline{\text{TA}}$). The timeout for the bus monitor is specified by the BMT field in the EBI_BMCR . Each time a timeout error occurs, the BMTF bit is set in the EBI_TESR . The timeout period is measured in external bus (CLKOUT) cycles. Thus the effective real-time period is multiplied (by two or four) when a configurable bus speed mode is used, even though the BMT field itself is unchanged.

12.4.1.8 Port Size Configuration per Chip Select (16 or 32 Bits)

The EBI supports memories with data widths of 16 or 32 bits. The port size (PS) for a chip select is configured using the PS bit in the base register.

12.4.1.9 Port Size Configuration per Calibration Chip Select (16 Bits)

The port size for calibration must be 16 bits wide.

12.4.1.10 Configurable Wait States

From 0 to 15 wait states can be programmed for any cycle that the memory controller generates, via the SCY bits in the appropriate option register. From zero to three wait states between burst beats can be programmed using the BSCY bits in the appropriate option register.

12.4.1.11 Four Chip Select ($\overline{\text{CS}}[0:3]$) Signals

The EBI contains four chip select signals, controlling four independent memory banks. Refer to [Section 12.4.1.5, “Memory Controller with Support for Various Memory Types,”](#) for more details on chip select bank configuration.

12.4.1.12 Support for Dynamic Calibration with Up to Three Chip Selects

The EBI contains three calibration chip select signals, controlling three independent memory banks on an optional second external bus for calibration. Refer to [Section 12.4.2.12, “Calibration Bus Operation”](#) for more details on using the calibration bus.

12.4.1.13 Four Write/Byte Enable ($\overline{\text{WE}}/\overline{\text{BE}}$) Signals — VertiCal Assembly

The functionality of the $\overline{\text{WE}}/\overline{\text{BE}}[0:3]$ signals depends on the value of the WEBS bit in the base register. Setting WEBS to 1 configures these pins as $\overline{\text{BE}}[0:3]$, while clearing them to 0 configures them as $\overline{\text{WE}}[0:3]$. $\overline{\text{WE}}[0:3]$ signals are asserted only during write accesses, while $\overline{\text{BE}}[0:3]$ signals are asserted for both read and write accesses. The timing of the $\overline{\text{WE}}/\overline{\text{BE}}[0:3]$ signals remains the same in either case.

The upper write/byte enable ($\overline{\text{WE}}/\overline{\text{BE}}[0]$) indicates that the upper eight bits of the data bus (DATA[0:7]) contain valid data during a write/read cycle. The upper middle write/byte enable ($\overline{\text{WE}}/\overline{\text{BE}}[1]$) indicates that the upper middle eight bits of the data bus (DATA[8:15]) contain valid data during a write/read cycle. The lower middle write/byte enable ($\overline{\text{WE}}/\overline{\text{BE}}[2]$) indicates that the lower middle eight bits of the data bus (DATA[16:23]) contain valid data during a write/read cycle. The lower write/byte enable ($\overline{\text{WE}}/\overline{\text{BE}}[3]$) indicates that the lower eight bits of the data bus (DATA[24:31]) contain valid data during a write/read cycle.

The write/byte enable lines affected in a transaction for a 32-bit port (PS = 0) and a 16-bit port (PS = 1) are shown in [Table 12-13](#). Only big endian byte ordering is supported by the EBI.

12.4.1.14 Two Write/Byte Enable ($\overline{\text{WE}}/\overline{\text{BE}}$) Signals — 324 BGA Package

The functionality of the $\overline{\text{WE}}/\overline{\text{BE}}[0:1]$ signals depends on the value of the WEBS bit in the corresponding base register. Setting WEBS to 1 configures these pins as $\overline{\text{BE}}[0:1]$, while clearing them to 0 configures the pins to $\overline{\text{WE}}[0:1]$. $\overline{\text{WE}}[0:1]$ signals are asserted only during write accesses, while $\overline{\text{BE}}[0:1]$ signals are asserted for both read and write accesses. The timing of the $\overline{\text{WE}}/\overline{\text{BE}}[0:1]$ signals remains the same in both cases.

The upper write/byte enable ($\overline{WE}/\overline{BE}[0]$) indicates that the upper eight bits of the data bus (DATA[0:7]) contain valid data during a write/read cycle. The lower write/byte enable ($\overline{WE}/\overline{BE}[1]$) indicates that the lower eight bits of the data bus (DATA[8:15]) contain valid data during a write/read cycle.

The write/byte enable lines affected in a transaction are shown in [Table 12-13](#). Only big endian byte ordering is supported by the EBI.

Table 12-13. Write/Byte Enable Signals Function -- 324 BGA

Transfer Size	TSIZ[0:1] ¹	Address		16-Bit Port Size ²	
		A[30]	A[31]	$\overline{WE}/\overline{BE}[0]$	$\overline{WE}/\overline{BE}[1]$
Byte	01	0	0	X	—
	01	0	1	—	X
	01	1	0	X	—
	01	1	1	—	X
16-bit	10	0	0	X	X
	10	1	0	X	X
32-bit	00	0	0	X ³	X ³
Burst	00	0	0	X	X

¹ TSIZ is not available on the MPC5565.

² Also applies when DBM = 1 for 16-bit data bus mode.

³ This case consists of two 16-bit external transactions, but for both transactions the $\overline{WE}/\overline{BE}[0:1]$ signals are the only $\overline{WE}/\overline{BE}$ signals affected.

NOTE: “X” indicates that valid data is transferred on these bits.

12.4.1.15 Configurable Bus Speed Clock Modes

The EBI supports configurable bus speed clock modes. Refer to [Section 12.1.4.4, “Configurable Bus Speed Modes,”](#) for more details on this feature.

12.4.1.16 Stop and Module Disable Modes for Power Savings

Refer to [Section 12.1.4, “Modes of Operation,”](#) for a description of the power saving modes.

12.4.1.17 Optional Automatic CLKOUT Gating

The EBI has the ability to hold the external CLKOUT pin high when the EBI’s internal master state machine is idle and no requests are pending. The EBI outputs a signal to the pads logic in the MCU to disable CLKOUT. This feature is disabled out of reset, and can be enabled or disabled by the ACGE bit in the EBI_MCR.

NOTE

This feature must be disabled for multi-master systems. In those cases, one master is getting its clock source from the other master and needs the other master to stay valid continuously.

12.4.1.18 Compatible with MPC5xx External Bus (with Some Limitations)

The EBI is compatible with the external bus of the MPC5xx parts, meaning that it supports most devices supported by the MPC5xx family of parts. However, there are some differences between this EBI and that of the MPC5xx parts that the user needs to be aware of before assuming that an MPC5xx-compatible device works with this EBI. Refer to [Section 12.5.6, “Summary of Differences from MPC5xx,”](#) for details.

NOTE

Due to testing and complexity concerns, multi-master (or master/slave) operation between an MPC55xx and MPC5xx is not guaranteed.

12.4.2 External Bus Operations

The following sections provide a functional description of the external bus, the bus cycles provided for data transfer operations, bus arbitration, and error conditions.

12.4.2.1 External Clocking

The CLKOUT signal sets the frequency of operation for the bus interface directly. Internally, the MCU uses a phase-locked loop (PLL) circuit to generate a master clock for all of the MCU circuitry (including the EBI) which is phase-locked to the CLKOUT signal. In general, all signals for the EBI are specified with respect to the rising-edge of the CLKOUT signal, and they are guaranteed to be sampled as inputs or changed as outputs with respect to that edge.

12.4.2.2 Reset

Upon detection of internal reset, the EBI immediately terminates all transactions.

12.4.2.3 Basic Transfer Protocol

The basic transfer protocol defines the sequence of actions that must occur on the external bus to perform a complete bus transaction. A simplified scheme of the basic transfer protocol is shown in [Figure 12-8](#).

Figure 12-8. Basic Transfer Protocol

The arbitration phase is where bus ownership is requested and granted. This phase is not needed in single master mode because the EBI is the permanent bus owner in this mode.

The address transfer phase specifies the address for the transaction and the transfer attributes that describe the transaction. The signals related to the address transfer phase are \overline{TS} , ADDR, $\overline{CS}[0:3]$, RD_ \overline{WR} , and \overline{BDIP} . The address \overline{TA} and its related signals (with the exception of \overline{TS} , \overline{BDIP}) are driven on the bus with the assertion of the \overline{TS} signal, and kept valid until the bus master receives \overline{TA} asserted (the EBI holds them one cycle beyond \overline{TA} for writes and external \overline{TA} accesses). For writes with internal \overline{TA} , RD_ \overline{WR} is not held one cycle past \overline{TA} .

The data transfer phase performs the transfer of data, from master to slave (in write cycles) or from slave to master (on read cycles), if any is to be transferred. The data phase may transfer a single beat of data (1-4 bytes) for non-burst operations or a 2-beat (special EBI_MCR[DBM] = 1 case only), 4-beat, 8-beat, or 16-beat burst of data (2 or 4 bytes per beat depending on port size) when burst is enabled. On a write cycle, the master must not drive write data until after the address transfer phase is complete. This is to avoid electrical contentions when switching between drivers. The master must start driving write data one cycle after the address transfer cycle. The master can stop driving the data bus as soon as it samples the \overline{TA} line asserted on the rising edge of CLKOUT. To facilitate asynchronous write support, the EBI keeps driving valid write data on the data bus until 1 clock after the rising edge where RD_ \overline{WR} (and \overline{WE} for chip select accesses) are negated.

Refer to [Figure 12-14](#) for an example of write timing. On a read cycle, the master accepts the data bus contents as valid on the rising edge of the CLKOUT in which the \overline{TA} signal is sampled asserted. Refer to [Figure 12-10](#) for an example of read timing.

The termination phase is where the cycle is terminated by the assertion of either \overline{TA} (normal termination) or \overline{TEA} (termination with error). Termination is discussed in detail in [Section 12.4.2.9, “Termination Signals Protocol.”](#)

12.4.2.4 Single-Beat Transfer

The flow and timing diagrams in this section assume that the EBI is configured in single master mode. Therefore, arbitration is not needed and is not shown in these diagrams. Refer to [Section 12.4.2.10, “Bus Operation in External Master Mode,”](#) to read how the flow and timing diagrams change for external master mode.

12.4.2.4.1 Single-Beat Read Flow

The handshakes for a single beat read cycle are illustrated in the following flow and timing diagrams.

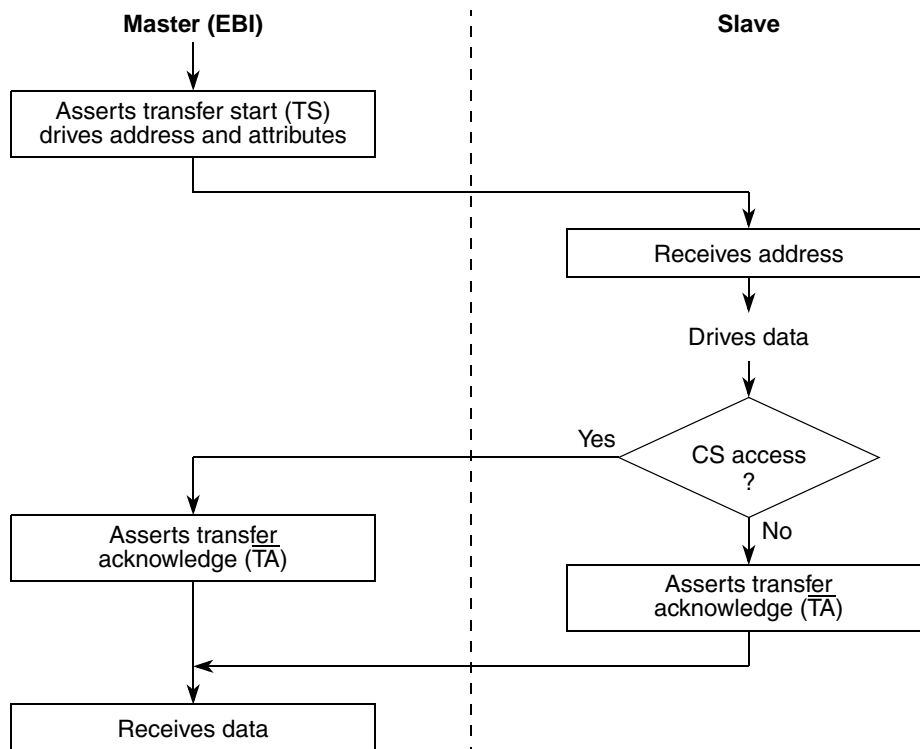

Figure 12-9. Basic Flow Diagram of a Single-Beat Read Cycle

Figure 12-10. Single-Beat 32-bit Read Cycle, $\bar{C}S$ Access, Zero Wait States

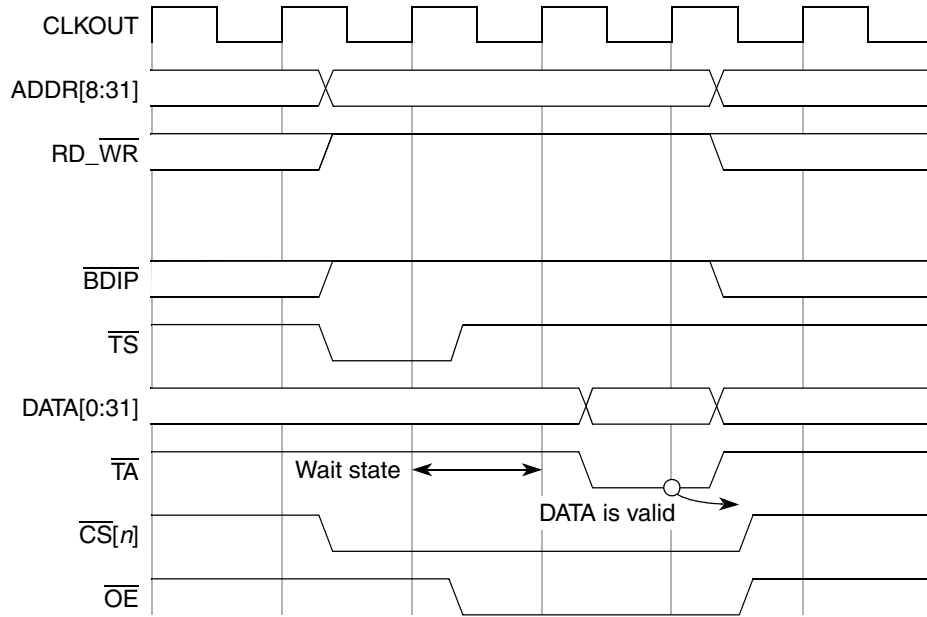

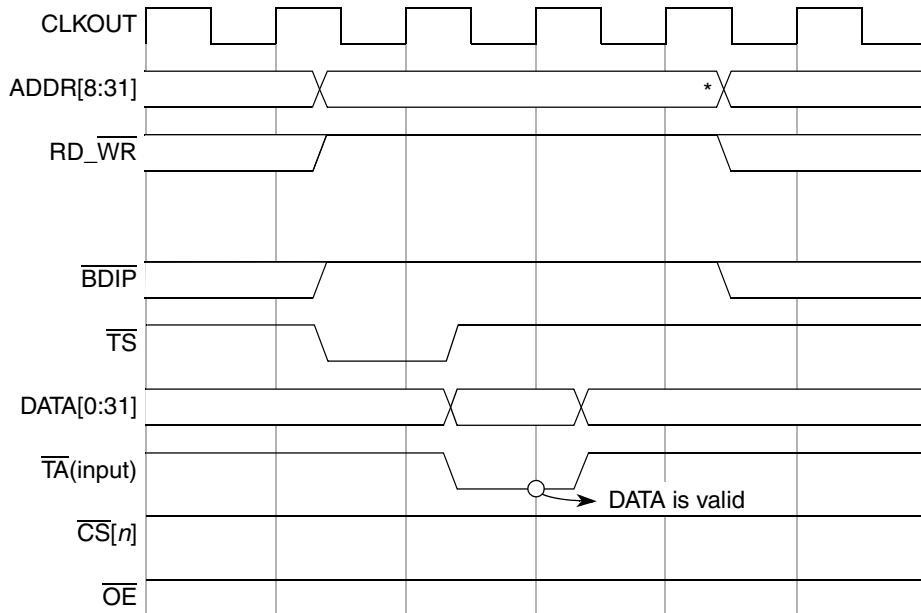

Figure 12-11. Single-Beat 32-bit Read Cycle, \overline{CS} Access, One Wait State

* The EBI drives address and control signals an extra cycle because it uses a latched version of the external \overline{TA} (1 cycle delayed) to terminate the cycle.

Figure 12-12. Single-Beat 32-bit Read Cycle, Non- \overline{CS} Access, Zero Wait States

12.4.2.4.2 Single-Beat Write Flow

The handshakes for a single beat write cycle are illustrated in the following flow and timing diagrams.

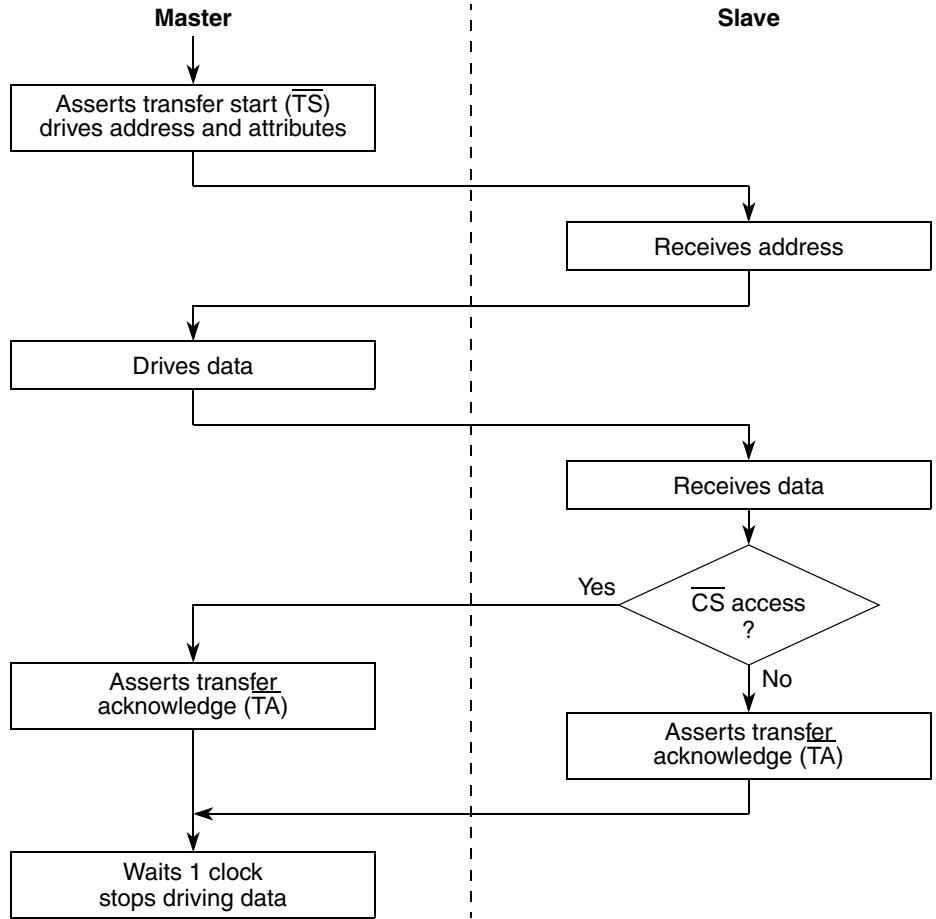

Figure 12-13. Basic Flow Diagram of a Single-Beat Write Cycle

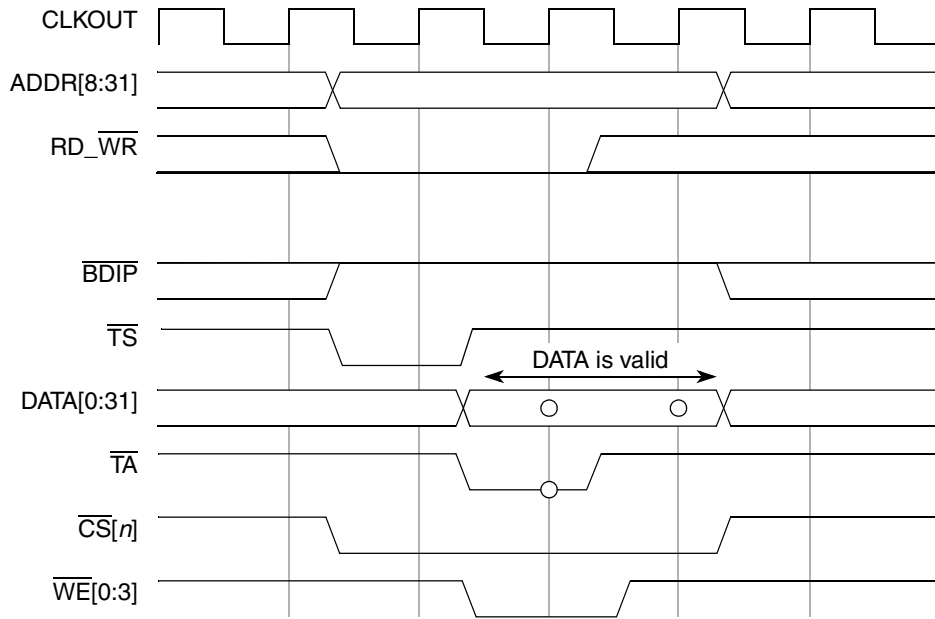

Figure 12-14. Single-Beat 32-bit Write Cycle, \overline{CS} Access, Zero Wait States

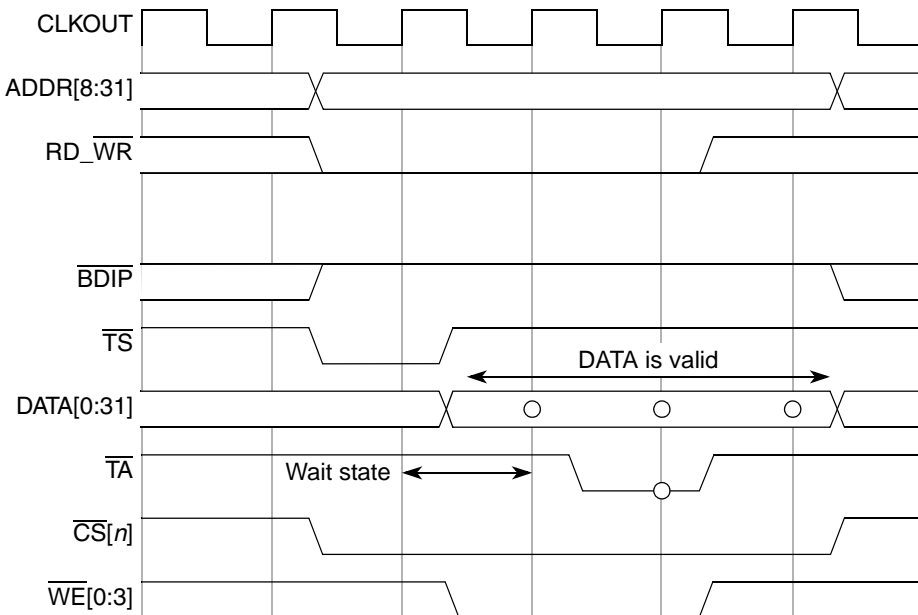

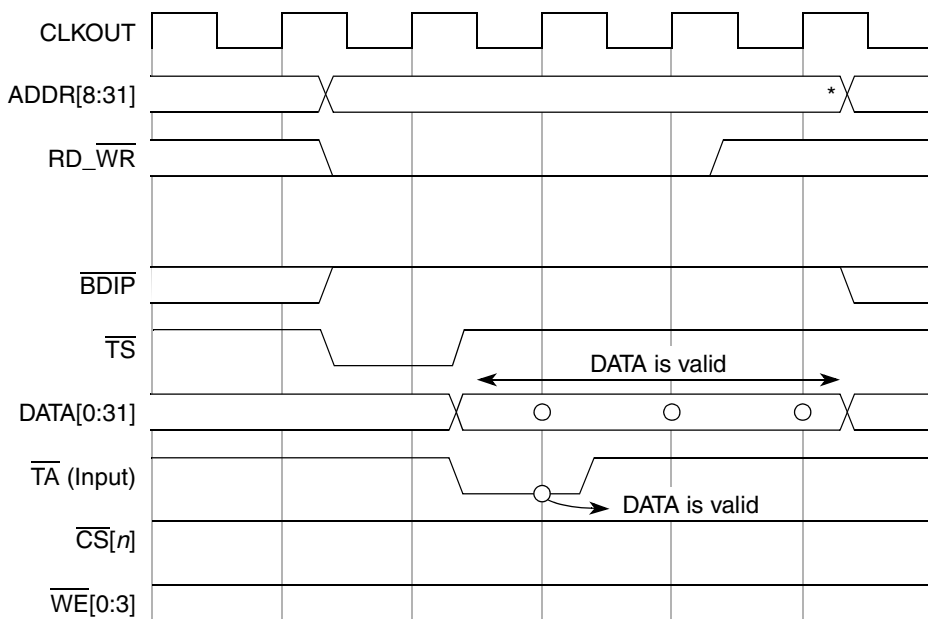

Figure 12-15. Single-Beat 32-bit Write Cycle, \overline{CS} Access, One Wait State

* The EBI drives address and control signals an extra cycle because it uses a latched version of the external \overline{TA} (1 cycle delayed) to terminate the cycle.

Figure 12-16. Single-Beat 32-bit Write Cycle, Non- \overline{CS} Access, Zero Wait States

12.4.2.4.3 Back-to-Back Accesses

Due to internal bus protocol, one dead cycle is necessary between back-to-back external bus accesses that are not part of a set of small accesses (refer to [Section 12.4.2.6, “Small Accesses \(Small Port Size and Short Burst Length\)”](#) for small access timing). A dead cycle refers to a cycle between the \overline{TA} of a previous transfer and the \overline{TS} of the next transfer.

NOTE

In some cases, \overline{CS} remains asserted during this dead cycle, such as the cases of back-to-back writes or read-after-write to the same chip-select. Refer to [Figure 12-20](#) and [Figure 12-21](#).

Besides this dead cycle, in most cases, back-to-back accesses on the external bus do not cause any change in the timing from that shown in the previous diagrams, and the two transactions are independent of each other. The only exceptions to this are as follows:

- Back-to-back accesses where the first access ends with an externally-driven \overline{TA} or \overline{TEA} . In these cases, an extra cycle is required between the end of the first access and the \overline{TS} assertion of the second access. Refer to [Section 12.4.2.9, “Termination Signals Protocol,”](#) for more details.

[Figure 12-17](#), [Figure 12-18](#), and [Figure 12-19](#) show a few examples of back-to-back accesses on the external bus.

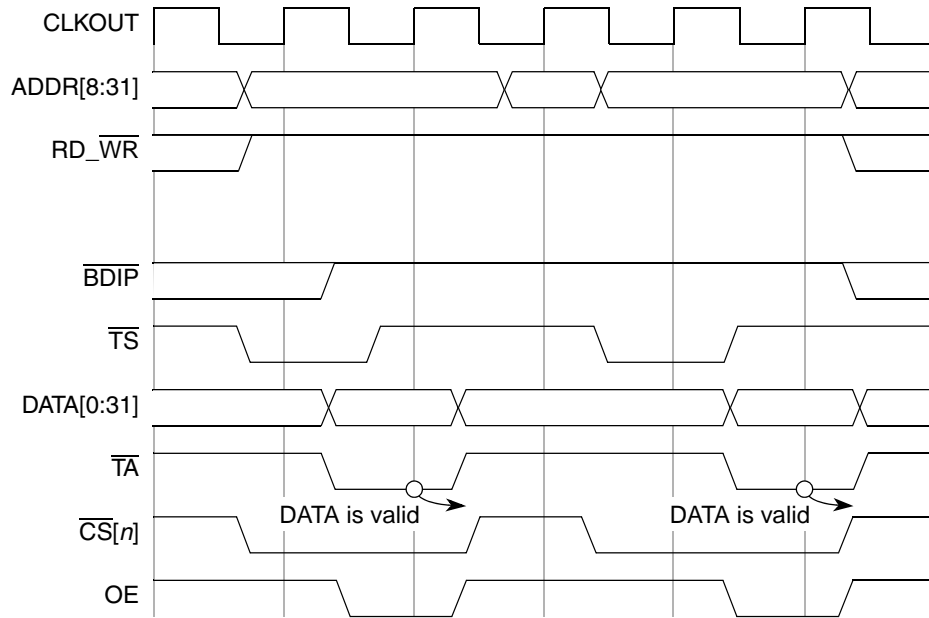

Figure 12-17. Back-to-Back 32-bit Reads to the Same \overline{CS} Bank

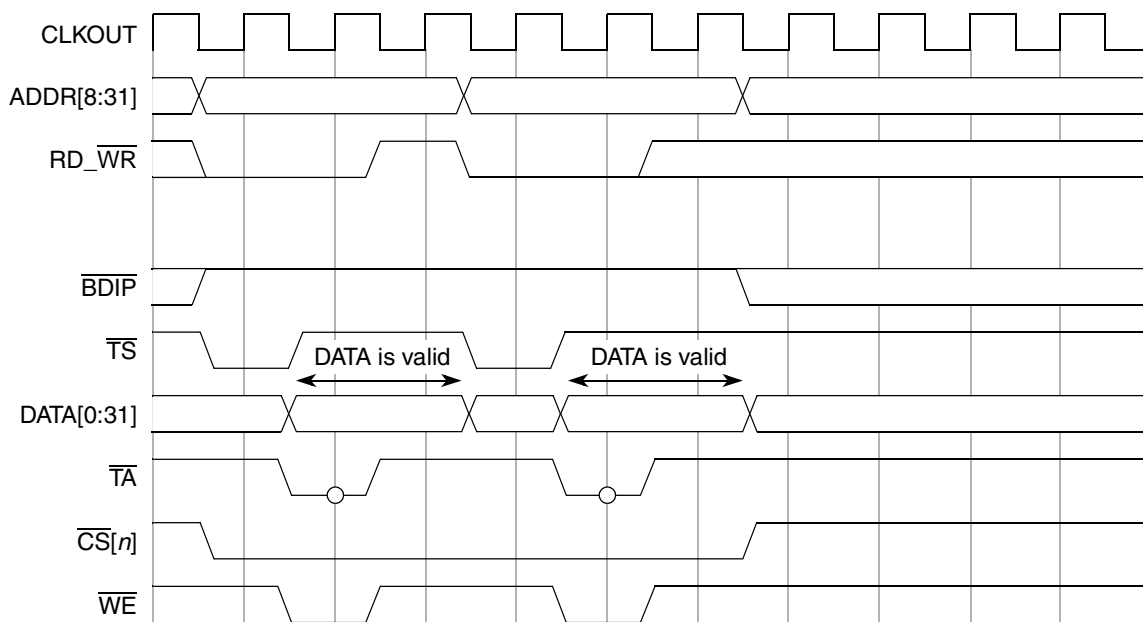

Figure 12-20. Back-to-Back 32-bit Writes to the Same CS Bank

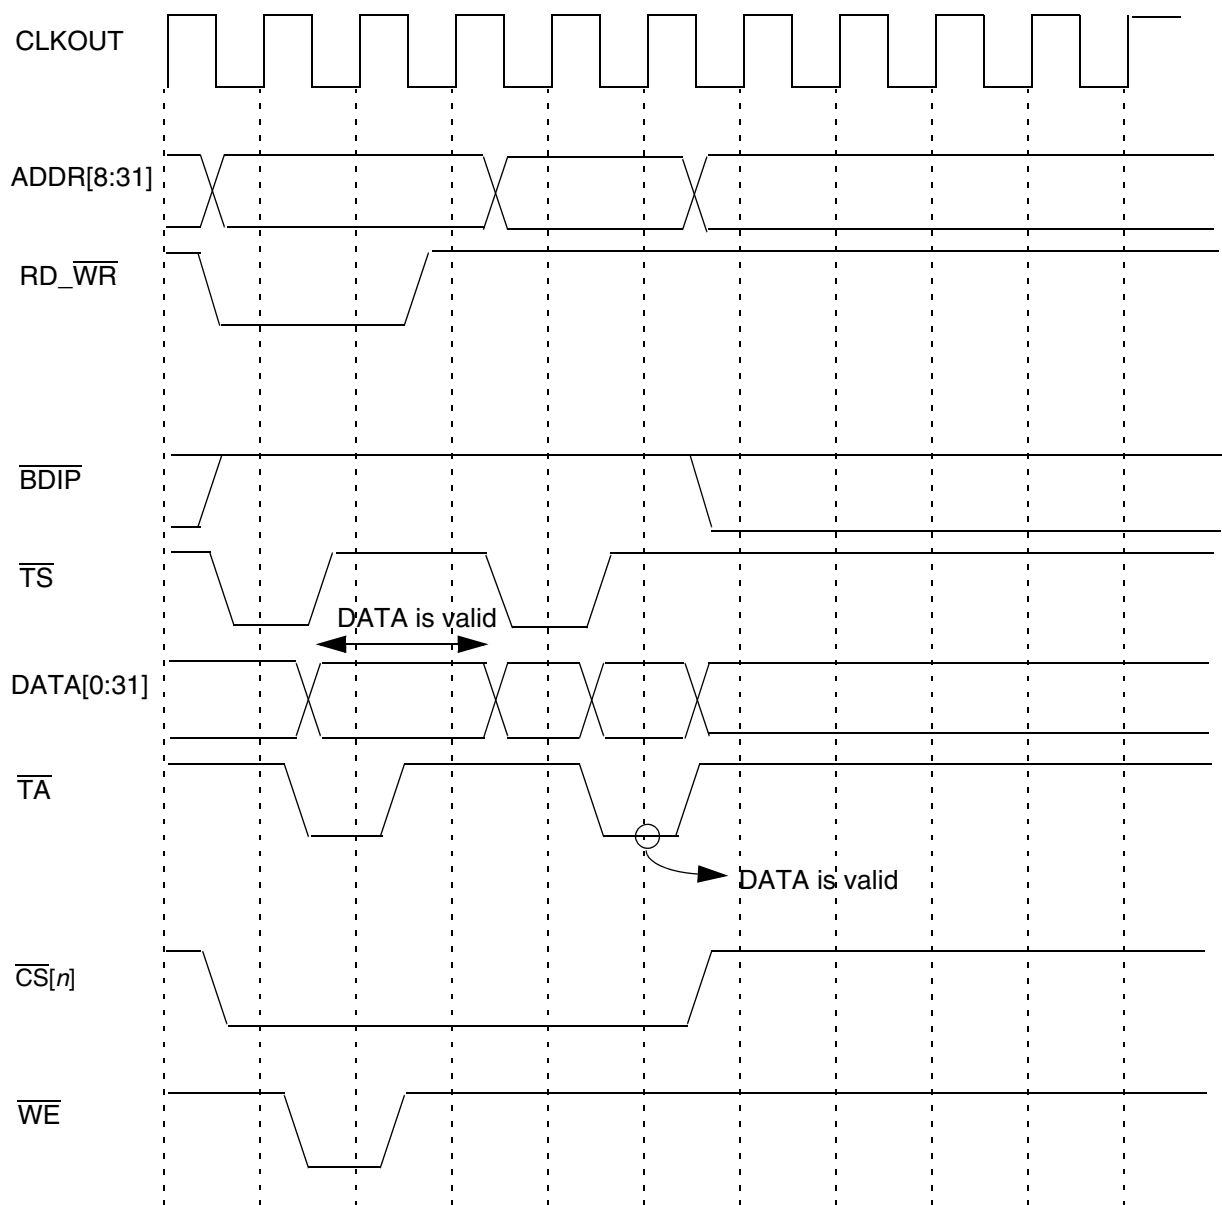

Figure 12-21. Read-After-Write to the Same \overline{CS} Bank

12.4.2.5 Burst Transfer

The EBI supports wrapping 32-byte critical-doubleword-first burst transfers. Bursting is supported only for internally-requested cache-line size (32-byte) read accesses to external devices that use the chip selects¹. Accesses from an external master or to devices operating without a chip select are always single beat. If an internal request to the EBI indicates a size of less than 32 bytes, the request is fulfilled by running one or more single-beat external transfers, not by an external burst transfer.

1. Except for the special case of a 32-bit non-chip select access in 16-bit data bus mode. Refer to Section 12.4.2.11.

An 8-word wrapping burst reads eight 32-bit words by supplying a starting address that points to one of the words (doubleword aligned) and requiring the memory device to sequentially drive each word on the data bus. The selected slave device must internally increment ADDR[27:29] (also ADDR[30] in the case of a 16-bit port size device) of the supplied address for each transfer, until the address reaches an 8-word boundary, and then wrap the address to the beginning of the 8-word boundary. The address and transfer attributes supplied by the EBI remain stable during the transfers, and the EBI terminates each beat transfer by asserting TA. The EBI requires that addresses be aligned to a doubleword boundary on all burst cycles.

Table 12-14 shows the burst order of beats returned for an 8-word burst to a 32-bit port.

Table 12-14. Wrap Bursts Order

Burst Starting Address ADDR[27:28]	Burst Order (Using 32-bit Port Size)
00	word0 → word1 → word2 → word3 → word4 → word5 → word6 → word7
01	word2 → word3 → word4 → word5 → word6 → word7 → word0 → word1
10	word4 → word5 → word6 → word7 → word0 → word1 → word2 → word3
11	word6 → word7 → word0 → word1 → word2 → word3 → word4 → word5

The general case of burst transfers assumes that the external memory has 32-bit port size and 8-word burst length. The EBI can also burst from 16-bit port size memories, taking twice as many external beats to fetch the data as compared to a 32-bit port with the same burst length. The EBI can also burst from 16-bit or 32-bit memories that have a 4-word burst length (BL = 1 in the appropriate base register). In this case, two external 4-word burst transfers (wrapping on 4-word boundary) are performed to fulfill the internal 8-word request. This operation is considered atomic by the EBI, so the EBI does not allow other unrelated master accesses or bus arbitration to intervene between the transfers. For more details and a timing diagram, refer to Section 12.4.2.6.3, “Small Access Example #3: 32-byte Read to 32-bit Port with BL = 1.”

During burst cycles, the $\overline{\text{BDIP}}$ (burst data in progress) signal is used to indicate the duration of the burst data. During the data phase of a burst read cycle, the EBI receives data from the addressed slave. If the EBI needs more than one data, it asserts the $\overline{\text{BDIP}}$ signal. Upon receiving the data prior to the last data, the EBI negates $\overline{\text{BDIP}}$. Thus, the slave stops driving new data after it receives the negation of $\overline{\text{BDIP}}$ on the rising edge of the clock. Some slave devices have their burst length and timing configurable internally and thus may not support connecting to a $\overline{\text{BDIP}}$ pin. In this case, $\overline{\text{BDIP}}$ is driven by the EBI normally, but the output is ignored by the memory and the burst data behavior is determined by the internal configuration of the EBI and slave device. When the TBDIP bit is set in the appropriate base register, the timing for $\overline{\text{BDIP}}$ is altered. Refer to Section 12.4.2.5.1, “TBDIP Effect on Burst Transfer,” for this timing.

Since burst writes are not supported by the EBI¹, the EBI negates $\overline{\text{BDIP}}$ during write cycles.

1. Except for the special case of a 32-bit non-chip select access in 16-bit data bus mode. Refer to Section 12.4.2.11.

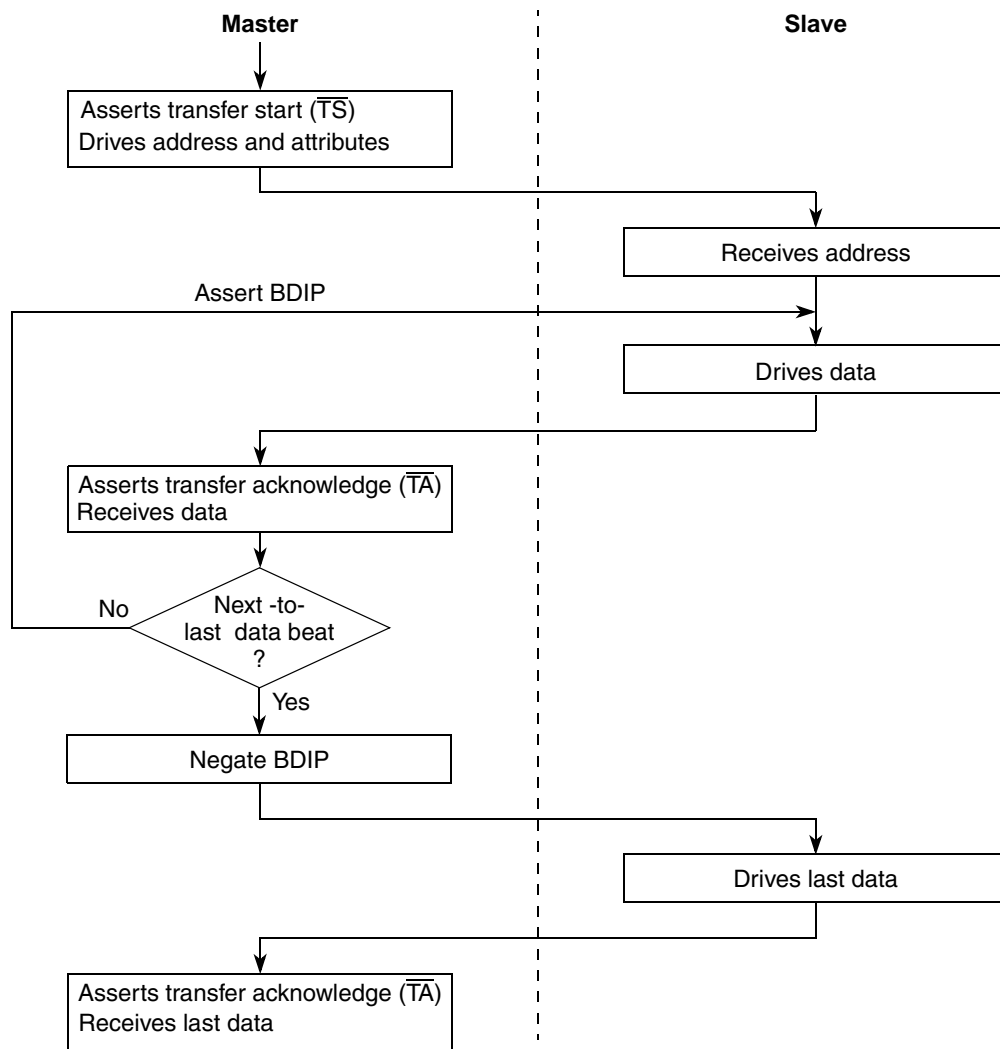

Figure 12-22. Basic Flow Diagram of a Burst Read Cycle

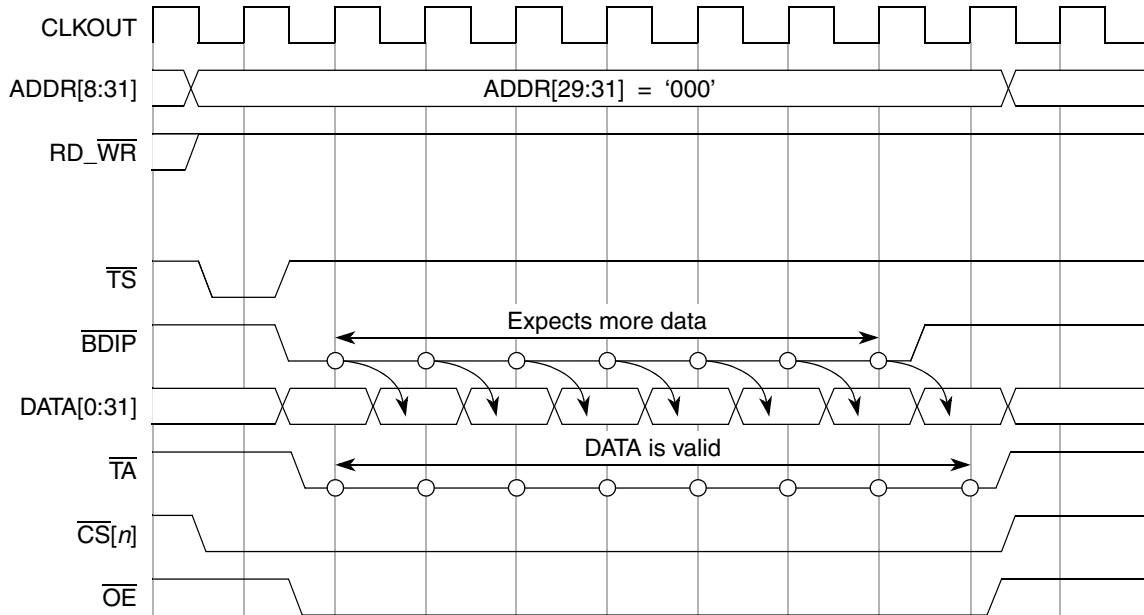

Figure 12-23. Burst 32-bit Read Cycle, Zero Wait States

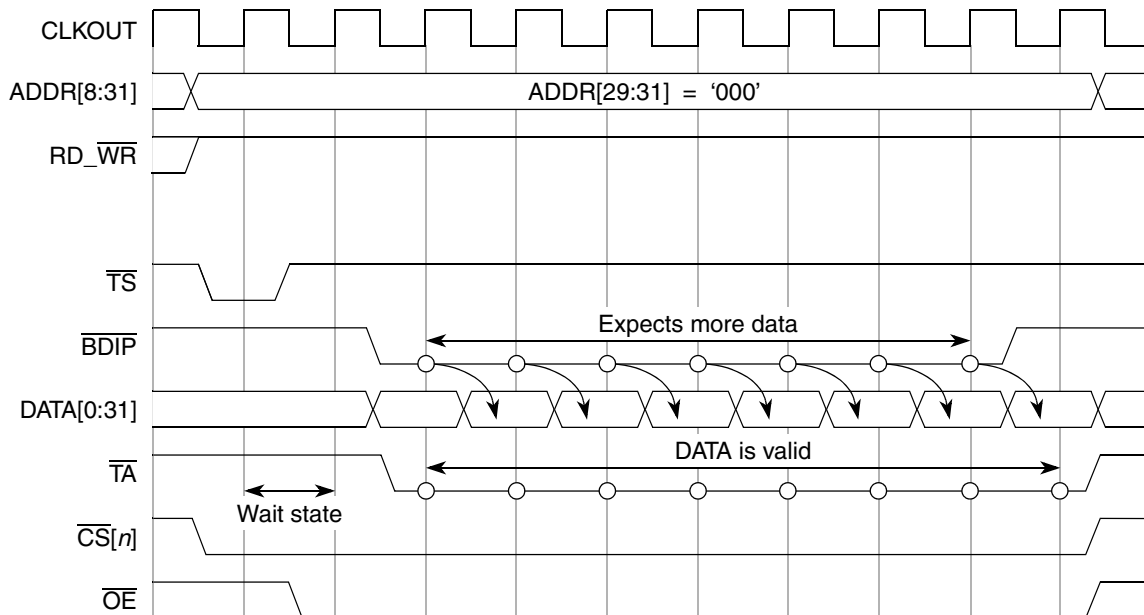

Figure 12-24. Burst 32-bit Read Cycle, One Initial Wait State

12.4.2.5.1 TBDIP Effect on Burst Transfer

Some memories require different timing on the $\overline{\text{BDIP}}$ signal than the default to run burst cycles. Using the default value of $\text{TBDIP} = 0$ in the appropriate EBI base register results in $\overline{\text{BDIP}}$ being asserted ($\text{SCY} + 1$) cycles after the address transfer phase, and being held asserted throughout the cycle regardless of the wait states between beats (BSCY). [Figure 12-25](#) shows an example of the $\text{TBDIP} = 0$ timing for a four-beat burst with $\text{BSCY} = 1$.

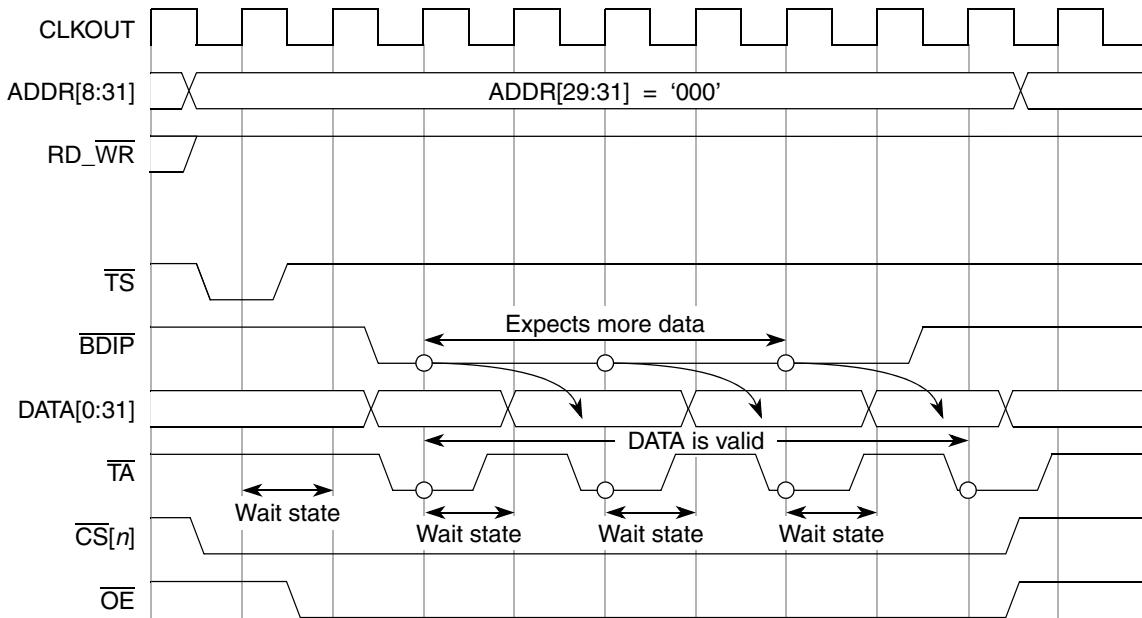

Figure 12-25. Burst 32-bit Read Cycle, One Wait State between Beats, $\text{TBDIP} = 0$

When using $TBDIP = 1$, the \overline{BDIP} behavior changes to toggle between every beat when $BSCY$ is a non-zero value. Figure 12-26 shows an example of the $TBDIP = 1$ timing for the same four-beat burst shown in Figure 12-25.

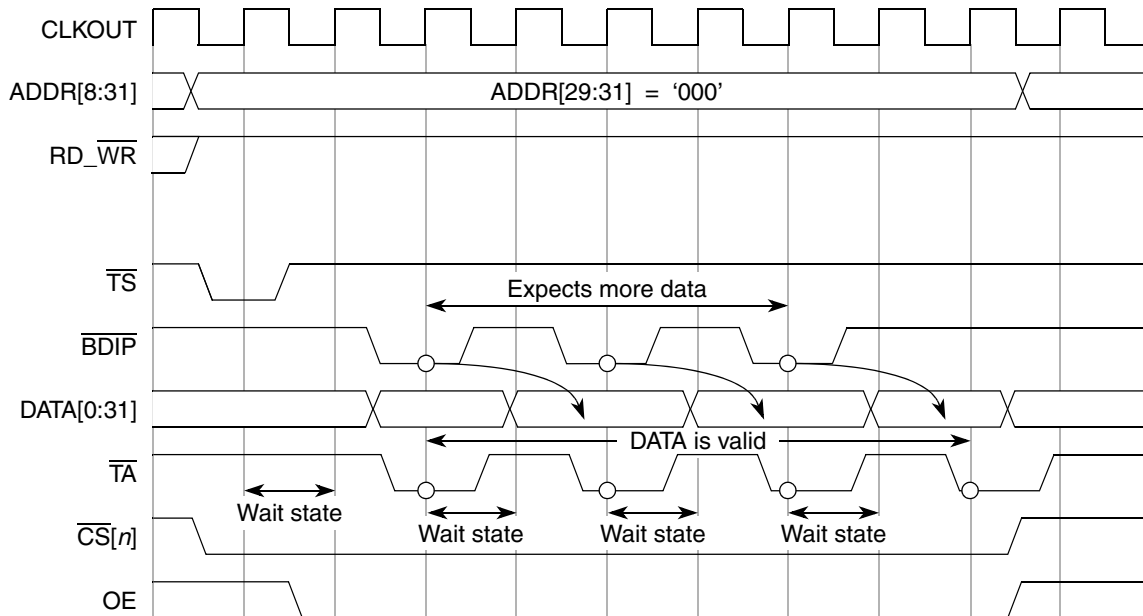

Figure 12-26. Burst 32-bit Read Cycle, One Wait State between Beats, $TBDIP = 1$

12.4.2.6 Small Accesses (Small Port Size and Short Burst Length)

In this context, a small access refers to an access whose burst length and port size are such that the number of bytes requested by the internal master cannot all be fetched (or written) in one external transaction. This is the case when the base register's burst length bit ($EBI_BRn[BL]$) and port size bit ($EBI_BRn[PS]$) are set such that one of two situations occur:

- Burst accesses are inhibited and the number of bytes requested by the master is greater than the port size (16 or 32 bit) can accommodate in a single access.
- Burst accesses are enabled and the number of bytes requested by the master is greater than the selected burst length (4 words or 8 words).

If this is the case, the EBI initiates multiple transactions until all the requested data is transferred. All the transactions initiated to complete the data transfer are considered as an atomic transaction, so the EBI does not allow other unrelated master accesses to intervene between the transfers. In external master mode, this means that the EBI keeps \overline{BB} asserted and does not grant the bus to another master until the atomic transaction is complete.

Table 12-15 shows all the combinations of burst length, port size, and requested byte count that cause the EBI to run multiple external transactions to fulfill the request.

Table 12-15. Small Access Cases

Byte Count Requested by Internal Master	Burst Length	Port Size	# External Accesses to Fulfill Request
Non-burstable Chip-Select Banks (BI = 1) or Non-Chip-Select Access			
4	1 beat	16-bit	2/1 ¹
8	1 beat	32-bit	2
8	1 beat	16-bit	4
32	1 beat	32-bit	8
32	1 beat	16-bit	16
Burstable Chip-Select Banks (BI = 0)			
32	4 words	16-bit (8 beats), 32-bit (4 beats)	2

¹ In 32-bit data bus mode (DBM = 0 in EBI_MCR), two accesses are performed. In 16-bit data bus mode (DBM = 1), one 2-beat burst access is performed and this is not considered a small access case. Refer to Section 12.4.2.11, “Non-Chip-Select Burst in 16-bit Data Bus Mode” for this special DBM = 1 case.

In most cases, the timing for small accesses is the same as for normal single-beat and burst accesses, except that multiple back-to-back external transfers are executed for each internal request. These transfers have no additional dead cycles in-between that are not present for back-to-back stand-alone transfers except for the case of writes with an internal request size greater than 64 bits, discussed in Section 12.4.2.6.2, “Small Access Example #2: 32-byte Write with External TA.”

The following sections show a few examples of small accesses. The timing for the remaining cases in Table 12-15 can be extrapolated from these and the other timing diagrams in this document.

12.4.2.6.1 Small Access Example #1: 32-bit Write to 16-bit Port

Figure 12-27 shows an example of a 32-bit write to a 16-bit port, requiring two 16-bit external transactions.

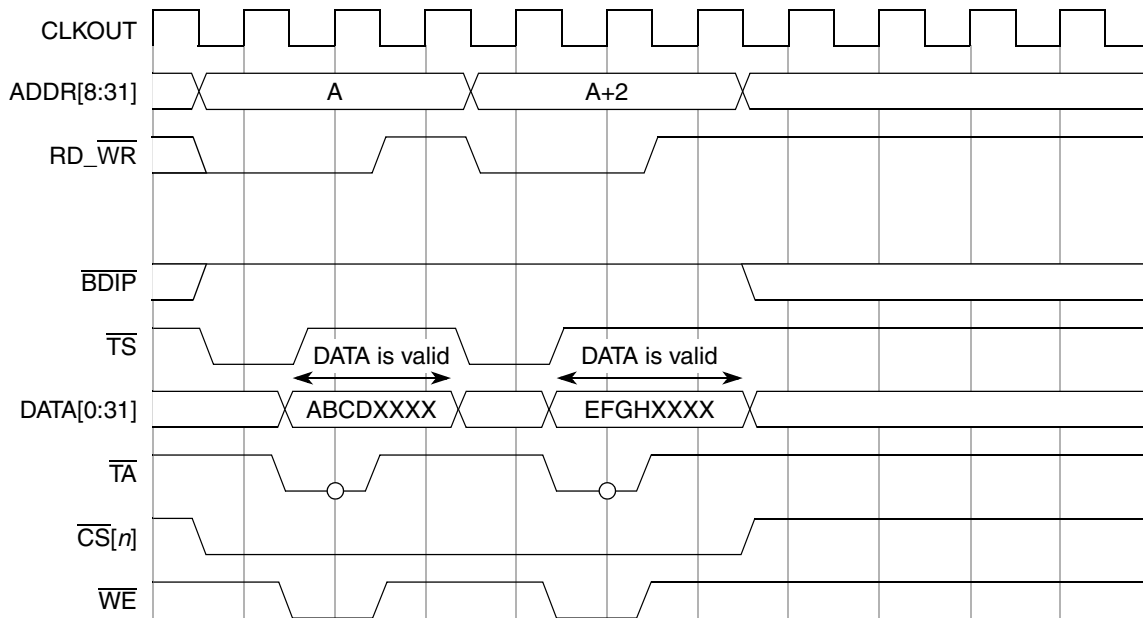

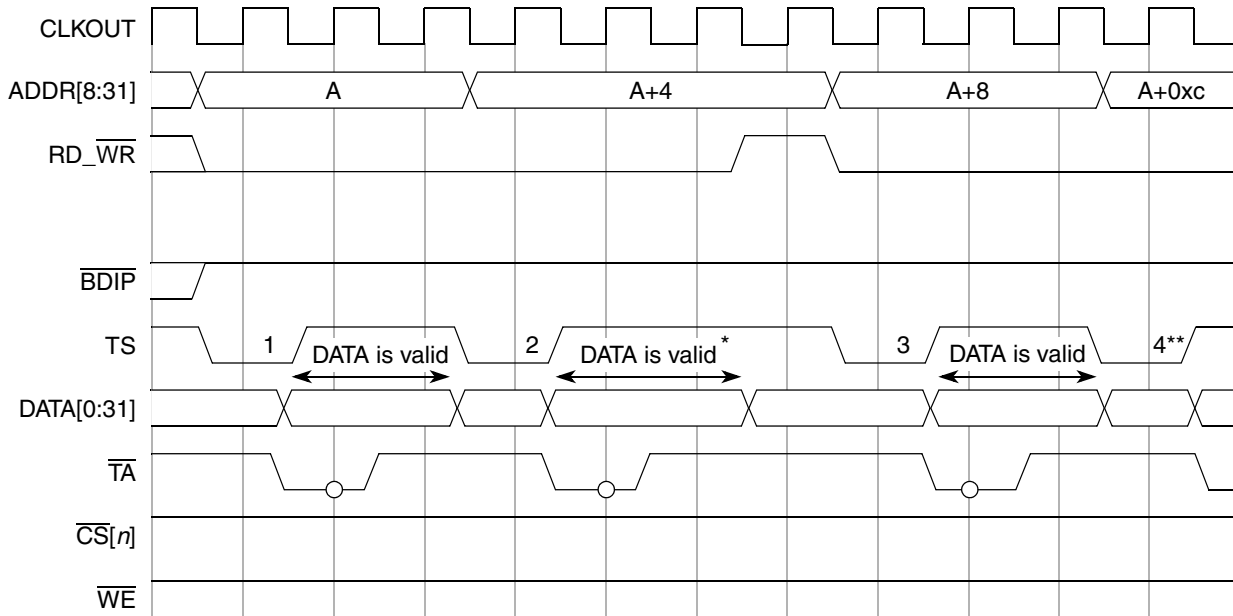

Figure 12-27. Single Beat 32-bit Write Cycle, 16-bit Port Size, Basic Timing

12.4.2.6.2 Small Access Example #2: 32-byte Write with External \overline{TA}

Figure 12-28 shows an example of a 32-byte write to a non-chip select device, such as an external master, using external \overline{TA} , requiring eight 32-bit external transactions. Due to the use of external \overline{TA} , RD_WR does not toggle between the accesses unless that access is the end of a 64-bit boundary. In this case, an extra cycle is required between \overline{TA} and the next \overline{TS} to get the next 64-bits of write data internally and RD_WR negates during this extra cycle.

* This extra cycle is required after accesses 2, 4, and 6 to get the next 64-bits of internal write data.

** Four more external accesses (not shown) are required to complete the internal 32-byte request. The timing of these is the same as accesses 1-4 shown in this diagram.

Figure 12-28. 32-Byte Write Cycle with External \overline{TA} , Basic Timing

12.4.2.6.3 Small Access Example #3: 32-byte Read to 32-bit Port with BL = 1

Figure 12-29 shows an example of a 32-byte read to a 32-bit burst enabled port with burst length of 4 words, requiring two 16-byte external transactions. For this case, the address for the second 4-word burst access is calculated by adding 0x10 to the lower 5 bits of the first address (no carry), and then masking out the lower 4 bits to fix them at zero.

Table 12-16. Examples of 4-word Burst Addresses

1st Address	Lower 5 bits of 1st Address + 0x10 (no carry)	Final 2nd Address (After Masking Lower 4 Bits)
0x000	0x10	0x10
0x008	0x18	0x10
0x010	0x00	0x00
0x018	0x08	0x00
0x020	0x30	0x30
0x028	0x38	0x30
0x030	0x20	0x20
0x038	0x28	0x20

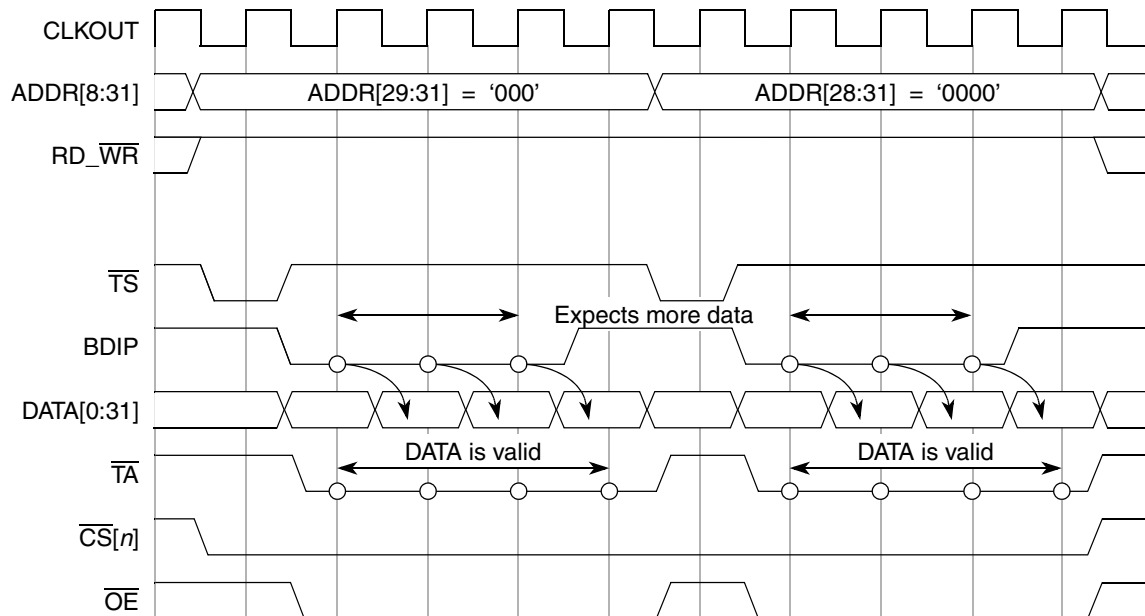

Figure 12-29. 32-Byte Read with Back-to-Back 16-Byte Bursts to 32-bit Port, Zero Wait States

12.4.2.7 Size, Alignment, and Packaging on Transfers

Table 12-17 shows the allowed sizes that an internal or external master can request from the EBI. The behavior of the EBI for request sizes not shown below is undefined. No error signal is asserted for these erroneous cases.

Table 12-17. Transaction Sizes Supported by EBI

No. Bytes (Internal Master)	No. Bytes (External Master)
1	1
2	2
4	4
3 ¹	
8	
32	

¹ Some misaligned access cases may result in 3-byte writes. These cases are treated as power-of-2 sized requests by the EBI, using $\overline{WE}/\overline{BE}[0:3]$ to make sure only the appropriate 3 bytes get written.

Even though misaligned non-burst transfers from internal masters are supported, the EBI naturally aligns the accesses when it sends them out to the external bus, splitting them into multiple aligned accesses if necessary.

Natural alignment for the EBI means:

- Byte access can have any address.
- 16-bit access, address bit 31 must be 0.
- 32-bit access, address bits 30–31 must be 0.
- For burst accesses of any size, address bits 29–31 must be 0.

The EBI never generates a misaligned external access, so a multi-master system with two MCUs can never have a misaligned external access. In the erroneous case that an externally-initiated misaligned access does occur, the EBI errors the access (by asserting \overline{TEA} externally) and does not initiate the access on the internal bus.

The EBI requires that the portion of the data bus used for a transfer to/from a particular port size be fixed. A 32-bit port must reside on data bus bits 0–31, and a 16-bit port must reside on bits 0–15.

In the following figures and tables the following convention is adopted:

- The most significant byte of a 32-bit operand is OP0, and OP3 is the least significant byte.
- The two bytes of a 16-bit operand are OP0 (most significant) and OP1, or OP2 (most significant) and OP3, depending on the address of the access.
- The single byte of a byte-length operand is OP0, OP1, OP2, or OP3, depending on the address of the access.

The convention can be seen in [Figure 12-30](#).

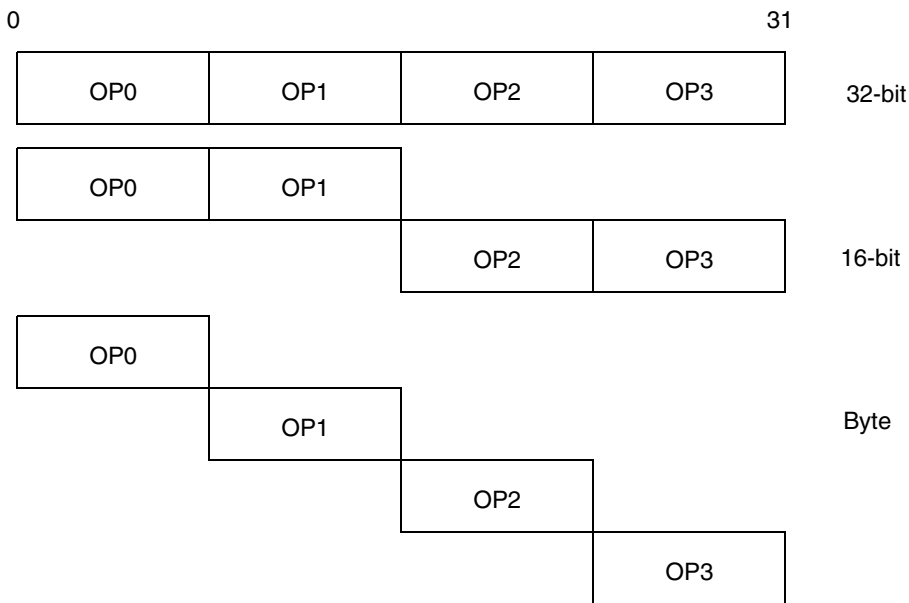

Figure 12-30. Internal Operand Representation

[Figure 12-31](#) shows the device connections on the DATA[0:31] bus.

Figure 12-31. Interface to Different Port Size Devices

Table 12-18 lists the bytes required on the data bus for read cycles. The bytes indicated as ‘—’ are not required during that read cycle.

Table 12-18. Data Bus Requirements for Read Cycles

Transfer Size	TSIZ[0:1] ¹	Address		32-Bit Port Size				16-Bit Port Size ²	
		A[30]	A[31]	D[0:7]	D[8:15]	D[16:23]	D[24:31]	D[0:7]	D[8:15]
Byte	01	0	0	OP0	—	—	—	OP0	—
	01	0	1	—	OP1	—	—	—	OP1
	01	1	0	—	—	OP2	—	OP2	—
	01	1	1	—	—	—	OP3	—	OP3
16-bit	10	0	0	OP0	OP1	—	—	OP0	OP1
	10	1	0	—	—	OP2	OP3	OP2	OP3
32-bit	00	0	0	OP0	OP1	OP2	OP3	OP0/OP2 ³	OP1/OP3

¹ TSIZ is not enabled on the MPC5565.

² Also applies when DBM = 1 for 16-bit data bus mode.

³ This case consists of two 16-bit external transactions, the first fetching OP0 and OP1, the second fetching OP2 and OP3.

Table 12-19 lists the patterns of the data transfer for write cycles when accesses are initiated by the MCU. The bytes indicated as ‘—’ are not driven during that write cycle.

Table 12-19. Data Bus Contents for Write Cycles

Transfer Size	TSIZ[0:1] ¹	Address		32-Bit Port Size				16-Bit Port Size ²	
		A[30]	A[31]	D[0:7]	D[8:15]	D[16:23]	D[24:31]	D[0:7]	D[8:15]
Byte	01	0	0	OP0	—	—	—	OP0	—
	01	0	1	OP1	OP1	—	—	—	OP1
	01	1	0	OP2	—	OP2	—	OP2	—
	01	1	1	OP3	OP3	—	OP3	—	OP3
16-bit	10	0	0	OP0	OP1	—	—	OP0	OP1
	10	1	0	OP2	OP3	OP2	OP3	OP2	OP3
32-bit	00	0	0	OP0	OP1	OP2	OP3	OP0/OP2 ³	OP1/OP3

¹ TSIZ is not enabled on the MPC5565.

² Also applies when DBM = 1 for 16-bit data bus mode.

³ This case consists of two 16-bit external transactions, the first writing OP0 and OP1, the second writing OP2 and OP3.

12.4.2.8 Arbitration

The MPC5565 does not have arbitration pins, so multi-master operation with arbitration is not supported. However, limited dual-MCU functionality is supported for the case of a Master/Slave system.

Refer to [Section 12.5.5, “Dual-MCU Operation with Reduced Pinout MCUs.”](#)

12.4.2.9 Termination Signals Protocol

The termination signals protocol was defined to avoid electrical contention on lines that can be driven by various sources. To do that, a slave must not drive signals associated with the data transfer until the address phase is completed and it recognizes the address as its own. The slave must disconnect from signals immediately after it acknowledges the cycle and not later than the termination of the next address phase cycle.

For EBI-mastered non-chip select accesses, the EBI requires assertion of \overline{TA} from an external device to signal that the bus cycle is complete. The EBI uses a latched version of \overline{TA} (1 cycle delayed) for these accesses to help make timing at high frequencies. This results in the EBI driving the address and control signals 1 cycle longer than required, as seen in [Figure 12-32](#). However, the DATA does not need to be held 1 cycle longer by the slave, because the EBI latches DATA every cycle during non-chip select accesses. During these accesses, the EBI does not drive the \overline{TA} signal, leaving it up to an external device (or weak internal pullup) to drive \overline{TA} .

For EBI-mastered chip select accesses, the EBI drives \overline{TA} the entire cycle, asserting according to internal wait state counters to terminate the cycle. During idle periods on the external bus, the EBI drives \overline{TA} negated as long as it is granted the bus; when it no longer owns the bus it lets go of \overline{TA} . When an external master does a transaction to internal address space, the EBI only drives \overline{TA} for the cycle it asserts \overline{TA} to return data and for 1 cycle afterwards to ensure fast negation.

If no device responds by asserting \overline{TA} within the programmed timeout period (BMT in EBI_BMCR) after the EBI initiates the bus cycle, the internal bus monitor (if enabled) asserts \overline{TEA} to terminate the cycle. An external device may also drive \overline{TEA} when it detects an error on an external transaction. \overline{TEA} assertion causes the cycle to terminate and the processor to enter exception processing for the error condition. To properly control termination of a bus cycle for a bus error with external circuitry, \overline{TEA} must be asserted at the same time or before (external) \overline{TA} is asserted. \overline{TEA} must be negated before the second rising edge after it was sampled asserted to avoid the detection of an error for the following bus cycle initiated. \overline{TEA} is only driven by the EBI during the cycle where the EBI is asserting \overline{TEA} and the cycle immediately following this assertion (for fast negation). During all other cycles, the EBI relies on a weak internal pullup to hold \overline{TEA} negated. This allows an external device to assert \overline{TEA} when it needs to indicate an error. External devices must follow the same protocol as the EBI, only driving \overline{TEA} during the assertion cycle and 1 cycle afterwards for negation.

NOTE

In the case where an external master asserts \overline{TEA} to timeout a transaction to an internal address on this MCU, the EBI has no way to terminate the transfer internally. Therefore, any subsequent \overline{TS} assertions by the external master are ignored by the EBI until the original transfer has completed internally and the EBI has returned to an idle state. The expectation is that the internal slaves will always respond with either valid data or an error indication within a reasonable period of time to avoid hanging the system.

When \overline{TEA} is asserted from an external source, the EBI uses a latched version of \overline{TEA} (1 cycle delayed) to help make timing at high frequencies. This means that for any accesses where the EBI drives \overline{TA} (chip select accesses and external master accesses to EBI), a \overline{TEA} assertion that occurs 1 cycle before or during the last \overline{TA} of the access could be ignored by the EBI, since it will have completed the access internally before it detects the latched \overline{TEA} assertion. This means that non-burst chip select accesses with no wait states ($SCY = 0$) cannot be reliably terminated by external \overline{TEA} . If external error termination is required for such a device, the EBI must be configured for $SCY \geq 1$.

NOTE

For the cases discussed above where \overline{TEA} could be ignored, this is not guaranteed. For some small access cases (which always use chip select and internally-driven \overline{TA}), a \overline{TEA} that occurs 1 cycle before or during the \overline{TA} cycle or for $SCY = 0$ may in fact lead to terminating the cycle with error. However, proper error termination is not guaranteed for these cases, so \overline{TEA} must always be asserted at least 2 cycles before an internally-driven \overline{TA} cycle for proper error termination.

External \overline{TEA} assertion that occurs during the same cycle that \overline{TS} is asserted by the EBI is always treated as an error (terminating the access) regardless of SCY .

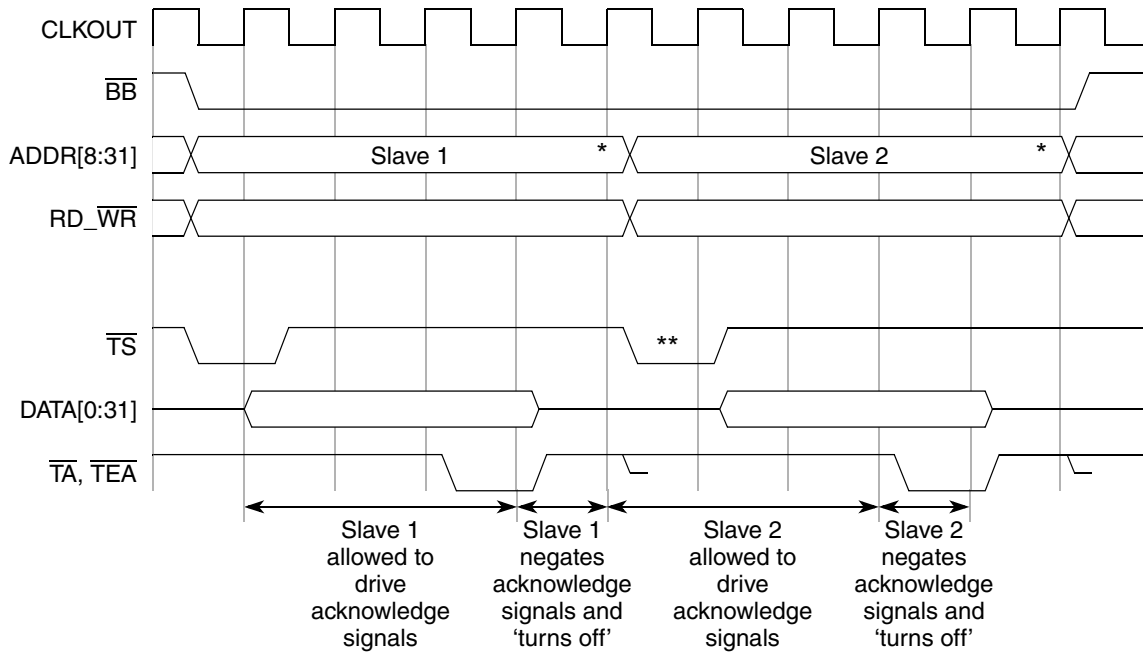

Table 12-20 summarizes how the EBI recognizes the termination signals provided from an external device.

Table 12-20. Termination Signals Protocol

TEA^1	TA^1	Action
Negated	Negated	No termination
Asserted	–	Transfer error termination
Negated	Asserted	Normal transfer termination

¹ Latched version (1 cycle delayed) used for externally driven \overline{TEA} and \overline{TA} .

Figure 12-32 shows an example of the termination signals protocol for back-to-back reads to two different slave devices who properly take turns driving the termination signals. This assumes a system using slave devices that drive termination signals.

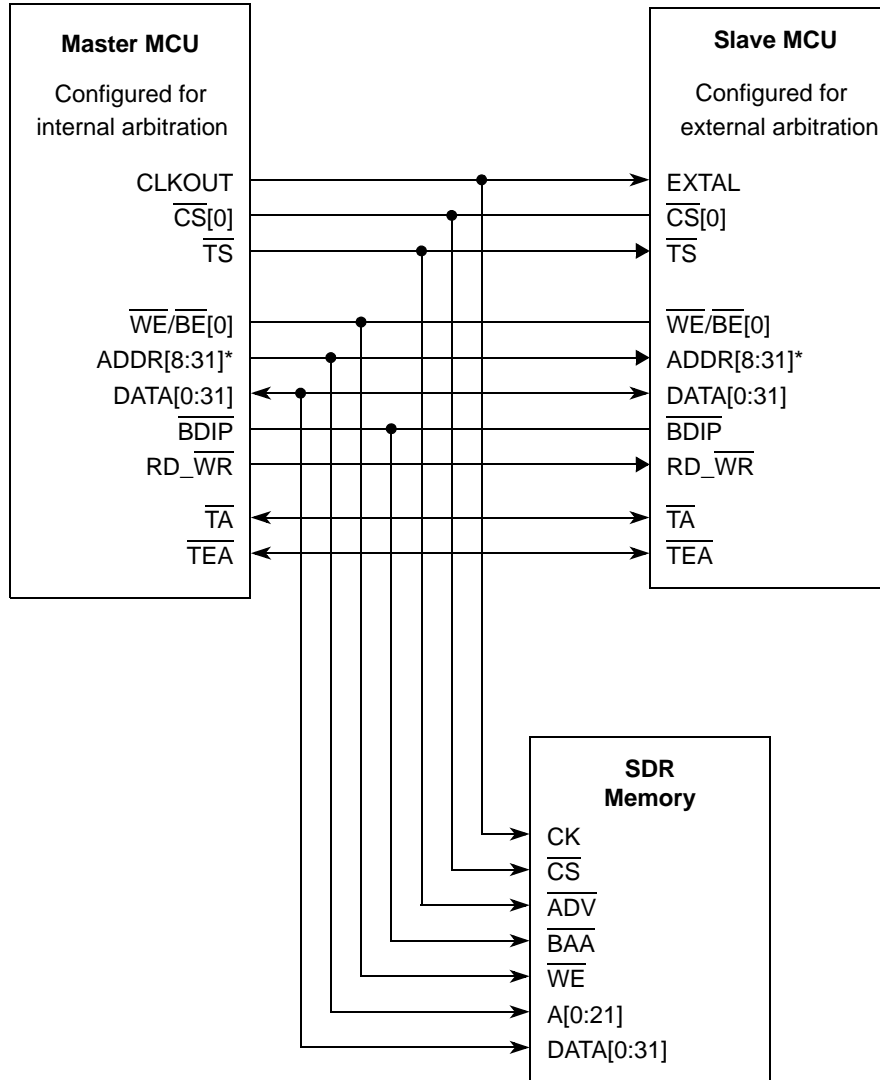

* The EBI drives address and control signals an extra cycle because it uses a latched version of \overline{TA} (1 cycle delayed) to terminate the cycle. An external master is not required to do this.

** This is the earliest that the EBI can start another transfer, in the case of continuing a set of small accesses. For all other cases, an extra cycle is needed before the EBI can start another \overline{TS} .

Figure 12-32. Termination Signals Protocol Timing Diagram

12.4.2.10 Bus Operation in External Master Mode

External master mode enables an external master to access the internal address space of the MCU. Figure 12-33 shows how to connect an MCU to an external master (a second MCU) and a shared SDR memory to operate in external master mode. Limited support for external master accesses (master/slave systems only) is available in the MPC5565, refer to Section 12.5.5, “Dual-MCU Operation with Reduced Pinout MCUs.”

* Only ADDR[8:29] are connected to the 32-bit SDR memory.

Figure 12-33. MCU Connected to External Master and SDR Memory

When the external master requires external bus accesses, it takes ownership on the external bus, and the direction of most of the bus signals is inverted, relative to its direction when the MCU owns the bus.

Most of the bidirectional signals shown in Figure 12-33 are only driven by the EBI when the EBI owns the external bus. The only exceptions are the \overline{TA} and \overline{TEA} signals (described in Section 12.4.2.9, “Termination

Signals Protocol”) and the DATA bus, which are driven by the EBI for external master reads to internal address space. As long as the external master device follows the same protocol for driving signals as this EBI, there is no need to use the open drain mode of the pads configuration module for any EBI pins.

The Power Architecture storage reservation protocol is not supported by the EBI. Coherency between multiple masters must be maintained via software techniques, such as event passing.

The EBI does not provide memory controller services to an external master that accesses shared external memories. Each master must properly configure its own memory controller and drive its own chip selects when sharing a memory between two masters.

The EBI does not support burst accesses from an external master; only single accesses of 8, 16, or 32 bits can be performed.¹

12.4.2.10.1 Address Decoding for External Master Accesses

The EBI allows external masters to access internal address space when the EBI is configured for external master mode. The external address is compared for any external master access, to determine if EBI operation is required. Because only 24 address bits are available on the external bus, special decoding logic is required to allow an external master to access on-chip locations whose upper 8 address bits are non-zero. This is done by using the upper 4 external address bits (ADDR[8:11]) as a code to determine whether the access is on-chip and if so, for which internal slave it is targeted.

NOTE

(External master accesses are not supported to the Calibration bus.)

The options for the address compare sequence are explained in the following bullets:

- External master access to another device — If ADDR[8] = 0, then the access is assumed to be to another device and is ignored by the EBI.
- External master access to valid internal slave — If ADDR[8] = 1, then ADDR[9:11] are checked versus a list of 3-bit codes to determine which internal slave to forward the access to. The upper 8 internal address bits are set appropriately by the EBI according to this 3-bit code, and internal address bits [8:11] are set appropriately to match the internal slave selected.
- External master access to invalid internal slave — If the 3-bit code does not match a valid internal slave, then the EBI responds with a bus error.

1. Except for the special case of a 32-bit non-chip select access in 16-bit data bus mode. Refer to [Section 12.4.2.11, “Non-Chip-Select Burst in 16-bit Data Bus Mode”](#).

Table 12-21 shows the possible 3-bit codes that are associated with various slaves in the MCU, as well as the resulting upper 12 address bits required to appropriately match up with the memory map of each internal slave.

Table 12-21. EBI Internal Slave Address Decoding

Internal Slave	External ADDR[8:11] ¹	Internal ADDR[0:7] ²	Internal ADDR[8:11] ³
(off-chip)	0b0xxx	—	—
Internal flash	0b10xx	0b0000_0000	0b00, ADDR[10:11]
Internal SRAM	0b1100	0b0100_0000	0b0000
Reserved	0b1101	0b0110_0000	0b0000
Bridge A peripherals	0b1110	0b1100_0011	0b1111
Bridge B peripherals	0b1111	0b1111_1111	0b1111

¹ Value on upper 4 bits of 24-bit external address bus ADDR[8:31]. ADDR[8] determines whether the access is on or off chip.

² Value on upper 8 bits of 32-bit internal address bus.

³ Value on bits 8:11 of 32-bit internal address bus.

12.4.2.10.2 Bus Transfers Initiated by an External Master

The external master gets ownership of the bus (refer to Section 12.4.2.8, “Arbitration”) and asserts \overline{TS} to initiate an external master access. The access is directed to the internal bus only if the input address matches to the internal address space. The access is terminated with either \overline{TA} or \overline{TEA} . If the access was successfully completed, the MCU asserts \overline{TA} , and the external master can proceed with another external master access, or relinquish the bus. If an address or data error was detected internally, the MCU asserts \overline{TEA} for one clock.

Figure 12-34 and Figure 12-35 illustrate the basic flow of read and write external master accesses.

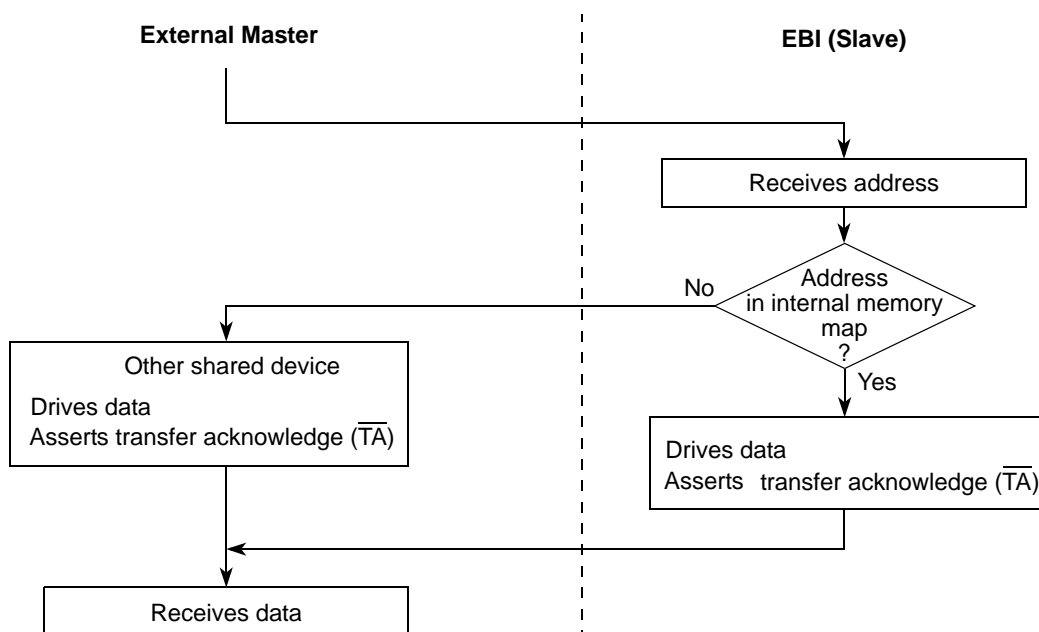

Figure 12-34. Basic Flow Diagram of an External Master Read Access (EARB = 1)

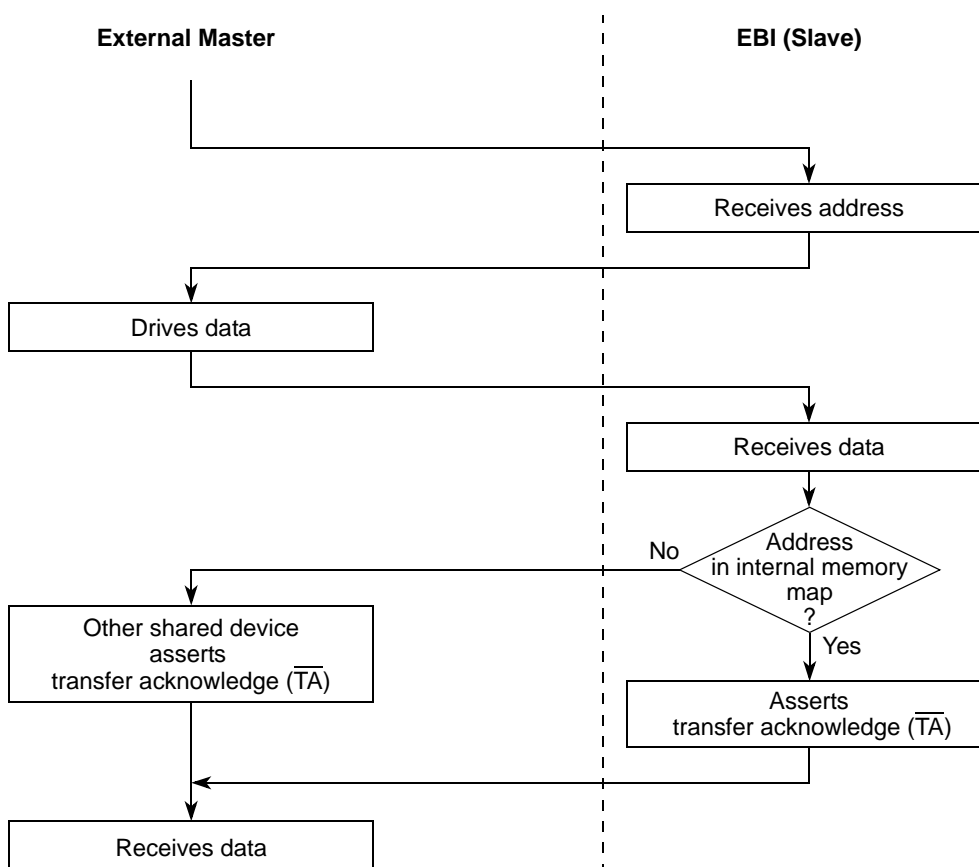

Figure 12-35. Basic Flow Diagram of an External Master Write Cycle (EARB = 1)

Figure 12-36 and Figure 12-37 describe read and write cycles from an external master accessing internal space in the MCU. The minimal latency for an external master access is three clock cycles. The actual latency of an external to internal cycle varies depending on which internal module is being accessed and how much internal bus traffic is going on at the time of the access.

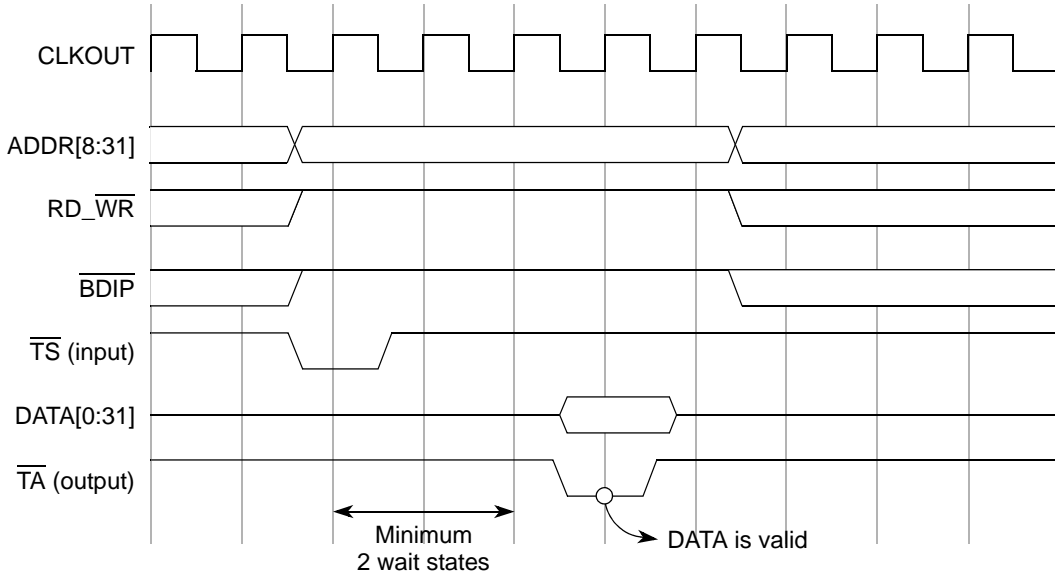

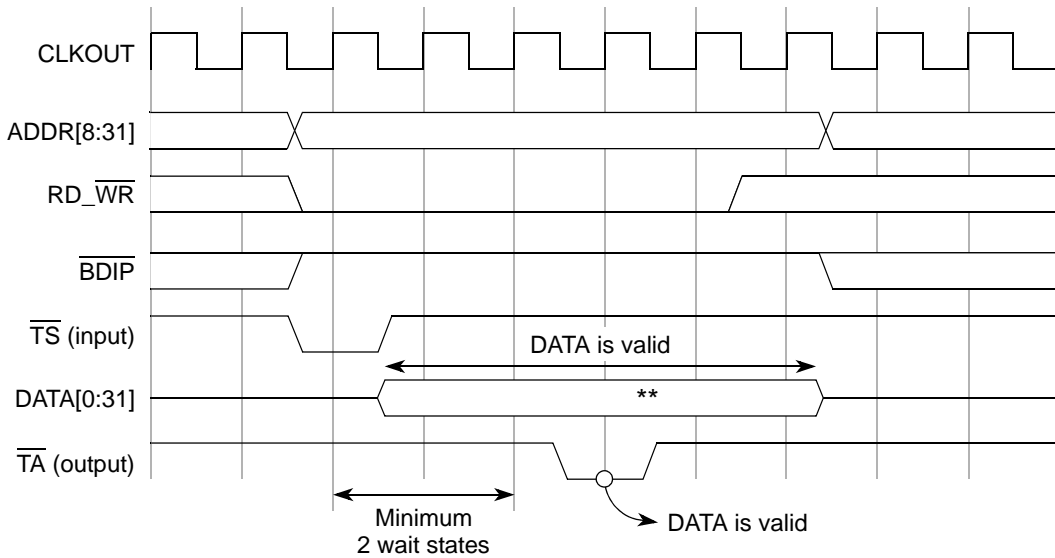

Figure 12-36. External Master Read from MCU

** If the external master is another MCU with this EBI, then DATA remains valid as shown due to use of latched TA internally. These extra data valid cycles (past TA) are not required by the slave EBI.

Figure 12-37. External Master Write to MCU

12.4.2.10.3 Bus Transfers Initiated by the EBI in External Master Mode

The flow and timing for EBI-mastered transactions in external master mode is identical to that described in earlier sections for single master mode. The following flow and timing diagrams show the basic single beat read case. The remaining cases (writes, bursts, etc.) can be observed in [Section 12.4.2.4, “Single-Beat Transfer,”](#) and [Section 12.4.2.5, “Burst Transfer.”](#)

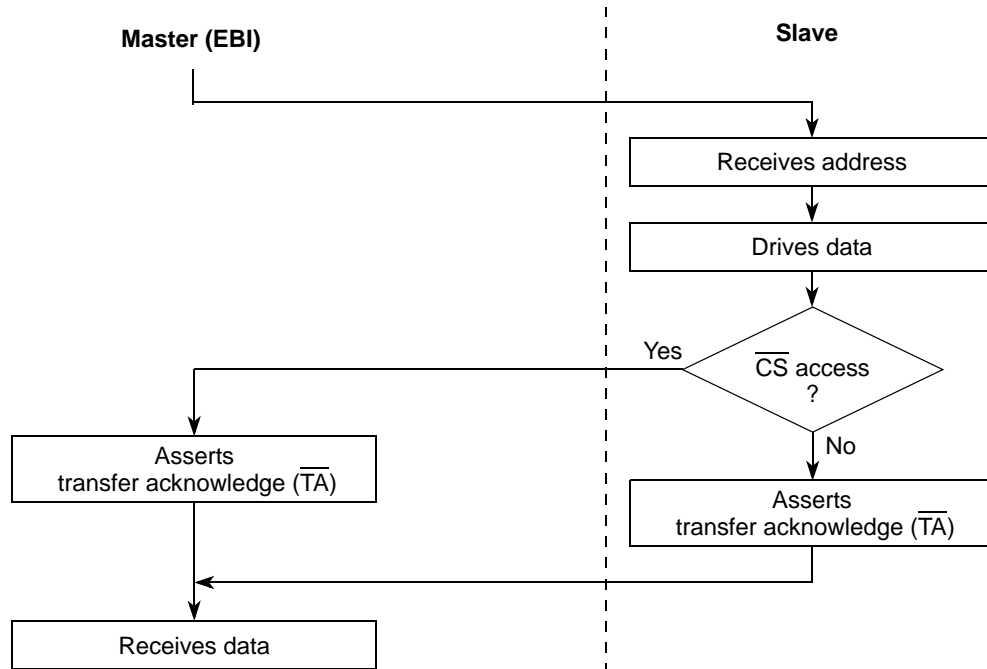

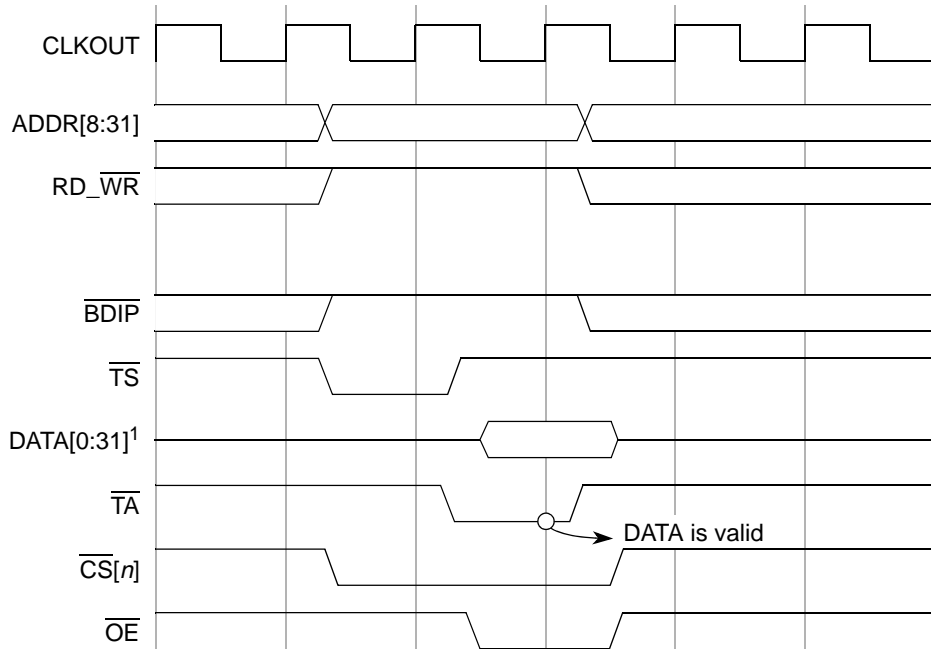

Figure 12-38. Basic Flow Diagram of an EBI Read Access in External Master Mode (EARB = 0)

¹ The 324 package only has DATA[0:15] for this device.

Figure 12-39. Single-Beat \overline{CS} Read Cycle in External Master Mode, Zero Wait States

12.4.2.11 Non-Chip-Select Burst in 16-bit Data Bus Mode

The timing diagrams in this section apply only to the special case of a non-chip select 32-bit access in 16-bit data bus mode. They specify the behavior for both the EBI-master and EBI-slave, as the external master is expected to be another MCU with this EBI.

For this case, a special two-beat burst protocol is used for reads and writes, so that the EBI-slave can internally generate one 32-bit read or write access (thus 32-bit coherent), as opposed to two separate 16-bit accesses.

[Figure 12-40](#) shows a 32-bit read from an external master in 16-bit data bus mode.

[Figure 12-41](#) shows a 32-bit write from an external master in 16-bit data bus mode.

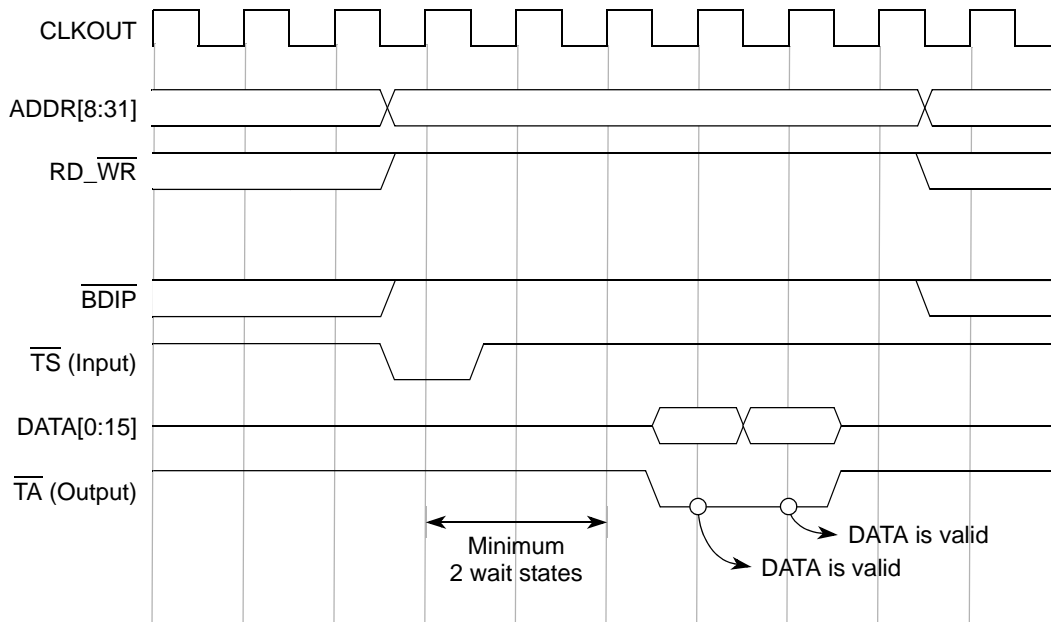

Figure 12-40. External Master 32-bit Read from MCU with DBM = 1

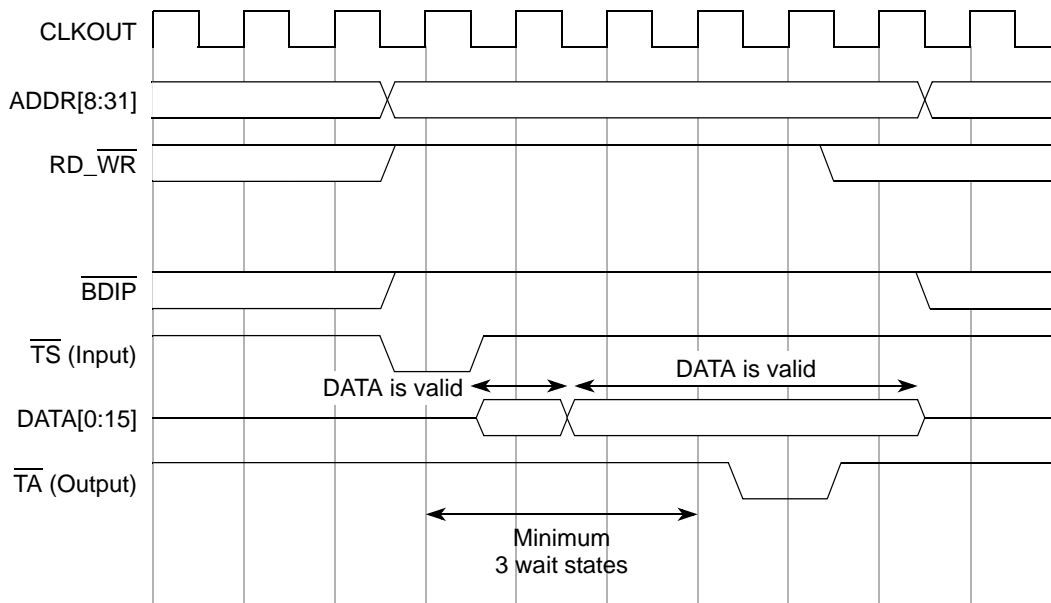

Figure 12-41. External Master 32-bit Write to MCU with DBM = 1

12.4.2.12 Calibration Bus Operation

The EBI has a second external bus, intended for calibration use. This bus consists of a second set of the same signals present on the primary external bus, except that arbitration, (and optionally other signals also) are excluded. Both busses are supported by the EBI by using the calibration chip selects to steer accesses to the calibration bus instead of to the primary external bus.

Because the calibration bus has no arbitration signals, the arbitration on the primary bus controls accesses on the calibration bus as well, and no external master accesses can be performed on the calibration bus. Accesses cannot be performed in parallel on both external busses. However, back-to-back accesses can switch from one bus to the other, as determined by the type of chip select each address matches.

The timing diagrams and protocol for the calibration bus are identical to those for the primary bus, except that some signals are not available on the calibration bus.

There is an inherent dead cycle between a calibration chip select access and a non-calibration access (chip select or non-chip select), just like the one between accesses to two different non-calibration chip selects (described in Section 12.4.2.4.3, “Back-to-Back Accesses”).

Figure 12-42 shows an example of a non-calibration chip select read access followed by a calibration chip select read access. This figure is identical to Figure 12-18, except the $\overline{CS}[y]$ is replaced by $CAL_CS[y]$. Timing for other cases on the calibration bus can similarly be derived from other figures in this document (by replacing \overline{CS} with CAL_CS).

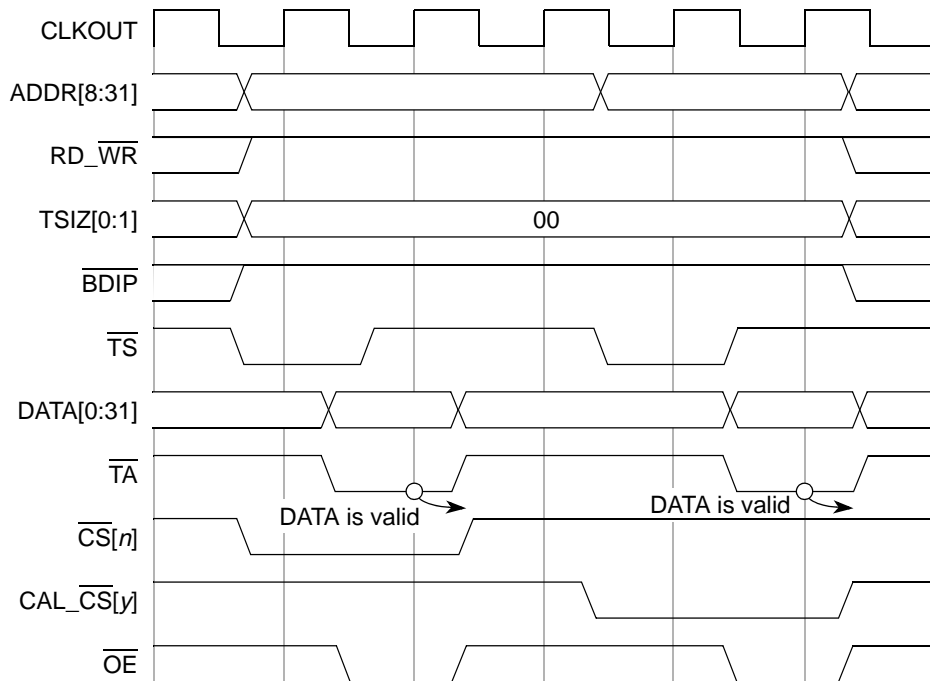

Figure 12-42. Back-to-Back 32-bit Reads to \overline{CS} , CAL_CS Banks

12.5 Initialization and Application Information

12.5.1 Booting from External Memory

The EBI block does not support booting directly to external memory (i.e. fetching the first instruction after reset externally). The MCU uses an internal boot assist module, which executes after each reset. The BAM code performs basic configuration of the EBI block, allowing for external boot if desired. Refer to [Section 15.1.3, “Modes of Operation,”](#) for detail information about the boot modes supported by the MCU; booting is not possible from external memory on the calibration bus.

If code in external memory needs to write EBI registers, this must be done in a way that avoids modifying EBI registers while external accesses are being performed, such as the following method:

- Copy the code that is doing the register writes (plus a return branch) to internal SRAM
- Branch to internal SRAM to run this code, ending with a branch back to external flash

12.5.2 Running with SDR (Single Data Rate) Burst Memories

This includes FLASH and external SRAM memories with a compatible burst interface. $\overline{\text{BDIP}}$ is required only for some SDR memories. [Figure 12-40](#) shows a block diagram of an MCU connected to a 32-bit SDR burst memory.

* Connection depending on the type of memory.

** Flash memories typically use one WE signal as shown, RAMs use 2 or 4 (16-bit or 32-bit).

*** Not available on all devices, refer to the Signals chapter.

Figure 12-43. MCU Connected to SDR Burst Memory

Refer to [Figure 12-23](#) for an example of the timing of a typical burst read operation to an SDR burst memory. Refer to [Figure 12-14](#) for an example of the timing of a typical single write operation to SDR memory.

12.5.3 Running with Asynchronous Memories

The EBI also supports asynchronous memories. In this case, the CLKOUT, \overline{TS} , and \overline{BDIP} pins are not used by the memory and bursting is not supported. However, the EBI still drives these outputs, and always drives and latches all signals at positive edge CLKOUT (i.e., there is no asynchronous mode for the EBI). The data timing is controlled by setting the SCY bits in the appropriate option register to the proper number of wait states to work with the access time of the asynchronous memory, just as done for a synchronous memory.

12.5.3.1 Example Wait State Calculation

This example applies to any chip select memory, synchronous or asynchronous.

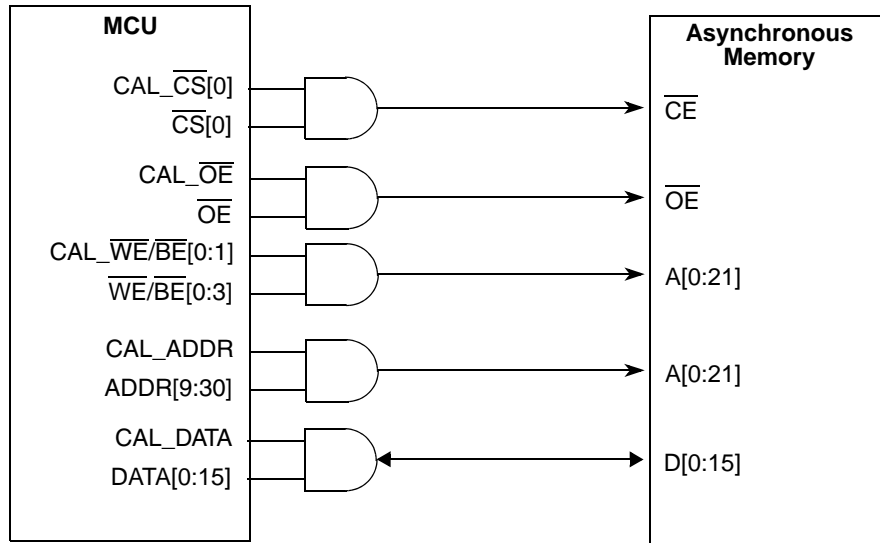

As an example, say we have a memory with 50 ns access time, and we are running the external bus at 66 MHz (CLKOUT period: 15.2 ns). When the input data specification for the MCU is 4 ns:

$$\begin{aligned} \text{Number of wait states} &= (\text{access time}) / (\text{CLKOUT period}) + (0 \text{ or } 1) \text{ (depending on setup time)} \\ 50/15.2 &= 3 \text{ with } 4.4 \text{ ns remaining (so we need at least three wait states, now check setup time)} \\ 15.2 - 4.4 &= 10.8 \text{ ns (this is the achieved input data setup time)} \end{aligned}$$

Because actual input setup (10.8 ns) is greater than the input setup specification (4.0 ns), three wait states is sufficient. If the input setup is less than 4.0 ns, use four wait states.

12.5.3.2 Timing and Connections for Asynchronous Memories

The connections to an asynchronous memory are the same as for a synchronous memory, except that the CLKOUT, \overline{TS} , and \overline{BDIP} signals are not used. [Figure 12-44](#) shows a block diagram of an MCU connected to an asynchronous memory.

* Flash memories typically use one \overline{WE} signal as shown.

Note: On a 32-bit bus, RAM memories use all four $\overline{WE}/\overline{BE}[0:3]$. On a 16-bit bus, one RAM memory uses $\overline{WE}/\overline{BE}[0:1]$ and the other uses $\overline{WE}/\overline{BE}[2:3]$.

Figure 12-44. MCU Connected to Asynchronous Memory

Figure 12-45 shows a timing diagram of a read operation to a 16-bit asynchronous memory using three wait states.

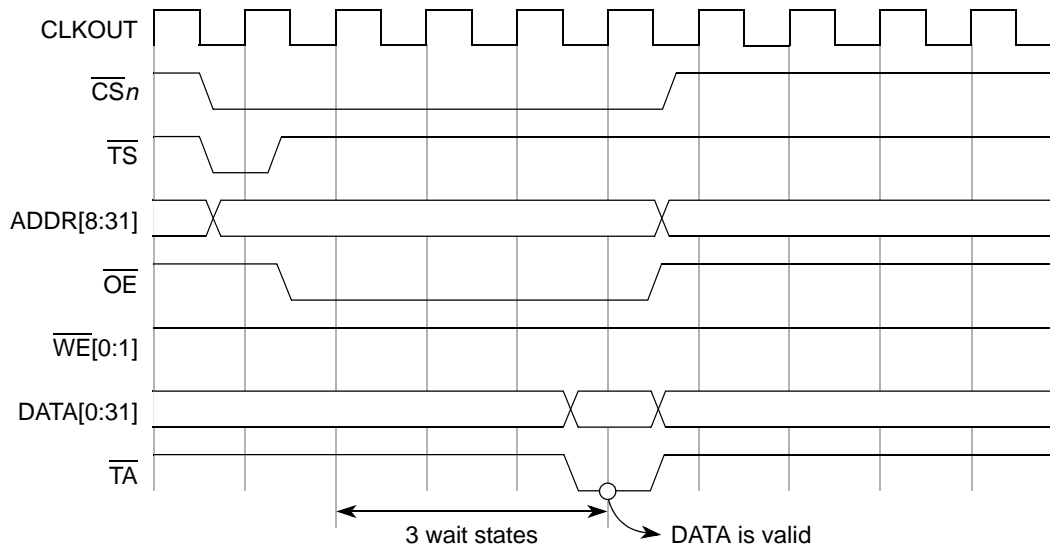

Figure 12-45. Read Operation to Asynchronous Memory, Three Initial Wait States

Figure 12-46 shows a timing diagram of a write operation to a 16-bit asynchronous memory using three wait states.

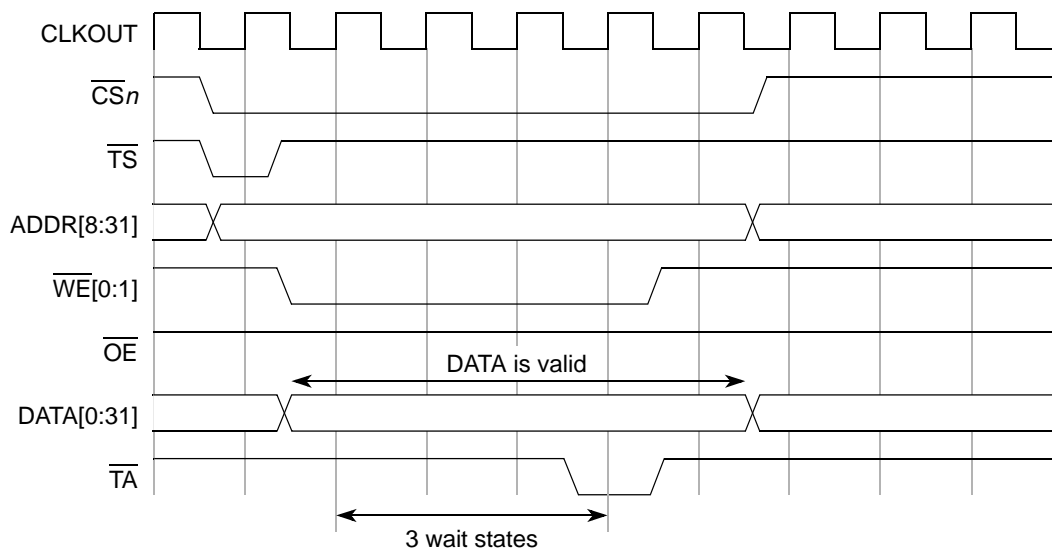

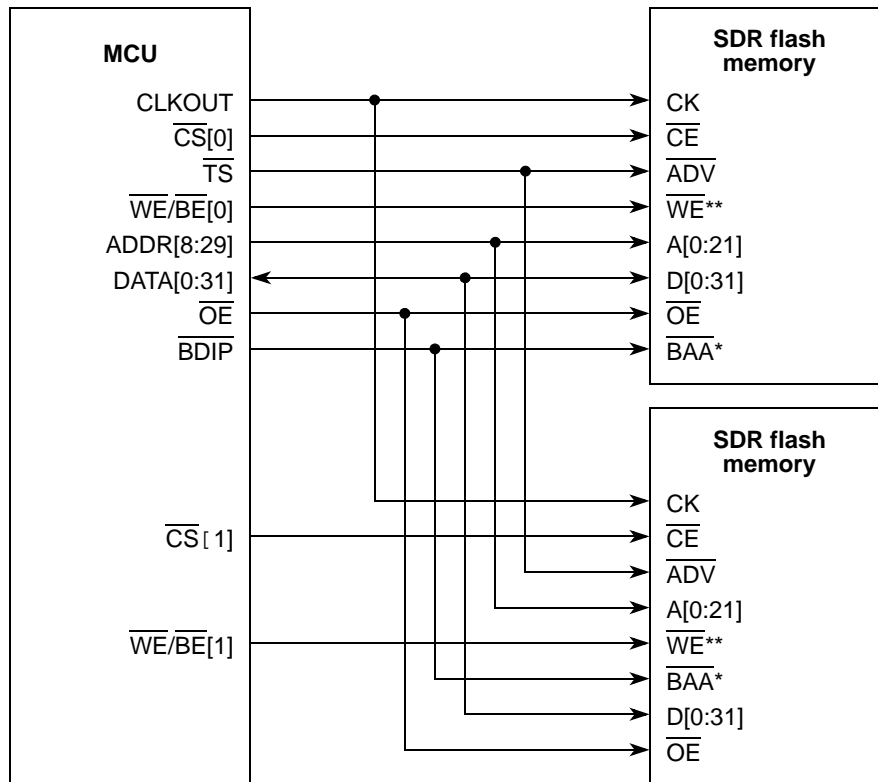

Figure 12-46. Write Operation to Asynchronous Memory, Three Initial Wait States

12.5.4 Connecting an MCU to Multiple Memories

The MCU can be connected to more than one memory at a time.

Figure 12-47 shows an example of how to connect two memories to one MCU.

* Connected depending on the memory used.

** Flash memories typically use one \overline{WE} signal as shown.

Note: On a 32-bit bus, RAM memories use all four $\overline{WE}/\overline{BE}[0:3]$. On a 16-bit bus, one RAM memory uses $\overline{WE}/\overline{BE}[0:1]$ and the other uses $\overline{WE}/\overline{BE}[2:3]$.

Figure 12-47. MCU Connected to Multiple Flash Memories

12.5.5 Dual-MCU Operation with Reduced Pinout MCUs

Not all the pins described in this document are available or connected in all the MPC5500 packages. Reduced pins are the DATA[16:31], arbitration pins (\overline{BB} , \overline{BG} , \overline{BR}), \overline{TEA} , and TSIZ[0:1] pins. This section describes how to configure dual-MCU systems for packages with reduced pin counts. More than one section can apply if the pins are not present on one or both MCUs.

12.5.5.1 Connecting 16-bit MCU to 32-bit MCU (Master/Master or Master/Slave)

This scenario is straightforward. Simply connect DATA[0:15] between both MCUs, and configure both for 16-bit data bus mode operation (DBM = 1 in EBI_MCR). This configuration does not support 32-bit external memories.

12.5.5.2 Arbitration with No Arb Pins (Master/Slave only)

Without arbitration pins, a dual-master system is impossible, because there is no way for the two masters to take turns driving the external bus without conflicts. However, a master/slave system is possible, as described below.

To implement a master/slave system with an MCU that has no arbitration pins (for example, in the MPC5565 that has no \overline{BB} , \overline{BG} , \overline{BR}), the user must configure the master MCU for internal arbitration ($EARB = 0$ in EBI_MCR) and the slave MCU for external arbitration ($EARB = 1$). Internally on an MCU with no arbitration pins, the external signals to the EBI will be tied negated. This means that the slave MCU will never receive bus grant asserted, so it will never attempt to start an access on the external bus. The master MCU will never receive bus request or bus busy asserted, so it will maintain ownership of the bus without any arbitration delays. In the erroneous case that the slave MCU executes internal code that attempts to access external address space, that access will never get external and will eventually time-out in the slave MCU.

12.5.5.3 Transfer Size with No TSIZ Pins (Master/Master or Master/Slave)

Because reduced pinout MCUs have no TSIZ pins to communicate transfer size from master MCU to slave MCU, the internal SIZE field of the EBI_MCR must be used on the slave MCU (by setting $SIZEN = 1$ in slave's EBI_MCR). Anytime the master MCU needs to read or write the slave MCU with a different transfer size than the current value of the slave's SIZE field, the master MCU must first write the slave's SIZE field with the correct size for the subsequent transaction.

12.5.5.4 No Transfer Acknowledge (\overline{TA}) Pin

If an MCU has no \overline{TA} pin available, this restricts the MCU to chip select accesses only. Non-chip select accesses have no way for the EBI to know which cycle to latch the data. The EBI has no built-in protection to prevent non-chip select accesses in this scenario; it is up to the user to make certain they set up chip selects and external memories correctly to ensure all external accesses fall in a valid chip select region.

12.5.5.5 No Transfer Error (\overline{TEA}) Pin

If an MCU has no \overline{TEA} pin available, this eliminates the feature of terminating an access with \overline{TEA} . This means if an access times out in the EBI bus monitor, the EBI (master) will still terminate the access early, but there will be no external visibility of this termination, so the slave device might end up driving data much later, when a subsequent access is already underway. Therefore, the EBI bus monitor should be disabled when no \overline{TEA} pin exists.

12.5.5.6 No Burst Data in Progress (\overline{BDIP}) Pin

If an MCU has no \overline{BDIP} pin available, this eliminates burst support only if the burstable memory being used requires \overline{BDIP} to burst. Many external memories use a self-timed configurable burst mechanism that does not require a dynamic burst indicator. Check the applicable external memory specification to see if \overline{BDIP} is required in your system.

12.5.6 Summary of Differences from MPC5xx

The following summary lists the significant differences between this EBI used in the MPC5xxx and that of the MPC5xx parts:

- SETA feature is no longer available: chip select devices cannot use external \overline{TA} , instead must use wait state configuration.
- No memory controller support for external masters: must configure each master in multi-master system to drive its own chip selects
- Changes in bit fields:
 - Removed these variable timing attributes from option register: CSNT, ACS, TRLX, EHTR
 - Removed LBDIP base register bit, now late \overline{BDIP} assertion is default behavior
 - Modified TSIZ[0:1] functionality to only indicate size of current transfer, not give information on ensuing transfers that may be part of the same atomic sequence
 - The BL field of the base register has inverted logic from the MPC56x devices (0 = eight-beat burst on the MPC5xxx, 1 = eight-beat burst on the MPC56x)
- Removed reservation support on external bus
- Removed address type (AT), write-protect (WP), and dual-mapping features because these functions can be replicated by memory management unit (MMU) in e200z6 core
- Removed support for 8-bit ports
- Removed boot chip select operation: on-chip boot assist module (BAM) handles boot (and configuration of EBI registers)
- Open drain mode and pullup resistors no longer required for multi-master systems, extra cycle needed to switch between masters
- Modified arbitration protocol to require extra cycles when switching between masters
- Added support for 32-bit coherent read and write non-chip select accesses in 16-bit data bus mode
- Misaligned accesses are not supported
- Calibration features implemented by three calibration chip selects
- Removed support for 3-master systems
- Address decoding for external master accesses uses 4-bit code to determine internal slave instead of straight address decode

12.6 Document Revision History

Table 22. Changes Between MPC5565RM Revisions 0.1 and 1

<p>Added: During a calibration bus access, the non-calibration bus signals (other than DATA) are held in a negated state, with the exception of RD_WR and ADDR, which reflect the same values shown on the calibration version of those signals. This is harmless because TS and CS are held negated on the non-calibration bus during calibration accesses, so no transfer takes place on the non-calibration bus. DATA is not driven by the EBI during calibration accesses.</p> <p>During a non-calibration bus access, the calibration bus signals (other than CAL_DATA) are held in a negated state. CAL_DATA is not driven during non-calibration accesses.</p>
<p>Added corrected “Read After Write to the Same CS Bank” figure, and added the note: “In some cases, CS remains asserted during this dead cycle, such as the cases of back-to-back writes or read-after-write to the same chip-select. See Figure 12-20 and Figure 12-21.</p>
<p>In Table 12.4.2.3 changed:</p> <ul style="list-style-type: none"> From: “To facilitate asynchronous write support, the EBI keeps driving valid write data on the data bus until 1 clock after the rising edge where RD_WR and WE are negated (for chip select accesses only).” To: “To facilitate asynchronous write support, the EBI keeps driving valid write data on the data bus until 1 clock after the rising edge where RD_WR (and WE for chip select accesses) are negated.
<p>Figure 12-2 added the Calibration signals.</p>
<p>Section 12.4.1.9, “Port Size Configuration per Calibration Chip Select (16 Bits): Conditionalized for 496 assembly only.</p>
<p>Section 12.2.1.13, “Transfer Size 0 through 1 (TSIZ[0:1]): Added: Because the MPC5565 does not have transfer size pins (TSIZ[0:1]), the SIZEN and SIZE fields of the EBI_MCR must be used for MCU-to-MCU transfers to indicate transfer size.</p>
<p>Section 12.3.1.3, “EBI Module Configuration Register (EBI_MCR) Added: Because the MPC5565 does not have transfer size pins (TSIZ[0:1]), the SIZEN and SIZE fields of the EBI_MCR must be used for MCU-to-MCU transfers to indicate transfer size.</p>

Table 22. Changes Between MPC5565RM Revisions 0.1 and 1 (continued)

<p>Added text to clarify the differences in the 324 package limitations and the device design:</p> <ul style="list-style-type: none"> Section 12.1.1, “Block Diagram” Added the following sentence to the first note in this section: The last two columns in for a list of available signals on the 324 package and the VertiCal assembly. The VertiCal assembly has ball connections for all the <i>available</i> signals on the device. <p>Added the following introductory sentence for a new table Table 12-1. The 324 package has a limited number of balls which affects the following EBI and calibration signals: Added Table 12-1.</p> <ul style="list-style-type: none"> Figure 12-1 <i>MPC5565 EBI Connections</i>: Added the following footnotes: <ol style="list-style-type: none"> Although the MPC5565 is designed to support a 32-bit EBI, not all pins are available on the 324 package. Refer to Table 12-1 for a description of the differences between the device design and package pinouts. The MPC5565 calibration bus and calibration signals are only available on the VertiCal assembly. Table 12-2 <i>Address Bus Sizes in the MPC5565</i>: Changed footnote 3 to read: <ol style="list-style-type: none"> The calibration feature is only available using the VertiCal assembly. The default calibration address bus is 19 bits muxed with CAL_ADDR[12:30]. However, it can be configured to use CAL_ADDR[10:11] of the muxed signals CAL_CS[2:3]_CAL_ADDR[10:11] to increase the calibration bus size to the maximum allowable width on this device of 21 bits. Table 12-3 <i>Data Bus Sizes in the MPC5565</i>: Added footnotes 1 and 2: <ol style="list-style-type: none"> Although the device is designed to support a 32-bit EBI data bus, the 324 package only supplies 16 balls for the EBI data bus (DATA[0:15]). The calibration feature is only available using the VertiCal assembly. Although the device is designed to support calibration, the 324 package does not provide balls for this feature. Section 12.1.4.2, “External Master Mode Changed the conditional text settings. Table 12-4 <i>Signal Properties</i>: Added and or changed the following footnotes: <ol style="list-style-type: none"> The 324 package does not support all the muxed signals in the device design. Refer to Table 12-1 for a description of the differences between the device design and the 324 package limitations. All EBI and calibration signals designed for this device are available on the VertiCal assembly. ADDR[8:11] signals are muxed as alternate signals with the chip select $\overline{CS}[0:3]$ and GPIO[0:3] signals. ADDR[8:11] are also available as primary signals in the device design muxed with GPIO[4:7], however ADDR[8:11]_GPIO[4:7] are not available in 324 package. Refer to Table 12-1 for more information. The 324 package does not have balls for the calibration bus signals; only the VertiCal assembly currently supports the calibration bus for this device. Section 12.2.1, “Detailed Signal Descriptions”: Added the following sentence: Refer to Table 12-1 for a description of the differences between the device design and the 324 package limitations.
<ul style="list-style-type: none"> Section 12.2, “External Signal Description”: Moved the following text from this section to Section 12.2.1.15, “Calibration Signals”: DATA is not driven by the EBI during a calibration bus access. During a calibration bus access, the non-calibration bus signals (other than DATA) are held in a negated state, with the exception of RD\overline{WR} and ADDR, which reflect the same values shown on the calibration version of those signals. Because the \overline{TS} and \overline{CS} signals are held negated on the EBI (non-calibration bus) during calibration accesses, no transfer occurs on the EBI. <p>During a EBI bus access, the calibration bus signals (other than CAL_DATA) are held in a negated state. CAL_DATA is not driven during non-calibration accesses.</p> <ul style="list-style-type: none"> Attempted to reconcile the conditional text in Section 12.2.1, “Detailed Signal Descriptions” and all its subsections. Table 12-5 <i>Signal Function (f) According to EBI Mode Settings</i>: Added the following footnotes: <ol style="list-style-type: none"> These signals are muxed with the chip select (\overline{CS}) signals on this device. Use the pad configuration registers (PCR) in the system integration module (SIU) to configure the balls to use the address signals <i>or</i> chip select signals—not both. This device is designed to support a 32-bit EBI data bus (DATA[0:31]) and four write/byte enable signals ($\overline{WE}/\overline{BE}[0:3]$) on the VertiCal assembly. The 324 package provides a 16-bit EBI data bus (DATA[0:16]) and two write/byte enable signals ($\overline{WE}/\overline{BE}[0:1]$) only. Although the device design supports the \overline{TEA} signal, it is not available on the 324 package. The \overline{TEA} signal is available for this device on the VertiCal assembly only. The calibration signals for this device are available on the VertiCal assembly only.

Chapter 13

Flash Memory

13.1 Introduction

This section provides information about the flash bus interface unit (FBIU) and the flash memory block.

13.1.1 Block Diagram

Figure 13-1 shows a block diagram of the flash memory module. The FBIU is addressed through the system bus while the flash control and status registers are addressed through the slave (peripheral) bus.

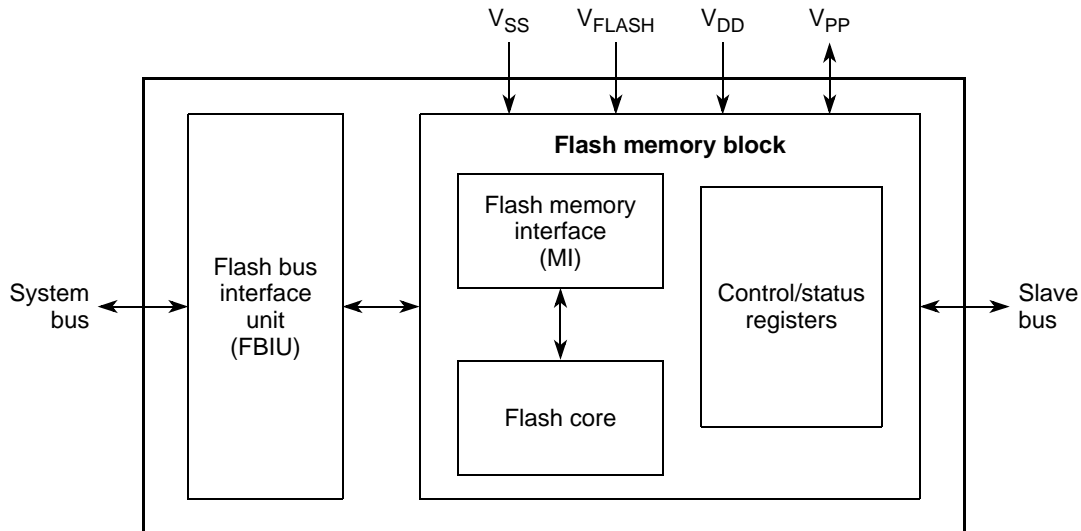

Figure 13-1. Flash System Block Diagram

13.1.2 Overview

The flash module serves as electrically programmable and erasable non-volatile memory (NVM) that is ideal for program and data storage for single-chip applications allowing for field reprogramming without requiring external programming voltage sources. The module is a solid-state silicon memory device consisting of blocks of single-transistor storage elements.

The device flash contains a flash bus interface unit (FBIU) and a flash memory array. The Flash BIU interfaces the system bus to a dedicated flash memory array controller. The FBIU supports a 64-bit data bus width at the system bus port, and a 256-bit read data interface from the flash memory array. If enabled, the Flash BIU contains a two-entry prefetch buffer, each entry containing 256 bits of data, and an associated controller that prefetches sequential lines of data from the flash array into the buffer. Prefetch

Flash Memory

buffer hits support zero-wait responses. Normal flash array accesses (i.e. those accesses that do not hit in the prefetch buffers) are registered in the FBIU and are forwarded to the system bus on the following cycle, incurring at least three wait states (depending on the frequency), with additional wait states being determined by FLASH_BUICR[RWSC] (refer to [Table 13-13](#)).

Prefetch operations can be automatically controlled, and can be restricted to servicing a single bus master. Prefetches can also be restricted to being triggered for instruction or data accesses.

The flash memory block is arranged as two functional units, the first being the flash core. The flash core is composed of arrayed non-volatile storage elements, sense amplifiers, row selects, column selects, charge pumps, ECC logic and redundancy logic. The arrayed storage elements in the flash core are subdivided into physically separate units referred to as blocks.

The second functional unit of flash memory is the memory interface (MI). The MI contains the registers and logic that control the operation of the flash core. The MI is also the interface between the flash module and the FBIU. The FBIU connects the MCU system bus to the flash module, and provides all system level customization and configuration functionality.

The flash array has three address spaces. Low address space (LAS) is 256-KB in size. Mid address space (MAS) is also 256-KB in size. High address space (HAS) is 1.5 MB in size. Total address space is 2.0 MB.

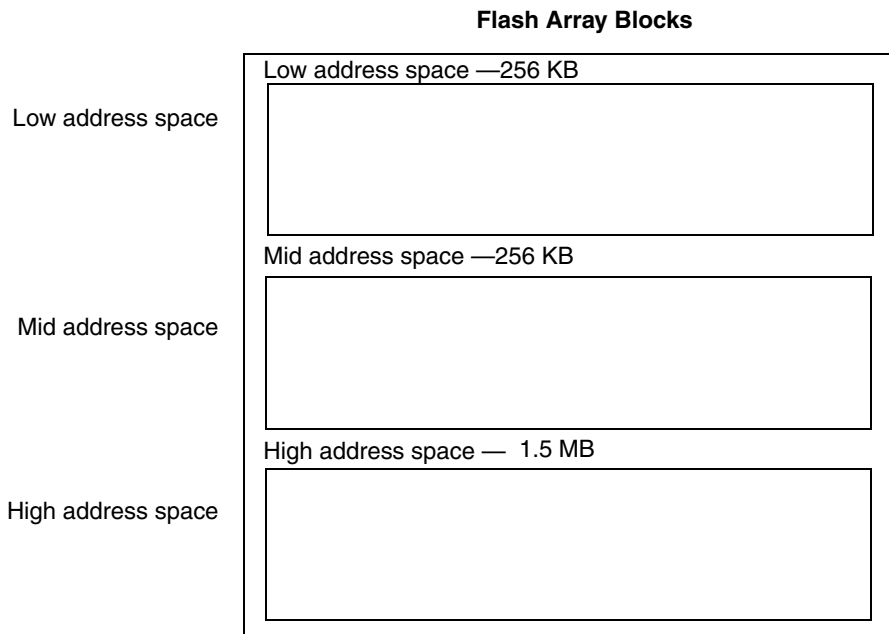

Figure 13-2. Flash Array Diagram

13.1.3 Features

The following list summarizes the key features of the FBIU:

- The FBIU system bus interface supports a 64-bit data bus. Byte, halfword, word, and doubleword reads are supported. Only aligned word and doubleword writes are supported.
- The FBIU provides configurable read buffering and line prefetch support. Two line read buffers (each 256 bits wide) and a prefetch controller are used to support single-cycle read responses for hits in the buffers.
- The FBIU provides hardware and software configurable read and write access protections on a per-master basis.
- The FBIU interface to the flash array controller is pipelined with a depth of 1.
- The FBIU allows configurable access timing.
- The FBIU provides multiple-mapping support and mapping-based block access timing (0–31 additional cycles) allowing use for emulation of other memory types.

The flash memory array has the following features:

- Software programmable block program/erase restriction control for low, mid, and high address spaces.
- Erase of selected blocks.
- ECC with single-bit correction, double-bit detection.
- Page program size of 256 bits allows programming from one to four consecutive 64-bit doublewords within a page.
- Embedded hardware program and erase algorithm.
- Read while write with multiple partitions.
- Stop mode for low power stand-by.
- Erase suspend, program suspend, and erase-suspended program.
- Automotive flash that meets automotive endurance and reliability requirements. Shadow information is stored in a non-volatile shadow block.
- Independent program/erase of the shadow block.

13.1.4 Modes of Operation

13.1.4.1 User Mode

User mode is the default operating mode of the flash memory block. In this mode, you can read, write, program, and erase the flash. Refer to [Section 13.4.2, “Flash Memory Array: User Mode.”](#)

13.1.4.2 Stop Mode

In stop mode ($\text{FLASH_MCR}[\text{STOP}] = 1$), all DC current sources in the flash are disabled. Refer to [Section 13.4.3, “Flash Memory Array: Stop Mode.”](#)

13.2 External Signal Description

Table 13-1 shows a list of signals required for flash.

Table 13-1. Signal Properties

Name	Function	Reset State
V _{FLASH}	Flash read power supply	N/A
V _{PP}	Flash program/erase power supply	N/A

13.2.1 Voltage for Flash Only (V_{FLASH})

V_{FLASH} is a supply required for reads of the flash core. This voltage is specified as 3.3 V with a tolerance of ± 0.3 V.

13.2.2 Program and Erase Voltage for Flash Only (V_{PP})

V_{PP} is a supply required for program and erase of the flash core. This voltage is specified as 5 V with a tolerance of -0.5 V to +0.25 V during program and erase operations. V_{PP} is required at all times, even during normal reads of flash memory. During read operations, V_{PP} can be as high as 5.3 V and as low as 3.0V.

13.3 Memory Map/Register Description

The Flash BIU occupies a 512-MB portion of the address space. The actual flash array is multiply-mapped within this space.

The MCU's internal flash has a feature that allows the internal flash timing to be modified to emulate an external memory, hence the name, external emulation mode. The upper five address lines are used to provide additional timing control that allows the FBIU response timing on the system bus (which must be controlled to provide for timing emulation of alternate memory types). Refer to [Figure 13-3](#).

Figure 13-3. Flash BIU Address Scheme

This feature allows calibration parameters to be tested using an external memory; and then in production, the internal flash access timing is modified to match timing of the external memory. The access time of the internal flash is lengthened based on the address range being accessed. To access an area with a slower access time, the address is modified per [Table 13-2](#).

13.3.1 Flash Memory Map

Table 13-2 shows the flash array memory map and how it is mapped using byte addressing.

Base addresses for the device are the following:

- Shadow base address = 0x00FF_FC00
- Array base address = 0x0000_0000
- Control registers base address = 0xC3F8_8000

Table 13-2. Module Flash Array Memory Map

Byte Address	Type and Amount of Space Used	Access
Shadow base + 0x0000_0000– Shadow base + 0x0000_03FF	Shadow block space (1024 bytes)	User
Array base + 0x0000_0000– Array base + 0x0003_FFFF	Low address space (256 KB)	User
Array base + 0x0004_0000– Array base + 0x0007_FFFF	Mid address space (256 KB)	User
Array base + 0x0008_0000– Array base + 0x001F_FFFF	High address space (1.5 MB)	User

Table 13-3 shows how the array is partitioned into three address spaces — low, mid, and high — and into partitions and blocks.

Table 13-3. Flash Partitions

Address	Use	Block	Size	Partition
Array base + 0x0000_0000	Low address space	L0	16 KB	1
Array base + 0x0000_4000		L1	48 KB	
Array base + 0x0001_0000		L2	48 KB	
Array base + 0x0001_C000		L3	16 KB	
Array base + 0x0002_0000		L4	64 KB	
Array base + 0x0003_0000	L5	64 KB	2	
Array base + 0x0004_0000	Mid address space	M0	128 KB	3
Array base + 0x0006_0000		M1	128 KB	
Array base + 0x0008_0000	High address space	H0	128 KB	4
Array base + 0x000A_0000		H1	128 KB	
Array base + 0x000C_0000		H2	128 KB	5
Array base + 0x000E_0000		H3	128 KB	
Array base + 0x0010_0000		H4	128 KB	6
Array base + 0x0012_0000		H5	128 KB	
Array base + 0x0014_0000		H6	128 KB	7
Array base + 0x0016_0000		H7	128 KB	
Array base + 0x0018_0000		H8	128 KB	8
Array base + 0x001A_0000		H9	128 KB	
Array base + 0x001C_0000		H10	128 KB	9
Array base + 0x001E_0000	H11	128 KB		

Table 13-3. Flash Partitions (continued)

Address	Use	Block	Size	Partition
Array base + 0x00FF_FC00	Shadow block space	S	472 KB	All ¹
Array base + 0x00FF_FDD8	Flash shadow row, serial passcode		8 KB	
Array base + 0x00FF_FDE0	Flash shadow row, control word		4 KB	
Array base + 0x00FF_FDE4	General use		4 KB	
Array base + 0x00FF_FDE8	Flash shadow row, FLASH_LMLR reset configuration		4 KB	
Array base + 0x00FF_FDEC	General use		4 KB	
Array base + 0x00FF_FDF0	Flash shadow row, FLASH_HLR reset configuration		4 KB	
Array base + 0x00FF_FDF4	For general use		4 KB	
Array base + 0x00FF_FDF8	Flash Shadow Row, FLASH_SLMLR reset configuration		4 KB	
Array base + 0x00FF_FDFC–0x00FF_FFFF	For general use		516 KB	

¹ The shadow row does not support RWW. Refer to [Section 13.4.2.5, “Flash Shadow Block.”](#)

Table 13-4 shows the register set for the flash module.

Table 13-4. Module Register Memory Map

Byte Address	Register Name	Register Description	Bits
Register base + 0x0000	FLASH_MCR	Module configuration register	32
Register base + 0x0004	FLASH_LMLR	Low/mid address space block locking register	32
Register base + 0x0008	FLASH_HLR	High address space block locking register	32
Register base + 0x000C	FLASH_SLMLR	Secondary low/mid address space block locking register	32
Register base + 0x0010	FLASH_LMSR	Low/mid address space block select register	32
Register base + 0x0014	FLASH_HSR	High address space block select register	32
Register base + 0x0018	FLASH_AR	Address register	32
Register base + 0x001C	FLASH_BIUCR	Flash bus interface unit control register	32
Register base + 0x0020	FLASH_BIUAPR	Flash bus interface unit access protection register	32
Register base + 0x30 to Register base + 0x7FFF	—	Reserved	—

13.3.2 Register Descriptions

The flash registers are detailed in the following sections.

13.3.2.1 Module Configuration Register (FLASH_MCR)

A number of module configuration register (FLASH_MCR) bits are protected from a write while another bit or set of bits are in a specific state. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is discussed in [Section 13.3.2.1.1, “MCR Simultaneous Register Writes.”](#) The MCR is always available to be read except when the flash module is disabled.

Address: Base (0xC3F8_8000) + 0x0000

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 13-4. Module Configuration Register (FLASH_MCR)

Table 13-5. FLASH_MCR Field Descriptions

Field	Description
0–3	Reserved.
4–7 SIZE[0:3]	Array space size. Dependent upon the size of the flash module. SIZE is read only. 0111 Total array size is 2 MB
8	Reserved.
9–11 LAS[0:2]	Low address space. Corresponds to the configuration of the low address space. All possible values of LAS and the configuration to which each value corresponds are shown below. LAS is read only. 110 The LAS value of 110 provides two 16-KB blocks, two 48-KB blocks, and two 64-KB blocks.
12–14	Reserved.
15 MAS	Mid address space size. Corresponds to the configuration of the mid address space. MAS is read only. 0 Two 128-KB blocks are available

Table 13-5. FLASH_MCR Field Descriptions (continued)

Field	Description
16 EER	<p>ECC event error. Provides information on previous reads; if a double bit detection occurred, the EER bit is set to 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. This bit cannot be set by the application. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) were correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.</p> <p>0 Reads are occurring normally. 1 An ECC Error occurred during a previous read.</p> <p>Note: This bit can be set on speculative prefetches that cause double bit error detection. Therefore, use the ECSM[FNCE] flag for detecting non-correctable ECC errors in the flash instead of using FLASH_MCR[EER].</p>
17 RWE	<p>Read while write event error. Provides information on previous RWW reads. If a read while write error occurs, this bit is set to 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. This bit cannot be set to 1 by the user. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last reset, or clearing of RWE) were correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.</p> <p>0 Reads are occurring normally. 1 A read while write error occurred during a previous read.</p>
18–19	Reserved.
20 PEAS	<p>Program/erase access space. Indicates which space is valid for program and erase operations, either main array space or shadow space. PEAS is read only.</p> <p>0 Shadow address space is disabled for program/erase and main address space enabled 1 Shadow address space is enabled for program/erase and main address space disabled.</p>
21 DONE	<p>State machine status. Indicates if the flash module is performing a high voltage operation. DONE is set to a 1 on termination of the flash module reset and at the end of program and erase high voltage sequences.</p> <p>0 Flash is executing a high voltage operation. 1 Flash is not executing a high voltage operation.</p>
22 PEG	<p>Program/erase good. Indicates the completion status of the last flash program or erase sequence for which high voltage operations were initiated. The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the module is reset. PEG is read only.</p> <p>The value of PEG is valid only when PGM = 1 and/or ERS = 1 and after DONE has transitioned from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. The value in PEG is not valid after a 0 to 1 transition of DONE caused by PSUS or ESUS being set to logic 1. A diagram presenting PEG valid times is presented in Figure 13-5. If PGM and ERS are both 1 when DONE makes a qualifying 0 to 1 transition the value of PEG indicates the completion status of the PGM sequence. This happens in an erase-suspended program operation.</p> <p>0 Program or erase operation failed. 1 Program or erase operation successful.</p>
23–24	Reserved.
25 STOP	<p>Stop mode enabled. Puts the flash into stop mode. Changing the value in STOP from a 0 to a 1 places the flash module in stop mode. A 1 to 0 transition of STOP returns the flash module to normal operation. STOP can be written only when PGM and ERS are low. When STOP = 1, only the STOP bit in the MCR can be written. In STOP mode all address spaces, registers, and register bits are deactivated except for the FLASH_MCR[STOP] bit.</p> <p>0 Flash is not in stop mode; the read state is active. 1 Flash is in stop mode.</p>

Table 13-5. FLASH_MCR Field Descriptions (continued)

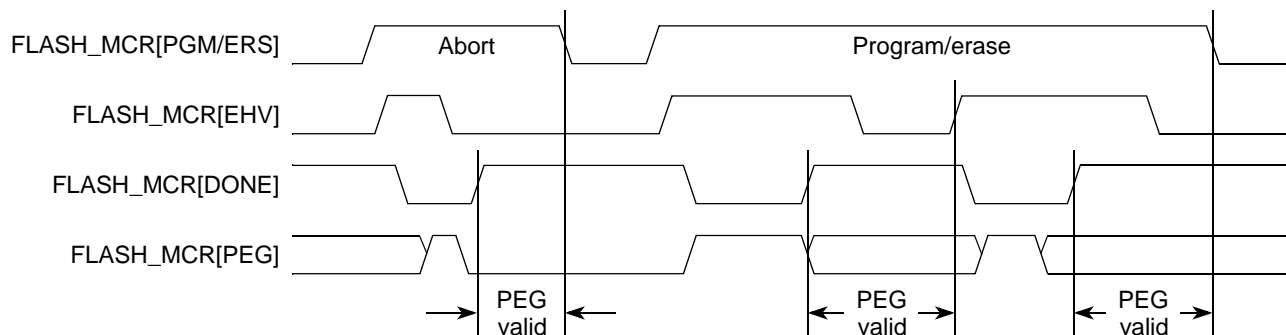

Field	Description
26	Reserved.
27 PGM	<p>Program. Used to set up flash for a program operation. A 0 to 1 transition of PGM initiates an flash program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set only under one of the following conditions:</p> <ul style="list-style-type: none"> • User mode read (STOP and ERS are low). • Erase suspend¹ (ERS and ESUS are 1) with EHV low. <p>PGM can be cleared by the user only when EHV are low and DONE is high. PGM is cleared on reset.</p> <p>0 Flash is not executing a program sequence. 1 Flash is executing a program sequence.</p>
28 PSUS	<p>Program suspend. Indicates the flash module is in program suspend or in the process of entering a suspend state. The flash module is in program suspend when PSUS = 1 and DONE = 1. PSUS can be set high only when PGM and EHV are high. A 0 to 1 transition of PSUS starts the sequence which sets DONE and places the flash in program suspend. PSUS can be cleared only when DONE and EHV are high. A 1 to 0 transition of PSUS with EHV = 1 starts the sequence which clears DONE and returns the flash module to program. The flash module cannot exit program suspend and clear DONE while EHV is low. PSUS is cleared on reset.</p> <p>0 Program sequence is not suspended. 1 Program sequence is suspended.</p>
29 ERS	<p>Erase. Used to set up flash for an erase operation. A 0 to 1 transition of ERS initiates an flash erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can be set only in a normal operating mode read (STOP and PGM are low). ERS can be cleared by the user only when ESUS and EHV are low and DONE is high. ERS is cleared on reset.</p> <p>0 Flash is not executing an erase sequence. 1 Flash is executing an erase sequence.</p>
30 ESUS	<p>Erase suspend. Indicates that the flash module is in erase suspend or in the process of entering a suspend state. The flash module is in erase suspend when ESUS = 1 and DONE = 1. ESUS can be set high only when ERS and EHV are high and PGM is low. A 0 to 1 transition of ESUS starts the sequence which sets DONE and places the flash in erase suspend. ESUS can be cleared only when DONE and EHV are high and PGM is low. A 1 to 0 transition of ESUS with EHV = 1 starts the sequence which clears DONE and returns the flash module to erase mode. The flash module cannot exit erase suspend and clear DONE while EHV is low. ESUS is cleared on reset.</p> <p>0 Erase sequence is not suspended. 1 Erase sequence is suspended.</p>

Table 13-5. FLASH_MCR Field Descriptions (continued)

Field	Description
31 EHV	<p>Enable high voltage. Enables the flash module for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after an interlock write to start a program/erase sequence. EHV can be set, initiating a program/erase, after an interlock write under one of the following conditions:</p> <ul style="list-style-type: none"> • Erase (ERS = 1, ESUS = 0). • Program (ERS = 0, ESUS = 0, PGM = 1, PSUS = 0). • Erase-suspended program (ERS = 1, ESUS = 1, PGM = 1, PSUS = 0). <p>If a program operation is to be initiated while an erase is suspended the user must clear EHV while in erase suspend before setting PGM.</p> <p>In normal operation, a 1 to 0 transition of EHV with DONE high, PSUS and ESUS low terminates the current program/erase high voltage operation.</p> <p>When an operation is aborted², there is a 1 to 0 transition of EHV with DONE low and the suspend bit for the current program/erase sequence low. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort.</p> <p>A suspended operation cannot be aborted. EHV can be written during suspend. EHV must be high for the flash to exit suspend. Do not write the EHV bit after a suspend bit is set high and before DONE has transitioned high. Do not set the EHV bit low after the current suspend bit is set low and before DONE has transitioned low.</p> <p>0 Flash is not enabled to perform a high voltage operation. 1 Flash is enabled to perform a high voltage operation.</p>

¹ In an erase-suspended program, programming flash locations in blocks which were being operated on in the erase can corrupt flash core data. Avoid this case due to reliability implications.

² Aborting a high voltage operation leaves the flash core addresses in an indeterminate data state. This can be recovered by executing an erase on the affected blocks.

Figure 13-5. PEG Valid Times

13.3.2.1.1 MCR Simultaneous Register Writes

A number of MCR bits are protected against write when another bit or set of bits is in a specific state. These write locks are covered on a bit by bit basis in [Section 13.3.2.1, “Module Configuration Register \(FLASH_MCR\).”](#) The write locks detailed in that section do not consider the effects of trying to write two or more bits simultaneously. The effects of writing bits simultaneously which would put the flash module in an illegal state are detailed here.

The flash does not allow the user to write bits simultaneously which would put the device into an illegal state. This is implemented through a priority mechanism among the bits. The bit changing priorities are detailed in [Table 13-6](#).

Table 13-6. MCR Bit Set/Clear Priority Levels

Priority Level	MCR Bits
1	STOP
2	ERS
3	PGM
4	EHV
5	ESUS, PSUS

If the user attempts to write two or more MCR bits simultaneously then only the bit with the highest priority level is written. Setting two bits with the same priority level is prevented by existing write locks and does not put the flash in an illegal state.

For example, setting FLASH_MCR[STOP] and FLASH_MCR[PGM] simultaneously results in only FLASH_MCR[STOP] being set. Attempting to clear FLASH_MCR[EHV] while setting FLASH_MCR[PSUS] results in FLASH_MCR[EHV] being cleared, while FLASH_MCR[PSUS] remains unaffected.

13.3.2.2 Low/Mid Address Space Block Locking Register (FLASH_LMLR)

The low and mid address block locking register provides a means to protect blocks from being modified. These bits along with bits in the secondary LMLOCK field (FLASH_SLMLR), determine if the block is locked from program or erase. An “OR” of FLASH_LMLR and FLASH_SLMLR determine the final lock status. Refer to [Section 13.3.2.4, “Secondary Low/Mid Address Space Block Locking Register \(FLASH_SLMLR\)”](#) for more information on FLASH_SLMLR.

NOTE

In the event that blocks are not present (due to configuration or total memory size), the LOCK bits defaults to locked, and are not writable. The reset value is always 1 (independent of the shadow block), and register writes have no effect.

¹ The reset value of these bits is determined by flash values in the shadow row. Erasing the array sets the reset value to 1.

Figure 13-6. Low/Mid Address Space Block Locking Register (FLASH_LMLR)

Table 13-7. FLASH_LMLR Field Descriptions

Field	Description
0 LME	<p>Low and mid address lock enable. Enables the locking register fields (SLOCK, MLOCK and LLOCK) to be set or cleared by register writes. This bit is a status bit only, and can not be written or cleared, and the reset value is 0. The method to set this bit is to write a password, and if the password matches, the LME bit is set to reflect the status of enabled, and is enabled until a reset operation occurs. For LME, the password 0xA1A1_1111 must be written to the FLASH_LMLR.</p> <p>0 Low and mid address locks are disabled, and cannot be modified. 1 Low and mid address locks are enabled and can be written.</p>
1–10	Reserved.
11 SLOCK	<p>Shadow lock. Locks the shadow row from programs and erases. The SLOCK bit is not writable if a high voltage operation is suspended.</p> <p>Upon reset, information from the shadow row is loaded into the SLOCK bit. The SLOCK bit can be written as a register. Reset causes the bits to go back to their shadow row value. The default value of the SLOCK bit (assuming the corresponding shadow row bit is erased) would be locked. SLOCK is not writable unless LME is high.</p> <p>0 Shadow row is available to receive program and erase pulses. 1 Shadow row is locked for program and erase.</p>
12–13	Reserved.
14–15 MLOCK[1:0]	<p>Mid address block lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. Likewise the lock register is not writable if a high voltage operation is suspended.</p> <p>Upon reset, information from the shadow row is loaded into the block registers. The LOCK bits can be written as a register. Reset causes the bits to go back to their shadow row value. The default value of the LOCK bits (assuming erased fuses) would be locked.</p> <p>In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to locked, and are not writable. The reset value always is 1 (independent of the shadow row), and register writes have no effect.</p> <p>MLOCK is not writable unless LME is high.</p>
16–25	Reserved
26–31 LLOCK[5:0]	<p>Low address block lock. These bits have the same description and attributes as MLOCK. As an example of how the LLOCK bits are used, if a configuration has sixteen 16-KB blocks in the low address space (MCR-LAS = 3'b011), the block residing at address array base + 0, corresponds to LLOCK0. The next 16-KB block corresponds to LLOCK1, and so on up to LLOCK15.</p>

13.3.2.3 High Address Space Block Locking Register (FLASH_HLR)

The high address space block locking register provides a means to protect blocks from being modified.

Address: Base (0xC3F8_8000) + 0x0008

Access: R/W

¹ The reset value of these bits is determined by flash values in the shadow row. An erased array causes the reset value to be 1.

Figure 13-7. High Address Space Block Locking Register (FLASH_HLR)

Table 13-8. FLASH_HLR Field Descriptions

Field	Description
0 HBE	High address lock enable. Enables the locking field (HLOCK) to be set or cleared by register writes. This bit is a status bit only, and cannot be written to or cleared, and the reset value is 0. The method to set this bit is to provide a password, and if the password matches, the HBE bit is set to reflect the status of enabled, and is enabled until a reset operation occurs. For HBE, the password 0xB2B2_2222 must be written to FLASH_HLR. 0 High address locks are disabled, and cannot be modified. 1 High address locks are enabled to be written.
1–19	Reserved.
20–31 HLOCK[11:0]	High address space block lock. Has the same characteristics as MLOCK. Refer to Section 13.3.2.2, “Low/Mid Address Space Block Locking Register (FLASH_LMLR)” for more information. The block numbering for High Address space starts with HLOCK[0] and continues until all blocks are accounted. HLOCK is not writable unless HBE is set. In the event that blocks are not present (due to configuration or total memory size), the HLOCK bits are default to locked, and are not writable.

13.3.2.4 Secondary Low/Mid Address Space Block Locking Register (FLASH_SLMLR)

The FLASH_SLMLR provides an alternative means to protect blocks from being modified. These bits along with bits in the LMLOCK field (FLASH_LMLR), determine if the block is locked from program or erase. An “OR” of FLASH_LMLR and FLASH_SLMLR determine the final lock status. Refer to [Section 13.3.2.2, “Low/Mid Address Space Block Locking Register \(FLASH_LMLR\)”](#) for more information on FLASH_LMLR.

Address: Base (0xC3F8_8000) + 0x000C

Access: R/W

¹ The reset value of these bits is determined by flash values in the shadow row. An erased array sets the reset value to 1.

Figure 13-8. Secondary Low/Mid Address Space Block Locking Register (FLASH_SLMLR)

Table 13-9. FLASH_SLMLR Field Descriptions

Field	Description
0 SLE	Secondary low and mid address lock enable. Enables the secondary lock fields (SSLOCK, SMLOCK, and SLLOCK) to be set or cleared by register writes. This bit is a status bit only, and cannot be written to or cleared, and the reset value is 0. The method to set this bit is to provide a password, and if the password matches, the SLE bit is set to reflect the status of enabled, and is enabled until a reset operation occurs. For SLE, the password 0xC3C3_3333 must be written to the FLASH_SLMLR. 0 Secondary low and mid address locks are disabled, and cannot be modified. 1 Secondary low and mid address locks are enabled to be written.
1–10	Reserved.
11 SSLOCK	Secondary shadow lock. An alternative method to use to lock the shadow row from programs and erases. SSLOCK has the same description as SLOCK in Section 13.3.2.2, “Low/Mid Address Space Block Locking Register (FLASH_LMLR).” SSLOCK is not writable unless SLE is high.
12–13	Reserved.
14–15 SMLOCK[1:0]	Secondary mid address block lock. Alternative method to use to lock the mid address space blocks from programs and erases. SMLOCK has the same description as MLOCK in Section 13.3.2.2, “Low/Mid Address Space Block Locking Register (FLASH_LMLR).” SMLOCK is not writable unless SLE is set. In the event that blocks are not present (due to configuration or total memory size), the SMLOCK bits default to locked, and not writable.
16–25	Reserved.
26–31 SLLOCK[5:0]	Secondary low address block lock. These bits are an alternative method that to use to lock the low address space blocks from programs and erases. SLLOCK has the same description as LLOCK in Section 13.3.2.2, “Low/Mid Address Space Block Locking Register (FLASH_LMLR).” SLLOCK is not writable unless SLE is high. In the event that blocks are not present (due to configuration or total memory size), the SLLOCK bits default to locked, and are not writable.

13.3.2.5 Low/Mid Address Space Block Select Register (FLASH_LMSR)

The FLASH_LMSR provides a means to select blocks to be operated on during erase.

Address: Base (0xC3F8_8000) + 0x0010

Access: R/W

Figure 13-9. Low/Mid Address Space Block Select Register (FLASH_LMSR)

Table 13-10. FLASH_LMSR Field Descriptions

Field	Description
0–13	Reserved.
14–15 MSEL[1:0]	<p>Mid address space block select. Values in the selected register signify that a block(s) is or is not selected for erase. The reset value for the select registers is 0. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable after an interlock write is completed or if a high voltage operation is suspended. In the event that blocks are not present (due to configuration or total memory size), the corresponding SELECT bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. A description of how blocks are numbered is detailed in Section 13.3.2.2, “Low/Mid Address Space Block Locking Register (FLASH_LMLR).”</p> <p>0b0000 Mid address space blocks are <i>not</i> selected for erase 0b0001 One mid address space block is selected for erase 0b0011 Two mid address space blocks are selected for erase</p>
16–25	Reserved.
26–31 LSEL[5:0]	<p>Low address space block select. Used to select blocks in the low address space; these have the same description and attributes as the MSEL bits</p> <p>0b0000 Low address space blocks are <i>not</i> selected for erase 0b0001 One low address space block is selected for erase 0b0011 Two low address space blocks are selected for erase 0b0111 Three low address space blocks are selected for erase 0b1111 Four low address space blocks are selected for erase 0b0001_1111 Five low address space blocks are selected for erase 0b0011_1111 Six low address space blocks are selected for erase</p>

13.3.2.6 High Address Space Block Select Register (FLASH_HSR)

The FLASH_HSR allows the application to select the high address flash blocks on which to operate.

Address: Base (0xC3F8_8000) + 0x0014

Access: R/W

Figure 13-10. High Address Space Block Select Register (FLASH_HSR)

Table 13-11. FLASH_HSR Field Descriptions

Field	Description
0–19	Reserved.
20–31 HBSEL[11:0]	High address space block select. Has the same characteristics as MSEL. For more information refer to Section 13.3.2.5, “Low/Mid Address Space Block Select Register (FLASH_LMSR).” 0b0000 High address space blocks are <i>not</i> selected for erase 0b0001 One high address space block is selected for erase 0b0011 Two high address space blocks are selected for erase 0b0111 Three high address space blocks are selected for erase 0b1111 Four high address space blocks are selected for erase 0b0001_1111 Five high address space blocks are selected for erase 0b0011_1111 Six high address space blocks are selected for erase 0b0111_1111 Seven high address space blocks are selected for erase 0b1111_1111 Eight high address space blocks are selected for erase 0b0001_1111_1111 Nine high address space blocks are selected for erase 0b0011_1111_1111 Ten high address space blocks are selected for erase 0b0111_1111_1111 Eleven high address space blocks are selected for erase 0b1111_1111_1111 Twelve high address space blocks are selected for erase

13.3.2.7 Address Register (FLASH_AR)

The FLASH_AR provides the first failing address in the event of ECC event error (FLASH_MCR[EER] set), as well as providing the address of a failure that occurs in a state machine operation (FLASH_MCR[PEG] cleared). ECC event errors take priority over state machine errors. This is especially valuable in the event of a RWW operation, where the read senses an ECC error and the state machine fails simultaneously. This address is always a doubleword address that selects 64 bits.

In normal operating mode, the FLASH_AR is not writable.

Address: Base (0xC3F8_8000) + 0x0018

Access: R/W

Figure 13-11. Address Register (FLASH_AR)

Table 13-12. FLASH_AR Field Descriptions

Field	Description
0–9	Reserved.
10–28 ADDR[3:21]	Doubleword address of first failing address in the event of an ECC error, or the address of a failure occurring during state machine operation.
29–31 ADDR[0:2]	Always read as 0.

13.3.2.8 Flash Bus Interface Unit Control Register (FLASH_BIUCR)

The FLASH_BIUCR is the control register for the set up and control of the flash interface. This register must not be written while executing from flash. Only use a 32-bit write operation to write to this register.

Address: Base (0xC3F8_8000) + 0x001C

Access: R/W

Table 13-13. FLASH_BIUCR Field Descriptions (continued)

Bits	Description
16–18 APC ¹	Address pipelining control. Used to control the number of cycles between pipelined access requests. This field must be set to a value corresponding to the operating frequency of the system clock. The required settings are documented in Table 13-14 . 000 Reserved 001 Access requests require one hold cycle 010 Access requests require two hold cycles ... 110 Access requests require 6 hold cycles 111 No address pipelining
19–20 WWSC ¹	Write wait state control. Used to control the timing for array writes. This field must be set to a value corresponding to the operating frequency of the system clock. The required settings are documented in Table 13-14 . 00 Reserved 01 One wait state 10 Two wait states 11 Three wait states
21–23 RWSC ¹	Read wait state control. Used to control the flash array access time for array reads. This field must be set to a value corresponding to the operating frequency of the system clock. The required settings are documented in Table 13-14 . 000 Zero wait states 001 One wait state ... 111 Seven wait states
24–25 DPFEN	Data prefetch enable. Enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 00 No prefetching is triggered by a data read access 01 Prefetching can be triggered only by a data burst read access 10 Reserved 11 Prefetching can be triggered by any data read access
26–27 IPFEN	Instruction prefetch enable. Enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 00 No prefetching is triggered by an instruction read access 01 Prefetching can be triggered only by an instruction burst read access 10 Reserved 11 Prefetching can be triggered by any instruction read access

Table 13-13. FLASH_BIUCR Field Descriptions (continued)

Bits	Description
28–30 PFLIM	<p>Prefetch limit. Controls the prefetch algorithm used by the FBIU prefetch controller. This field defines a limit on the maximum number of sequential prefetches which are attempted between buffer misses. This field is cleared by hardware reset.</p> <p>000 No prefetching is performed</p> <p>001 A single additional line (next sequential) is prefetched on a buffer miss</p> <p>010 Up to two additional lines can be prefetched following each buffer miss before prefetching is halted. A single additional line (next sequential) is prefetched on a buffer miss, and the next sequential line is prefetched on a buffer hit (if not already present).</p> <p>011 Up to three additional lines can be prefetched following each buffer miss before prefetching is halted. Only a single additional prefetch is initiated after each buffer hit or miss.</p> <p>100 Up to four additional lines can be prefetched following each buffer miss before prefetching is halted. Only a single additional prefetch is initiated after each buffer hit or miss.</p> <p>101 Up to five additional lines can be prefetched following each buffer miss before prefetching is halted. Only a single additional prefetch is initiated after each buffer hit or miss.</p> <p>110 An unlimited number of additional lines can be prefetched following each buffer miss. Only a single additional prefetch is initiated on each buffer hit or miss.</p> <p>111 Reserved</p>
31 BFEN	<p>FBIU line read buffers enable. Enables or disables line read buffer hits. It is also used to invalidate the buffers. These bits are cleared by hardware reset.</p> <p>0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared.</p> <p>1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits can be set when the buffers are successfully filled.</p> <p>Note: Disable prefetching before invalidating the buffers. This includes starting a program or erase operation, or turning on and off the buffers.</p>

¹ APC, WWSC, and RWSC values are determined by the maximum frequency of operation. Refer to [Table 13-14](#).

Table 13-14. FLASH_BIU Settings vs. Frequency of Operation

Maximum Frequency (MHz)	APC	RWSC	WWSC	DPFEN	IPFEN	PFLIM	BFEN
up to and including 82 MHz ¹	0b001	0b001	0b01	0b00, 0b01, or 0b11 ²	0b00, 0b01, or 0b11 ²	0b000- 0b110 ³	0b0, 0b1 ⁴
up to and including 102 MHz ⁵	0b001	0b010	0b01	0b00, 0b01, or 0b11 ²	0b00, 0b01, or 0b11 ²	0b000- 0b110 ³	0b0, 0b1 ⁴
up to and including 132 MHz ⁶	0b010	0b011	0b01	0b00, 0b01, or 0b11 ²	0b00, 0b01, or 0b11 ²	0b000- 0b110 ³	0b0, 0b1 ⁴
Default Setting after Reset	0b111	0b111	0b11	0b00	0b00	0b000	0b0

¹ This setting allows for 80 MHz system clock with 2% frequency modulation.

² For maximum flash performance, set to 0b11.

³ For maximum flash performance, set to 0b110.

⁴ For maximum flash performance, set to 0b1.

⁵ This setting allows for 100 MHz system clock with 2% frequency modulation.

⁶ This setting allows for 130 MHz system clock with 2% frequency modulation.

13.3.2.9 Flash Bus Interface Unit Access Protection Register (FLASH_BIUAPR)

The FLASH_BIUAPR controls access protection for the flash from masters on the crossbar switch. Use a 32-bit write operation only to this register.

Address: Base (0xC3F8_8000) + 0x0020

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 13-15. FLASH_BIUAPR Field Descriptions

Field	Description
0–23	Reserved. Reads/Writes have no effect.
24–31 MnAP [0:1]	Master <i>n</i> access protection. Controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. Refer to Table 7-3 . 00 No accesses can be performed by this master 01 Only read accesses can be performed by this master 10 Only write accesses can be performed by this master 11 Both read and write accesses can be performed by this master These fields are identified as follows: M0AP= MCU core M1AP= Nexus M2AP= eDMA M3AP= EBI

13.4 Functional Description

13.4.1 Flash Bus Interface Unit (FBIU)

The Flash BIU interfaces between the system bus and the flash memory interface unit and generates read and write enables, the flash array address, write size, and write data as inputs to the flash memory interface unit (MI). The Flash BIU captures read data from the MI and drives it on the system bus. Up to two lines (1 line is a 256-bit width) of data or instructions are buffered by the Flash BIU. Lines can be prefetched in advance of being requested by the system bus interface, allowing single-cycle read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering can be restricted to instruction accesses only, data accesses only, or can be unrestricted. Prefetch triggering can also be controlled on a per-master basis.

Access protections can be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

13.4.1.1 FBIU Basic Interface Protocol

The Flash BIU interfaces to the flash array by driving addresses and read or write enable signals to the flash memory interface unit. The access time of the flash is determined by the settings of the wait state control bits in the FLASH_BIUCR, as well as the pipelining of addresses.

The Flash BIU also has the capability of extending the normal system bus access timing by inserting additional primary (initial access) wait states for reads and burst reads. This capability is provided to allow emulation of other memories which have different access time characteristics.

13.4.1.2 FBIU Access Protections

The Flash BIU provides hardware configurable access protections for both read and write cycles from masters. It allows restriction of read and write requests on a per-master basis. The FBIU also supports software configurable access protections. Detection of a protection violation results in an error response from the Flash BIU to the system bus.

13.4.1.3 Flash Read Cycles—Buffer Miss

Read data is normally stored in the least-recently updated line read buffer in parallel with the requested data being forwarded to the system bus.

13.4.1.4 Flash Read Cycles—Buffer Hit

Single clock read responses to the system bus are possible with the Flash BIU when the requested read access is buffered.

13.4.1.5 Flash Access Pipelining

Accesses to the flash array can be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the Flash BIU. Request pipelining allows for improved performance by reducing the access latency seen by the system bus master. Access pipelining can be applied to both read and write cycles by the flash array.

13.4.1.6 Flash Error Response Operation

The flash array can terminate a requested access with an error. This can occur due to an uncorrectable ECC error, an access control violation, or because of improper access sequencing during program/erase operations. When an error response is received, the Flash BIU marks a line read buffer as invalid. An error response can be signaled on read or write operations.

13.4.1.7 FBIU Line Read Buffers and Prefetch Operation

The Flash BIU contains a pair of 256-bit line read buffers which are used to hold data read from the flash array. Each buffer operates independently and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis. Bus masters can be enabled or disabled from triggering prefetches, and triggering can be further restricted based on whether a read access is for instruction or data and whether or not it is a burst access. A read access to the Flash BIU can trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented to the next-higher 32-byte boundary, and a flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is loaded into the buffer which is not being used to satisfy the original request.

Buffers can be in one of six states, listed here in prioritized order:

- Invalid—the buffer contains no valid data.
- Used—the buffer contains valid data which has been provided to satisfy a burst type read.
- Valid—the buffer contains valid data which has been provided to satisfy a single type read.
- Prefetched—the buffer contains valid data which has been prefetched to satisfy a potential future access.
- Busy—the buffer is currently being used to satisfy a burst read.
- Busy fill—the buffer has been allocated to receive data from the flash array, and the array access is still in progress.

Selection of a buffer to fill on a buffer miss is based on this prioritized order beginning with the first item (invalid). Selection of a buffer to fill on a triggered prefetch is based on the buffer which is not being used to satisfy the triggering access.

The consequences of this replacement policy are that buffers are selected for filling on a ‘least recently updated’ basis when prefetching, and on a ‘most recently emptied’ basis for demand fetches (that is, a fetch which is actually satisfying a current system bus access). This policy allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in [Section 13.3.2.8, “Flash Bus Interface Unit Control Register \(FLASH_BIUCR\).”](#) More aggressive prefetching increases power due to the number of wasted (discarded) prefetches, but can increase performance by lowering average read latency.

13.4.1.8 FBIU Instruction/Data Prefetch Triggering

Prefetch triggering can be enabled for instruction reads. Triggering can be enabled for all instruction reads or only for instruction burst reads. Prefetch triggering can be enabled for data reads. Triggering can be enabled for all data reads or only for data burst reads. Prefetches are not triggered by write cycles.

13.4.1.9 FBIU Per-Master Prefetch Triggering

Prefetch triggering can be controlled for individual bus masters. System bus accesses indicate the requesting master.

13.4.1.10 FBIU Buffer Invalidation

The line read buffers can be invalidated under hardware and software control. Buffers are automatically invalidated whenever the buffers are turned on or off, or at the beginning of a program or erase operation.

NOTE

Disable prefetching before invalidating the buffers. This includes starting a program or erase operation, or turning on and off the buffers.

13.4.1.11 Flash Wait-state Emulation

Emulation of other memory array timings are supported by the Flash BIU. This functionality can be useful to maintain the access timing for blocks of memory which were used to overlay flash blocks for the purpose of system calibration or tuning during code development.

The Flash BIU inserts additional primary wait states according to user-programmable values for primary wait states. When these inputs are non-zero, additional cycles are added to system bus transfers. Normal system bus termination is extended. In addition, no line read buffer prefetches are initiated, and buffer hits are ignored.

13.4.2 Flash Memory Array: User Mode

In user (normal) operating mode the flash module can be read, written (register writes and interlock writes), programmed, or erased. The following subsections define all actions that can be performed in normal operating mode. The registers mentioned in these sections are detailed in [Section 13.3.2, “Register Descriptions.”](#)

13.4.2.1 Flash Read and Write

The default state of the flash module is read. The main and shadow address space can be read only in the read state. The module configuration register (FLASH_MCR) is always available for read. The flash module enters the read state on reset. The flash module is in the read state under four sets of conditions:

- The read state is active when FLASH_MCR[STOP] = 0 (user mode read).
- The read state is active when FLASH_MCR[PGM] = 1 and/or FLASH_MCR[ERS] = 1 and high voltage operation is ongoing (read while write).

NOTE

Reads done to the partitions being operated on (either erased or programmed) result in an errors and the FLASH_MCR[RWE] bit is set.

- The read state is active when FLASH_MCR[PGM] = 1 and FLASH_MCR[PSUS] = 1 in the MCR. (Program suspend).
- The read state is active when FLASH_MCR[ERS] = 1 and FLASH_MCR[ESUS] = 1 and FLASH_MCR[PGM] = 0 in the MCR. (Erase suspend).

NOTE

Flash core reads are done through the BIU. In many cases the BIU does page buffering to allow sequential reads to be done with higher performance. This can create a data coherency issue that must be handled with software. Data coherency can be an issue after a program or erase operation, as well as shadow row operations.

In flash normal operating mode, registers can be written and the flash array can be written to do interlock writes.

Reads attempted to invalid locations result in indeterminate data. Invalid locations occur when addressing is done to blocks that do not exist in non 2^n array sizes.

Interlock writes attempted to invalid locations (due to blocks that do not exist in non 2^n array sizes), result in an interlock occurring, but attempts to program or erase these blocks do not occur since they are forced to be locked.

Refer to [Section 13.3.2.2, “Low/Mid Address Space Block Locking Register \(FLASH_LMLR\), Section 13.3.2.3, “High Address Space Block Locking Register \(FLASH_HLR\)”](#) and [Section 13.3.2.4, “Secondary Low/Mid Address Space Block Locking Register \(FLASH_SLMLR\)”](#) for more information.

13.4.2.2 Read While Write (RWW)

The flash core is divided into partitions. Partitions are always comprised of two or more blocks. Partitions are used to determine read while write (RWW) groupings. While a write (program or erase) is being done within a given partition, a read can be simultaneously executed to any other partition. Partitions are listed in [Table 13-3](#). Each partition in high address space comprises of two 128-KB blocks. Note that the shadow block has unique RWW restrictions described in [Section 13.4.2.5, “Flash Shadow Block.”](#)

The flash core is also divided into blocks to implement independent erase or program protection. The shadow block exists outside the normal address space and is programmed, erased and read independently of the other blocks. The shadow block is included to support systems that require NVM for security or system initialization information.

A software mechanism is provided to independently lock or unlock each block in high-, mid-, and low-address space against program and erase.

13.4.2.3 Flash Programming

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1. Addresses in locked/disabled blocks cannot be programmed. The user can program the values in any or all of eight words within a page in a single program sequence. Word addresses are selected using bits 4:2 of the page-bound word.

Whenever a program operation occurs, ECC bits are programmed. ECC is handled on a 64-bit boundary. Thus, if only 1 word in any given 64-bit ECC segment is programmed, do not program the adjoining word (in that segment) because the ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word results in an operation failure. All programming operations must be from 64 bits to 256 bits, and be 64-bit aligned. The programming operation must completely fill the selected ECC segments within the page.

The program operation consists of the following sequence of events:

1. Change the value in the FLASH_MCR[PGM] bit from a 0 to a 1.

NOTE

Ensure the block that contains the address to be programmed is unlocked. Refer to [Section 13.3.2.2, “Low/Mid Address Space Block Locking Register \(FLASH_LMLR\)”](#), [Section 13.3.2.3, “High Address Space Block Locking Register \(FLASH_HLR\)”](#) and [Section 13.3.2.4, “Secondary Low/Mid Address Space Block Locking Register \(FLASH_SLMLR\)”](#) for more information.

2. Write the first address to be programmed in the flash module with the program data. This write is referred to as a program data interlock write. An interlock write can either be an aligned-word or doubleword.
3. If more than 1 word or doubleword is to be programmed, write each additional address in the page with data to be programmed. This is referred to as a program data write. All unwritten data words default to 0xFFFF FFFF.
4. Write a logic 1 to the FLASH_MCR[EHV] bit to start the internal program sequence or skip to step 9 to terminate.
5. Wait until the FLASH_MCR[DONE] bit goes high.
6. Confirm FLASH_MCR[PEG] = 1.
7. Write a logic 0 to the FLASH_MCR[EHV] bit.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic 0 to the FLASH_MCR[PGM] bit to terminate the program sequence.

The program sequence is presented graphically in [Figure 13-14](#). The program suspend operation detailed in [Figure 13-14](#) is discussed in [Section 13.4.2.3.2, “Flash Program Suspend/Resume.”](#)

The first write after a program is initiated determines the page address to be programmed. The program can be initiated with the 0 to 1 transition of the FLASH_MCR[PGM] bit or by clearing the FLASH_MCR[EHV] bit at the end of a previous program. This first write is referred to as an interlock write. If the program is not an erase-suspended program, the interlock write determines if the shadow or normal array space is programmed and causes FLASH_MCR[PEAS] to be set/cleared.

In the case of an erase-suspended program, the value in FLASH_MCR[PEAS], is retained from the erase.

An interlock write must be performed before setting FLASH_MCR[EHV]. The user can terminate a program sequence by clearing FLASH_MCR[PGM] prior to setting FLASH_MCR[EHV].

If multiple writes are done to the same location the data for the last write is used in programming.

While FLASH_MCR[DONE] is low, FLASH_MCR[EHV] is high and FLASH_MCR[PSUS] is low the user can clear FLASH_MCR[EHV], resulting in a program abort. A program abort forces the module to step 8 of the program sequence. An aborted program results in FLASH_MCR[PEG] being set low, indicating a failed operation. The data space being operated on before the abort contains indeterminate data. The user cannot abort a program sequence while in program suspend.

WARNING

Aborting a program operation leaves the flash core addresses being programmed in an indeterminate data state. This can be recovered by executing an erase on the affected blocks.

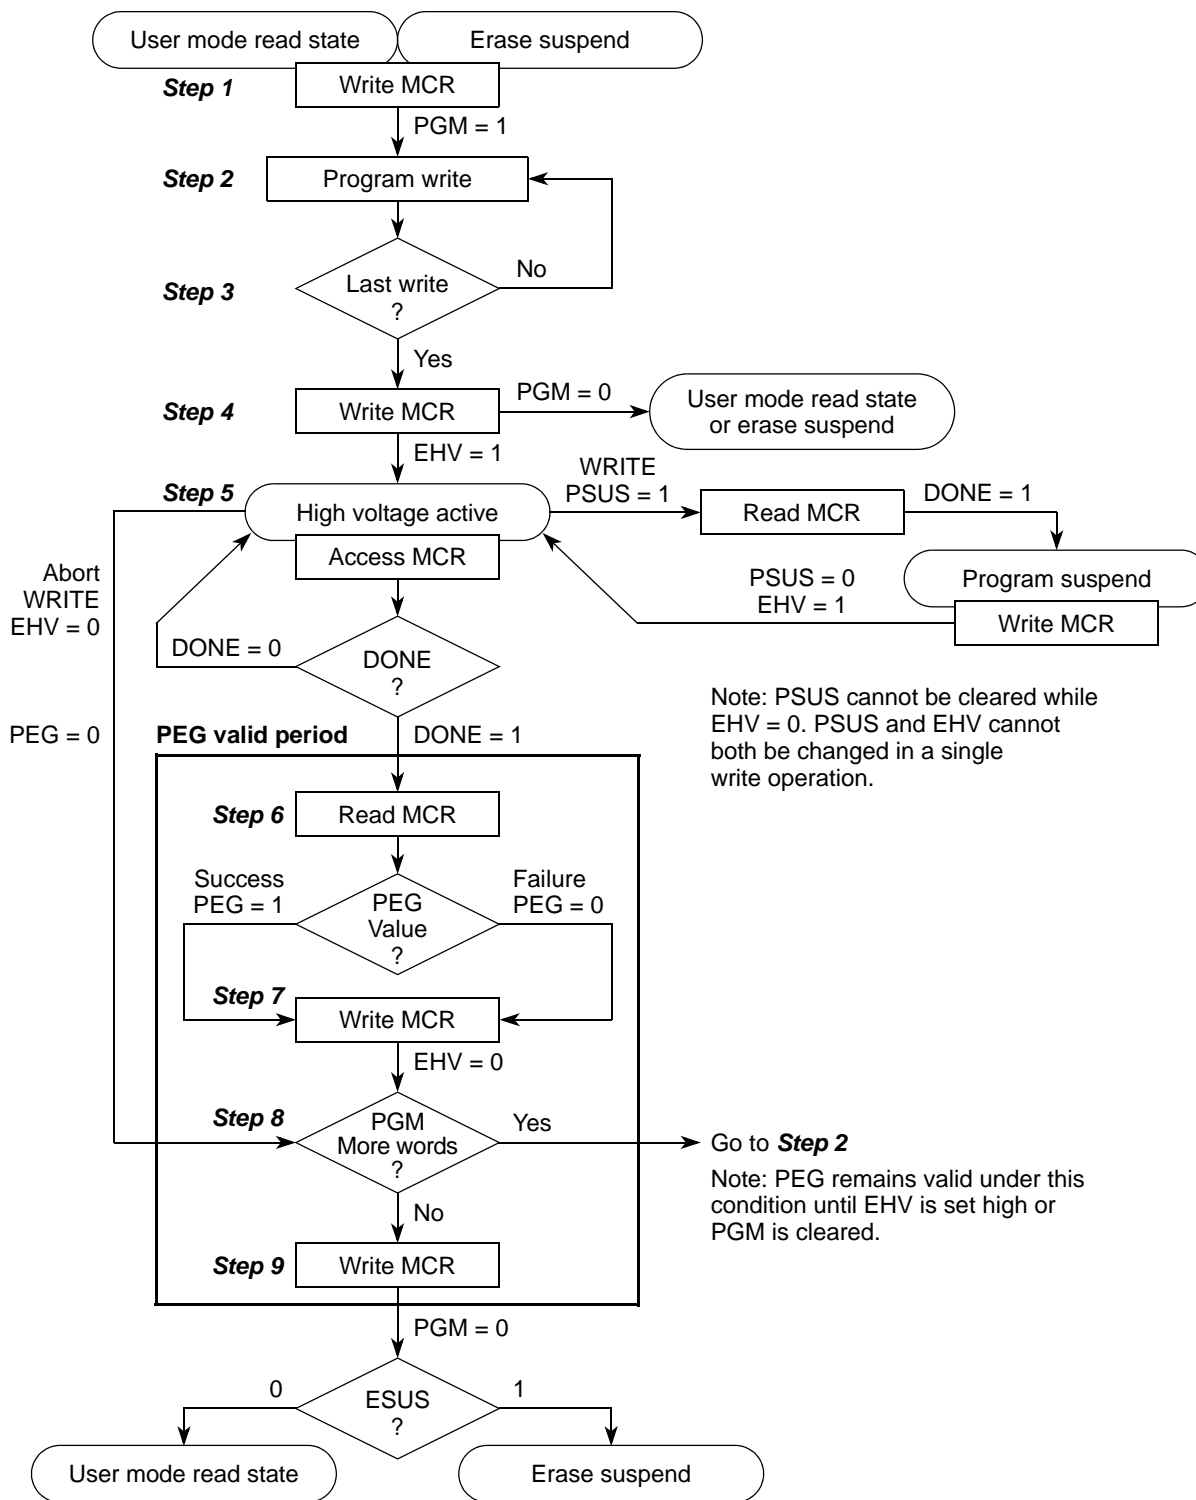

Figure 13-14. Program Sequence

13.4.2.3.1 Software Locking

A software mechanism is provided to independently lock/unlock each high, mid, and low address space against program and erase.

Software Locking is done through the FLASH_LMLR (low/mid address space block locking register), FLASH_SLMLR (secondary low/mid address space block locking register), or FLASH_HLR (high address space block locking register). These can be written through register writes, and can be read through register reads.

When the program/erase operations are enabled through hardware, software locks are enforced through doing register writes.

13.4.2.3.2 Flash Program Suspend/Resume

The program sequence can be suspended to allow read access to the flash core. It is not possible to erase or program during a program suspend. Do not attempt interlock writes during program suspend.

A program suspend can be initiated by changing the value of the FLASH_MCR[PSUS] bit from a 0 to a 1. FLASH_MCR[PSUS] can be set high at any time when FLASH_MCR[PGM] and FLASH_MCR[EHV] are high. A 0 to 1 transition of FLASH_MCR[PSUS] causes the flash module to start the sequence to enter program suspend, which is a read state. The module is not suspended until FLASH_MCR[DONE] = 1. At this time, flash core reads can be attempted. After it is suspended, the flash core can only be read. Reads to the blocks being programmed/erased return indeterminate data.

The program sequence is resumed by writing a logic 0 to FLASH_MCR[PSUS]. FLASH_MCR[EHV] must be set to a 1 before clearing FLASH_MCR[PSUS] to resume operation. When the operation resumes, the flash module continues the program sequence from one of a set of predefined points. This can extend the time required for the program operation.

13.4.2.4 Flash Erase

Erase changes the value stored in all bits of the selected blocks to logic 1. Locked or disabled blocks cannot be erased. If multiple blocks are selected for erase during an erase sequence, the blocks are erased sequentially starting with the lowest numbered block and terminating with the highest. Aborting an erase operation leaves the flash core blocks being erased in an indeterminate data state. This can be recovered by executing an erase on the affected blocks.

The erase sequence consists of the following sequence of events:

1. Change the value in the FLASH_MCR[ERS] bit from 0 to a 1.
2. Select the block, or blocks to be erased by writing ones to the appropriate registers in FLASH_LMSR or FLASH_HSR. If the shadow row is to be erased, this step can be skipped, and FLASH_LMSR and FLASH_HSR are ignored. For shadow row erase, refer to section [Section 13.4.2.5, “Flash Shadow Block”](#) for more information.

NOTE

Lock and Select are independent. If a block is selected and locked, no erase occurs. Refer to [Section 13.3.2.2, “Low/Mid Address Space Block Locking Register \(FLASH_LMLR\), Section 13.3.2.3, “High Address Space Block Locking Register \(FLASH_HLR\)”](#) and [Section 13.3.2.4, “Secondary Low/Mid Address Space Block Locking Register \(FLASH_SLMLR\)”](#) for more information.

3. Write to any address in flash. This is referred to as an erase interlock write.
4. Write a logic 1 to the FLASH_MCR[EHV] bit to start an internal erase sequence or skip to step 9 to terminate.
5. Wait until the FLASH_MCR[DONE] bit goes high.
6. Confirm FLASH_MCR[PEG] = 1.
7. Write a logic 0 to the FLASH_MCR[EHV] bit.
8. If more blocks are to be erased, return to step 2.
9. Write a logic 0 to the FLASH_MCR[ERS] bit to terminate the erase.

The erase sequence is presented graphically in [Figure 13-15](#). The erase suspend operation detailed in [Figure 13-15](#) is discussed in [Section 13.4.2.4.1, “Flash Erase Suspend/Resume.”](#)

After setting FLASH_MCR[ERS], one write, referred to as an interlock write, must be performed before FLASH_MCR[EHV] can be set to a 1. Data words written during erase sequence interlock writes are ignored. The user can terminate the erase sequence by clearing FLASH_MCR[ERS] before setting FLASH_MCR[EHV].

An erase operation can be aborted by clearing FLASH_MCR[EHV] assuming FLASH_MCR[DONE] is low, FLASH_MCR[EHV] is high and FLASH_MCR[ESUS] is low. An erase abort forces the module to step 8 of the erase sequence. An aborted erase results in FLASH_MCR[PEG] being set low, indicating a failed operation. The blocks being operated on before the abort contain indeterminate data. The user cannot abort an erase sequence while in erase suspend.

WARNING

Aborting an erase operation leaves the flash core blocks being erased in an indeterminate data state. This can be recovered by executing an erase on the affected blocks.

13.4.2.4.1 Flash Erase Suspend/Resume

The erase sequence can be suspended to allow read access to the flash core. The erase sequence can also be suspended to program (erase-suspended program) the flash core. A program started during erase suspend can in turn be suspended. Only one erase suspend and one program suspend are allowed at a time during an operation. It is not possible to erase during an erase suspend, or program during a program suspend. During suspend, all reads to flash core locations targeted for program and blocks targeted for erase return indeterminate data. Programming locations in blocks targeted for erase during erase-suspended program can result in corrupted data.

An erase suspend operation is initiated by setting the FLASH_MCR[ESUS] bit. FLASH_MCR[ESUS] can be set to a 1 at any time when FLASH_MCR[ERS] and FLASH_MCR[EHV] are high and FLASH_MCR[PGM] is low. A 0 to 1 transition of FLASH_MCR[ESUS] causes the flash module to start the sequence which places it in erase suspend. The user must wait until FLASH_MCR[DONE] = 1 before the module is suspended and further actions are attempted. After it is suspended, the array can be read or a program sequence can be initiated (erase-suspended program). Before initiating a program sequence the user must first clear FLASH_MCR[EHV]. If a program sequence is initiated the value of the FLASH_MCR[PEAS] is not reset. These values are fixed at the time of the first interlock of the erase. Flash core reads while FLASH_MCR[ESUS] = 1 from the blocks being erased return indeterminate data. The erase operation is resumed by clearing the FLASH_MCR[ESUS] bit. The flash continues the erase sequence from one of a set of predefined points. This can extend the time required for the erase operation.

WARNING

In an erase-suspended program, programming flash locations in blocks which were being operated on in the erase can corrupt flash core data.

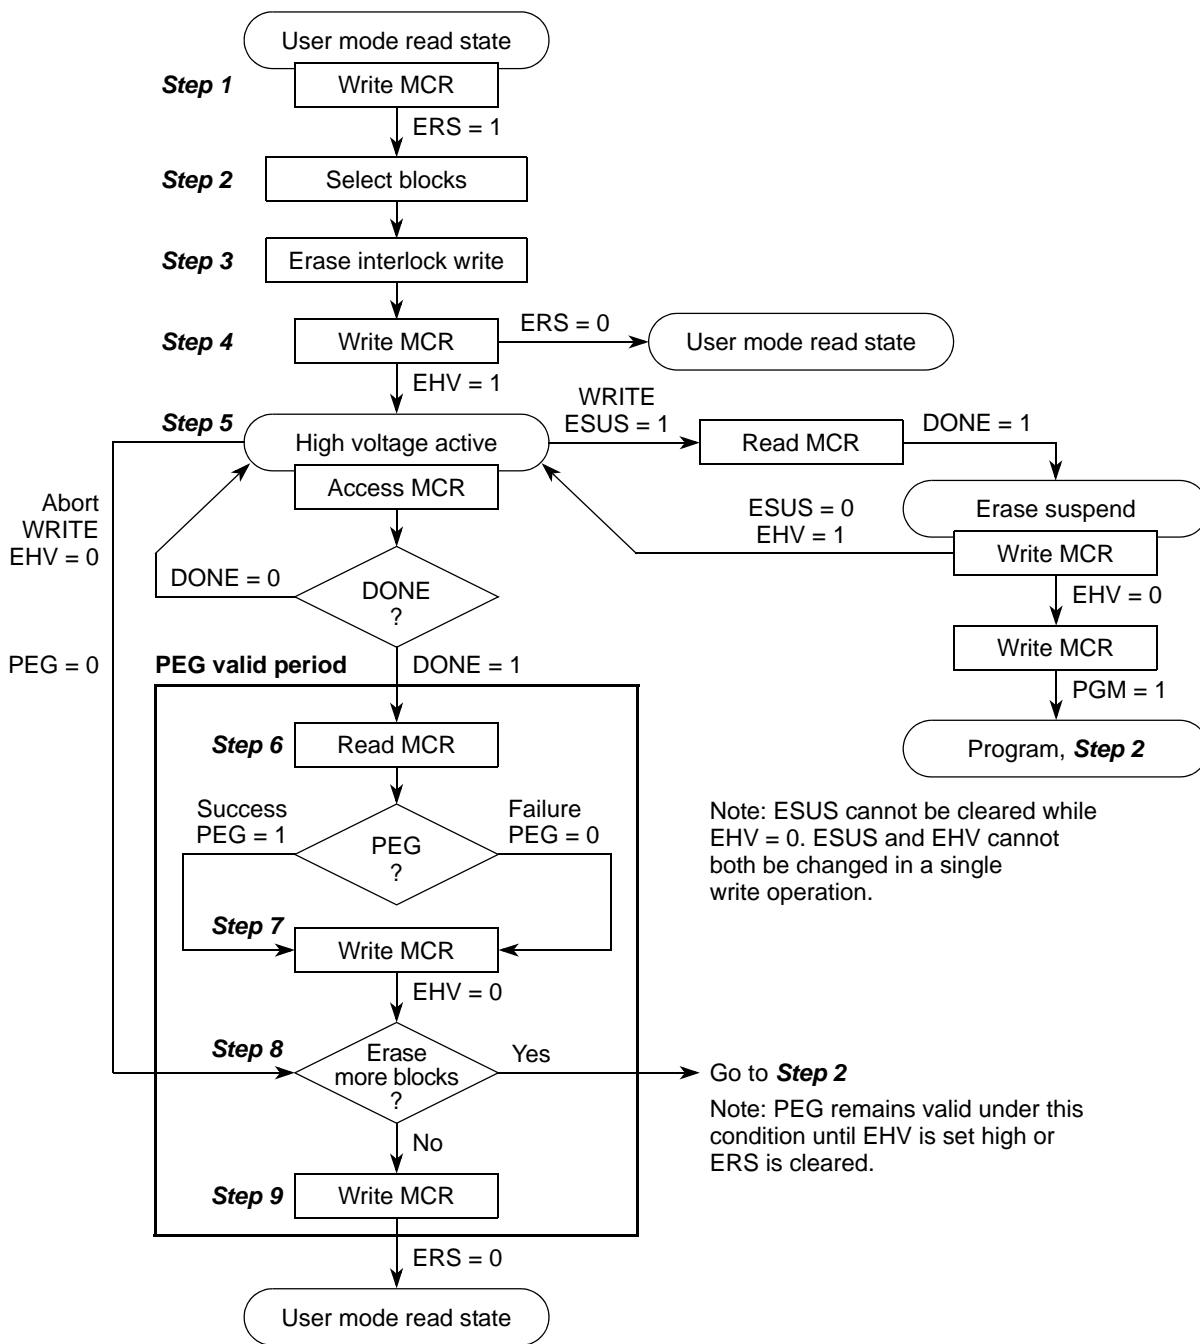

Figure 13-15. Erase Sequence

13.4.2.5 Flash Shadow Block

The flash shadow block is a memory-mapped block in the flash memory map. Program and erase of the shadow block are enabled only when `FLASH_MCR[PEAS] = 1`. After the user has begun an erase operation on the shadow block, the operation cannot be suspended to program the main address space and vice-versa. The user must terminate the shadow erase operation to program or erase the main address space.

NOTE

If an erase of user space is requested, and a suspend is done with attempts to erase suspend program shadow space, this attempted program is directed to user space as dictated by the state of `FLASH_MCR[PEAS]`. Likewise an attempted erase suspended program of user space, while the shadow space is being erased, is directed to shadow space as dictated by the state of `FLASH_MCR[PEAS]`.

The shadow block cannot utilize the RWW feature. After an operation is started in the shadow block, a read cannot be done to the shadow block, or any other block. Likewise, after an operation is started in a block in low/mid/high address space, a read cannot be done in the shadow block.

The shadow block contains information on how the lock registers are reset. The first and second words can be used for reset configuration words. All other words can be used for user defined functions or other configuration words.

The shadow block can be locked/unlocked against program or erase by using the `FLASH_LMLR` or `FLASH_SLMLR` discussed in [Section 13.3.2, “Register Descriptions.”](#)

Programming of the shadow row has similar restrictions to programming the array in terms of how ECC is calculated. Refer to [Section 13.4.2.3, “Flash Programming”](#) for more information. Only one program is allowed per 64 bit ECC segment between erases. Erase of the shadow row is done similarly as an array erase. Refer to [Section 13.4.2.4, “Flash Erase”](#) for more information.

13.4.2.6 Censorship

Censorship logic disables access to internal flash based on the censorship control word value and the `BOOTCFG[0:1]` bits in the `SIU_RSR`. This prevents modification of the `FLASH_BIUAPR` bitfields associated with all masters except the core based on the censorship control word value, the `BOOTCFG[0:1]` bits in the `SIU_RSR`, and the `EXTM` bit in the `EBI_MCR`. Also, censorship logic sets the boot default value to external-with-external-master access disabled based on the value of the censorship control word and a TCU input signal.

13.4.2.6.1 Censorship Control Word

The censorship control word is a 32-bit value located at the base address of the shadow row plus `0x1E0`. The flash module latches the value of the control word prior to the negation of system reset. Censorship logic uses the value latched in the flash module to disable access to internal flash, disable the NDI, prevent modification of the `FLASH_BIUAPR` bitfields, and/or set the boot default value.

13.4.2.6.2 Flash Disable

Censorship logic disables read and write access to internal flash according to the logic presented in [Table 13-16](#).

[Table 13-16](#) shows the encoding of the BOOTCFG signals in conjunction with the value stored in the Censorship word in the shadow row of internal flash memory. The table also shows: the name of the boot mode; whether the internal flash memory is enabled or disabled; whether the Nexus port is enabled or disabled; whether the password downloaded in serial boot mode is compared with a fixed ‘public’ password or compared to a user programmable flash password.

Table 13-16. Flash Access Disable Logic

BOOTCFG ¹ [0:1]	Censorship Control 0x00FF_FDE0 (Upper Half)	Serial Boot Control 0x00FF_FDE2 (Lower Half)	Boot Mode Name	Internal Flash State	Nexus State ²	Serial Password
00	!0x55AA	Don't care	Internal–Censored	Enabled	Disabled	Flash
	0x55AA		Internal –Public	Enabled	Enabled	Public
01	Don't care	0x55AA	Serial –Flash password	Enabled	Disabled	Flash
		!0x55AA	Serial–Public password	Disabled	Enabled	Public
10	!0x55AA	Don't care	External –No Arbitration–Censored	Disabled	Enabled	Public
	0x55AA		External –No Arbitration–Public	Enabled	Enabled	Public
11	!0x55AA	Don't care	External –External Arbitration–Censored	Disabled	Enabled	Public
	0x55AA		External –External Arbitration–Public	Enabled	Enabled	Public

‘!’ =‘NOT’ means any value other than the value specified

¹ BOOTCFG[0:1] bits are located in the SIU_RSR.

² The Nexus port controller is held in reset when in censored mode.

The FBIU returns a bus error if an access is attempted while flash access is disabled. Flash access is any read, write or execute access.

13.4.2.6.3 FLASH_BIUAPR Modification

Censorship logic prevents modification of the access protection register (FLASH_BIUAPR) bit fields associated with all masters except the core according to the logic presented in [Table 13-17](#).

Table 13-17. PFBAPR Modification Logic

BOOTCFG ¹		Censorship Control Word		EXTM ²	PFBAPR Bitfields Writable
[0]	[1]	Upper Half	Lower Half		
0	0	0x55AA	0xXXXX	0	Yes
0	0	!0x55AA	0xXXXX	0	Yes
1	0	0x55AA	0xXXXX	0	Yes
1	0	!0x55AA	0xXXXX	0	Yes
1	1	0x55AA	0xXXXX	0	Yes
1	1	!0x55AA	0xXXXX	0	Yes
0	1	0xXXXX	0x55AA	0	Yes
0	1	0xXXXX	!0x55AA	0	Yes
0	0	0x55AA	0xXXXX	1	Yes
0	0	!0x55AA	0xXXXX	1	No
1	0	0x55AA	0xXXXX	1	Yes
1	0	!0x55AA	0xXXXX	1	No
1	1	0x55AA	0xXXXX	1	Yes
1	1	!0x55AA	0xXXXX	1	No
0	1	0xXXXX	0x55AA	1	No
0	1	0xXXXX	!0x55AA	1	No

¹ BOOTCFG[0:1] bits are located in the SIU_RSR.

² EXTM bit is located in the EBI_MCR.

13.4.2.6.4 External Boot Default

The SIU latches the boot default value in the SIU_RSR BOOTCFG[0:1] bits if and only if $\overline{\text{RSTCFG}}$ is negated. Censorship logic sets the boot default value before the SIU latches the value to external-with-external-master access disabled (EXTM = 0) if the lower half of the censorship control word equals 0xFFFF or 0x0000. Otherwise, censorship logic sets the boot default value to internal flash.

13.4.3 Flash Memory Array: Stop Mode

Stop mode is entered by setting the FLASH_MCR[STOP] bit. The FLASH_MCR[STOP] bit cannot be written when FLASH_MCR[PGM] = 1 or FLASH_MCR[ERS] = 1. In stop mode all DC current sources in the flash module are disabled. Stop mode is exited by clearing the FLASH_MCR[STOP] bit.

Accessing the flash memory array when STOP is asserted results in an error response from the flash BIU to the system bus. Memory array accesses must not be attempted until the flash transitions out of stop mode.

13.4.4 Flash Memory Array: Reset

A reset is the highest priority operation for the flash and terminates all other operations.

The flash uses reset to initialize register and status bits to their default reset values. If the flash is executing a program or erase operation and a reset is issued, the operation is aborted and the flash disables the high voltage logic without damage to the high voltage circuits. Reset aborts all operations and forces the flash into normal operating mode ready to receive accesses. FLASH_MCR[DONE] is set to 1 at the exit of reset.

After reset is negated, register accesses can be performed, although registers that require updating from shadow information, or other inputs, cannot read updated values until flash exits reset. FLASH_MCR[DONE] can be polled to determine if reset has been exited.

13.5 Document Revision History

Table 13-18. Changes Between MPC5565RM Revisions 0.1 and 1

In the Overview section, made this change:

- From: "...and a 256-bit read data interface to flash memory. If enabled, the Flash BIU contains a two-entry, 256-bit prefetch buffer and a prefetch controller that prefetches sequential lines of data from the flash array into the buffer. Prefetch buffer hits allow no-wait responses. Normal flash array accesses are registered in the FBIU and are forwarded to the system bus on the following cycle, . . ."
- To: "...and a 256-bit read data interface from the flash memory array. If enabled, the Flash BIU contains a two-entry prefetch buffer, each entry containing 256 bits of data, and an associated controller that prefetches sequential lines of data from the flash array into the buffer. Prefetch buffer hits support zero-wait responses. Normal flash array accesses (i.e. those accesses that do not hit in the prefetch buffers) are registered in the FBIU and are forwarded to the system bus on the following cycle,..."

Section 13.1.3, "Features": Changed 2nd bulleted list, fourth bullet to "Page program size of 256 bits allows programming from one to four consecutive 64-bit doublewords within a page."

Chapter 14

Internal Static RAM (SRAM)

14.1 Introduction

The SRAM provides 80 KB of general-purpose system SRAM. The first 32-KB of SRAM is powered by a separate power supply pin for standby operation. [Figure 14-1](#) shows the internal SRAM block diagram.

Figure 14-1. Internal SRAM Block Diagram

The SRAM controller has these features:

- Read/write accesses can map to SRAM from any master
- 32 KB with a separate power source for standby operation
- Byte, halfword, word, and doubleword addressable
- Single-bit correction and double-bit error detection

14.2 SRAM Operating Modes

[Table 14-1](#) lists and describes the SRAM operating modes.

Table 14-1. SRAM Operating Modes

Mode	Description
Normal (functional)	Allows reads and writes of SRAM.
Standby	Preserves the 32 KB of standby memory when the 1.5 V power drops below the level of V_{STBY} . Updates to standby SRAM are inhibited during system reset or during standby mode.

14.3 External Signal Description

The external signal for SRAM is the V_{STBY} RAM power supply. If the standby feature of the SRAM is not used, tie the V_{STBY} pin to V_{SS} .

14.4 Register Memory Map

The SRAM occupies 80 KB of memory starting at the base address as shown in [Table 14-2](#).

Table 14-2. SRAM Memory Map

Address	Register Name	Register Description	Size
Base (0x4000_0000)	—	SRAM powered by V _{STBY}	32 KB
Base + 0x8000	—	48-KB RAM	48 KB

The internal SRAM has no registers. Registers for the SRAM ECC are located in the ECSM (refer to [Chapter 8, “Error Correction Status Module \(ECSM\),”](#) for more information).

14.5 Functional Description

ECC checks are performed during the read portion of an SRAM ECC read/write (R/W) operation, and ECC calculations are performed during the write portion of a read/write (R/W) operation. Because the ECC bits can contain random data after the device is powered on, you must initialize the SRAM by executing 64-bit write instructions to the entire SRAM. For more information, refer to [Section 14.7, “Initialization and Application Information.”](#)

14.6 SRAM ECC Mechanism

The SRAM ECC detects the following conditions and produces the following results:

- Detects and corrects all 1-bit errors
- Detects and flags all 2-bit errors as non-correctable errors
- Detects 72-bit reads (64-bit data bus plus the 8-bit ECC) that return all zeros or all ones, asserts an error indicator on the bus cycle, and sets the error flag

SRAM does not detect all errors greater than 2 bits.

Internal SRAM write operations are performed on the following byte boundaries:

- 1 byte (0:7 bits)
- 2 bytes (0:15 bits)
- 4 bytes or 1 word (0:31 bits)
- 8 bytes or 2 words (0:63 bits)

If the entire 64 data bits are written to SRAM, no read operation is performed and the ECC is calculated across the 64-bit data bus. The 8-bit ECC is appended to the data segment and written to SRAM.

If the write operation is less than the entire 64-bit data width (1-, 2-, or 4-byte segment), the following occurs:

1. The ECC mechanism checks the entire 64-bit data bus for errors, detecting and either correcting or flagging errors.
2. The write data bytes (1-, 2-, or 4-byte segment) are merged with the corrected 64 bits on the data bus.

3. The ECC is then calculated on the resulting 64 bits formed in the previous step.
4. The 8-bit ECC result is appended to the 64 bits from the data bus, and the 72-bit value is then written to SRAM.

14.6.1 Access Timing

The system bus is a two-stage pipelined bus, which makes the timing of any access dependent on the access during the previous clock. [Table 14-3](#) lists the various combinations of read and write operations to SRAM and the number of wait states used for the each operation. The table columns contain the following information:

- Current operation Lists the type of SRAM operation executing currently
- Previous operation Lists the valid types of SRAM operations that can precede the current SRAM operation (valid operation during the preceding clock)
- Wait states Lists the number of wait states (bus clocks) the operation requires which depends on the combination of the current and previous operation

Table 14-3. Number of Wait States Required for SRAM Operations

	Current Operation	Previous Operation	Number of Wait States Required
Read Operation	Read	Idle	1
		Pipelined read	
		Burst read	
		64-bit write	2
		8-, 16-, or 32-bit write	0 (read from the same address)
			1 (read from a different address)
	Pipelined read	Read	0
	Burst read	Idle	1,0,0,0
		Pipelined read	
		Burst read	
		64-bit write	2,0,0,0
		8-, 16-, or 32-bit write	0,0,0,0 (read from the same address)
1,0,0,0 (read from a different address)			

Table 14-3. Number of Wait States Required for SRAM Operations (continued)

	Current Operation	Previous Operation	Number of Wait States Required
Write Operation	8-, 16-, or 32-bit write	Idle	1
		Read	
		Pipelined 8-, 16-, or 32-bit write	2
		64-bit write	
		8-, 16-, or 32-bit write	0 (write to the same address)
	Pipelined 8-, 16-, or 32-bit write	8-, 16-, or 32-bit write	0
	64-bit write	Idle	0
		64-bit write	
		Read	
	64-bit burst write	Idle	0,0,0,0
		64-bit write	
		Read	

14.6.2 Reset Effects on SRAM Accesses

If a reset event asserts during a read or write operation to SRAM, the completion of that access depends on the cycle at which the reset occurs. Data read from or written to SRAM before the reset event occurred is retained, and no other address locations are accessed or changed.

NOTE

Standby memory can contain the previous data values if a reset occurs while cache is running in copy back mode.

14.7 Initialization and Application Information

To use the SRAM, the ECC must check all bits that require initialization after power on. Use a 64-bit cache-inhibited write to each SRAM location in the application initialization code to initialize the SRAM array. All writes must specify an even number of registers performed on 64-bit word-aligned boundaries. If the write is not the entire 64-bits (8-, 16-, or 32-bits), a read / modify / write operation is generated that checks the ECC value upon the read. Refer to [Section 14.6, “SRAM ECC Mechanism.”](#)

NOTE

You *must* initialize SRAM, even if the application does not use ECC reporting.

14.7.1 Example Code

To initialize SRAM correctly, use the store multiple word (**stmw**) instruction to implement 64-bit writes to all SRAM locations. The **stmw** instruction concatenates two 32-bit registers to implement a single 64-bit write.

The following example code illustrates the use of the **stmw** instruction to initialize the SRAM ECC bits.

```
init_RAM:
lis      r11,0x4000      # base address of the SRAM, 64-bit word aligned
ori      r11,r11,0      # not needed for this address but could be for others
li       r12,640        # loop counter to get all of SRAM;
                        # 80k/4 bytes/32 GPRs = 640
mtctr   r12
init_ram_loop:
stmw    r0,0(r11)       # write all 32 GPRs to SRAM
addi    r11,r11,128     # inc the ram ptr; 32 GPRs * 4 bytes = 128
bdnz   init_ram_loop   # loop for 80k of SRAM
blr                                           # done
```

Table 14-4. Changes Between MPC5565RM Revisions 0.1 and 1

No changes since the last release.

Chapter 15

Boot Assist Module (BAM)

15.1 Introduction

This chapter describes the boot assist module (BAM).

15.1.1 Overview

The BAM contains the MCU boot program code. The BAM control block is connected to peripheral bridge B and occupies the last 16 KB of the MCU memory space. The BAM program supports several booting modes:

- Internal flash
- External memory without bus arbitration
- Serial boot using an eSCI interface
- FlexCAN interfaces

The BAM program is executed by the e200z6 core just after the MCU reset. Depending on the boot mode, the program initializes the minimum MCU resources to start application code execution.

Figure 15-1 is a block diagram of the BAM.

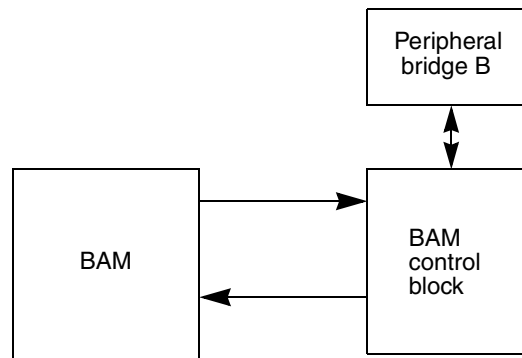

Figure 15-1. BAM Block Diagram

15.1.2 Features

The BAM program provides the following features:

- Initial e200z6 core MMU setup with minimum address translation for all internal MCU resources and external memory address space
- Locate and detect application boot code
- Automatic switch to serial boot mode if internal or external flash is not initialized or invalid
- Programmable 64-bit password protection for serial boot mode
- Boot application code from internal flash module and external memory without arbitration
- Serial boot loads the application boot code from a FlexCAN or eSCI bus into internal SRAM
- Censorship protection for internal flash module
- Enable the e200z6 core watchdog timer
- Configurable memory map for use with the classic PowerPC Book E code or Freescale VLE code

15.1.3 Modes of Operation

15.1.3.1 Normal Mode

In normal operation, the BAM responds to all read requests within its address space. The BAM program is executed following the negation of reset.

15.1.3.2 Debug Mode

The BAM program is not executed when the MCU comes out of reset in OnCE debug mode. Use the development tool to configure and initialize the MCU before accessing the MCU resources.

15.1.3.3 Internal Boot Mode

Use internal boot mode to boot from internal flash memory. Configuration information, initialization, and boot code are kept in internal flash. The BAM program must complete the boot process before application code can enable the external bus interface.

15.1.3.4 External Boot Modes

Use external boot mode when the boot code and configuration information are located in external memory that is connected to the EBI. Do not select external boot mode for devices without an external bus.

15.1.3.5 Serial Boot Mode

This mode of operation can load a user program into internal SRAM using either the eSCI or FlexCAN serial interface, then to execute the downloaded program. The program can then control the downloading of data, as well as erasing and programming the internal or external flash memory.

Serial boot mode downloads:

- 64-bit password
- 32-bit start address
- 32-bit download consisting of 1-bit VLE flag (most significant bit) followed by a 31-bit length field containing the number of bytes to receive (download length)

Set the VLE flag to 1 for devices that support variable length encoding and must run in VLE mode. When the VLE flag is set, the BAM programs the external bus interface (EBI), RAM, and the flash memory map unit (MMU) TLB entries 1, 2, and 3 with the VLE attribute.

Clear the VLE bit to 0 for devices that use the PowerPC Book E or Power Architecture instruction set mode.

15.2 Memory Map

The BAM has 16 KB of memory, from 0xFFFF_C000 through 0xFFFF_FFFF, which is divided into four 4 KB segments, each containing a copy of the BAM program code. The BAM code resides in the 4-KB memory segment beginning at 0xFFFF_F000. A copy of the BAM code resides in the three preceding 4-KB segment, as shown in [Table 15-1](#). The BAM program executes from the reset vector at address 0xFFFF_FFFC.

[Table 15-1](#) shows the addresses for the BAM code in the memory map.

Table 15-1. BAM Memory Map

Address	Description
0xFFFF_C000–0xFFFF_CFFF	BAM program mirrored
0xFFFF_D000–0xFFFF_DFFF	BAM program mirrored
0xFFFF_E000–0xFFFF_EFFF	BAM program mirrored
0xFFFF_F000–0xFFFF_FFFF	BAM program

15.3 Functional Description

15.3.1 BAM Program Resources

The BAM program initializes and uses the following MCU resources:

- BOOTCFG field in the reset status register (SIU_RSR) to determine the boot option
- Address and contents of the reset configuration halfword (RCHW), which contains the address and configuration options for the boot code. Refer to [Chapter 4, “Reset,”](#) for information about the RCHW.
- DISNEX bit in the SIU_CCR register to determine if the Nexus port is enabled
- MMU allows core access to MCU internal resources and the EBI
- EBI registers and external bus pads, when using external boot modes
- FlexCAN A, eSCI A and their pads, when using serial boot mode

- eDMA during serial boot mode

15.3.2 BAM Program Operation

The MCU core accesses the BAM after \overline{RSTOUT} negates and before the application program executes.

The BAM program configures the e200z6 core MMU access for all MCU internal resources and external memory, as shown in Table 15-2. The memory map configuration is the same for internal flash boot mode.

Table 15-2. MMU Configuration for Internal Flash Boot

TLB Entry	Region	Attributes	Logical Base Address	Physical Base Address	Size
0	Peripheral bridge B and BAM	<ul style="list-style-type: none"> • Cache inhibited • Guarded • Big endian • Global PID 	0xFFFF0_0000	0xFFFF0_0000	1 MB
1	Internal flash	<ul style="list-style-type: none"> • Cache enabled • Not guarded • Big endian • Global PID 	0x0000_0000	0x0000_0000	16 MB
2	EBI	<ul style="list-style-type: none"> • Cache enabled • Not guarded • Big endian • Global PID 	0x2000_0000	0x0000_0000	16 MB
3	Internal SRAM	<ul style="list-style-type: none"> • Cache inhibited • Not guarded • Big endian • Global PID 	0x4000_0000	0x4000_0000	256 KB
4	Peripheral bridge A	<ul style="list-style-type: none"> • Cache inhibited • Guarded • Big endian • Global PID 	0xC3F0_0000	0xC3F0_0000	1 MB

MMU maps the logical addresses to the same physical addresses for all modules except for the external bus interface (EBI). The logical EBI addresses are mapped to physical addresses in internal flash memory. This allows code developed to run from external memory to run from internal flash memory.

The BAM program reads the following data and determines the boot mode for the boot sequence:

- BOOTCFG[0:1] located in the reset status register (SIU_RSR)
- Censorship control field located at 0x00FF_FDE0 in the shadow row of internal flash
- Serial boot control field located at 0x00FF_FDE2 in the shadow row of internal flash

The boot mode determines the following:

- Enables or disables internal flash memory
- Enables or disables the Nexus port
- Compares the password received in serial boot mode to a preset public password or a programmable password located in internal flash

Table 15-3 summarizes the different boot modes.

Table 15-3. Boot Modes

BOOTCFG [0:1]	Censorship Control 0x00FF_FDE0	Serial Boot Control 0x00FF_FDE2	Boot Mode Name	Internal Flash State	Nexus State	Serial Password
00	!0x55AA ¹	Any value	Internal—Censored	Enabled	Disabled	Flash
	0x55AA		Internal—Public	Enabled	Enabled	Public
01	Any value	0x55AA	Serial—Flash password	Enabled	Disabled	Flash
		!0x55AA	Serial—Public password	Disabled	Enabled	Public
10	!0x55AA	Any value	External—No arbitration—Censored	Disabled	Enabled	Public
	0x55AA		External—No arbitration—Public	Enabled	Enabled	Public
11	Invalid value					

¹ '!' = 'NOT,' as in !0x55AA, which means all values except 0x55AA. Do not use 0x0000 or 0xFFFF for the value of the censorship control or serial boot control words.

The 32-bit censorship word, which contains the censorship control and serial boot control fields, is read and interpreted during the boot process. Its value is used in conjunction with the BOOTCFG[0:1] values to enable or disable the internal flash memory and the Nexus interface. The censorship word is programmed at the factory to contain 0x55AA_55AA, which uses a password in internal flash to activate serial boot mode for an uncensored (public) device.

The censorship word starts at address 0x00FF_FDE0 and contains a 16-bit censorship control field [0:15] and a 16-bit serial boot control field [16:31]. The factory default settings are shown in Figure 15-2:

Figure 15-2. Censorship Word

Boot Assist Module (BAM)

The BAM program reads the DISNEX bit to determine which of the following passwords to compare with the serial password received in serial boot mode:

- Public password (64-bit constant value of 0xFEED_FACE_CAFE_BEEF); or
- Flash password (64-bit value in the shadow row of internal flash at address 0x00FF_FDD8).

Serial boot flash password starts at address 0x00FF_FDD8:

Address: 0x00FF_FDD8													Value: 0xFEED			
MSB	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Hex value	B				E				E				F			

Figure 15-3. Serial Boot Flash Password

The BAM program continues to make specific initialization in one of the four boot modes.

15.3.2.1 Internal Boot Mode

When the BAM detects internal flash boot mode, a bus error exception handler is invoked to handle corrupt data from internal flash memory and avoid a bus error. The BAM program reads up to six addresses in internal flash to find a valid 16-bit reset configuration halfword (RCHW). If a valid RCHW is read, the BAM program sets the e200z6 watchdog timer enable bit RCHW[WTE]. If a valid RCHW is not read, the BAM program proceeds to serial boot mode.

15.3.2.1.1 Finding Reset Configuration Halfword

A valid RCHW is a 16-bit value that contains a constant 8-bit boot identifier and configuration bits (refer to [Section 4.4.3.5.1, “Reset Configuration Halfword Definition”](#)). The RCHW is the first halfword in one of the six low address flash blocks as shown in [Table 15-4](#).

Table 15-4. Low Address Space (LAS) Block Memory Addresses

Block	Address
0	0x0000_0000
1	0x0000_4000
2	0x0001_0000
3	0x0001_C000
4	0x0002_0000
5	0x0003_0000

If the BAM fails to find a valid RCHW, it assumes the flash is erased or corrupt and switches to serial-boot

If the value in RCHW is valid, the watchdog timer is enabled by setting the RCHW[WTE] bit, the BAM program fetches the reset vector from `BOOT_BLOCK_ADDRESS + 0x0004`, and branches to the reset boot vector. The application must have a valid instruction at the reset boot vector address.

`BOOT_BLOCK_ADDRESS + 0x0000_0004`

Figure 15-4. Reset Boot Vector

If the watchdog timer is enabled, the watchdog timeout is set to 2.5×2^{17} system clock periods.

15.3.2.2 External Boot Modes

Use external boot mode to boot an application from an external asynchronous memory device that is connected to the EBI. External boot mode is controlled by $\overline{CS}[0]$.

15.3.2.2.1 External Boot MMU Configuration

As shown in [Table 15-5](#), the BAM program sets up two MMU regions differently than in internal flash boot mode (refer to [Table 15-2](#)). The internal flash logical addresses are mapped to the physical addresses of the EBI.

Table 15-5. MMU Configuration for External Boot Mode

TLB Entry	Region	Attributes	Logical Base Address	Physical Base Address	Size
1	Internal flash memory	<ul style="list-style-type: none"> • Cache enabled • Not guarded • Big endian • Global PID 	0x0000_0000	0x2000_0000	16 MB
2	EBI	<ul style="list-style-type: none"> • Cache enabled • Not guarded • Big endian • Global PID 	0x2000_0000	0x2000_0000	16 MB

This allows code, written to run from internal flash memory, to execute from external memory.

15.3.2.2.2 Single Bus Master

External boot with no arbitration mode is used for single-master systems where the MCU is the only bus master, therefore no arbitration of the external bus is necessary. Refer to [Section 15.3.2.2.3, “Configure the EBI for External Boot—Single Master with no Arbitration.”](#)

The boot modes are specified by the BOOTCFG[0:1] value. Refer to the following sections for more information:

[Section 12.5.5.2, “Arbitration with No Arb Pins \(Master/Slave only\)”](#)

[Section 12.4.2.10, “Bus Operation in External Master Mode”](#)

[Section 12.5.5, “Dual-MCU Operation with Reduced Pinout MCUs”](#) to implement a system with master and slave peripherals for a device with no arbitration pins.

15.3.2.2.3 Configure the EBI for External Boot—Single Master with no Arbitration

The BAM program configures:

- Chip select $\overline{CS}[0]$ as a 16-bit port starting at base address 0x2000_0000 with:
 - no burst
 - 15 wait states
 - 8 MB
- EBI for no external master (clears EXTM bit)
- Enables the EBI for normal operation
- Configures the following EBI signals:
 - ADDR[8:31]
 - DATA[0:15]
 - $\overline{WE}[0]$
 - \overline{OE}
 - \overline{TS}
 - $\overline{CS}[0]$

15.3.2.2.4 Read the Reset Configuration Halfword

The BAM program reads the first location in external memory, i.e address 0x2000_0000, for a valid reset configuration halfword (RCHW, refer to [Figure 15-4](#)). If the BAM program does not find a valid RCHW, it uses serial boot mode.

If the BAM program finds a valid RCHW, the data pins are configured and the $\overline{CS}[0]$ port size according to the RCHW[PS0] bit and the e200z6 core watchdog according to the RCHW[WTE] bit. According to RCHW[VLE], the MMU boots using PowerPC Book E code or Freescale VLE code. The watchdog timeout is set to 2.5×2^{17} system clock periods. Then the BAM program reads the reset vector ([Figure 15-4](#)) from the address 0x2000_0004 and branches to that reset vector address, starting application program execution.

15.3.2.3 Serial Boot Mode Operation

Serial boot mode downloads:

- 64-bit password
- 32-bit start address
- 32-bit download consisting of 1-bit VLE flag followed by a 31-bit length field

Set the VLE flag to 1 for devices that support variable length encoding and must run in VLE mode. When the VLE flag is set, the BAM programs the external bus interface (EBI), RAM, and the flash memory map unit (MMU) TLB entries 1, 2, and 3 with the VLE attribute.

Clear the VLE bit to 0 for devices that use the PowerPC Book E or Power Architecture instruction set mode.

In serial boot operating mode, the following occurs:

- FlexCAN A and the eSCI A GPIO signals are reconfigured
- Unused message buffers in FlexCAN A are used as scratch pad RAM
- MMU is setup
- Watchdog timer is enabled

No exceptions are used in serial boot mode.

15.3.2.3.1 Serial Boot Mode MMU and EBI Configuration

The BAM program sets up the MMU for all peripheral and memory regions in one of two different modes and sets up the EBI in one of three different modes; depending on how serial boot mode was entered.

If serial boot mode is entered directly by choosing the mode with the BOOTCFG signals, or was entered indirectly from internal boot mode because no valid RCHW was found, then the MMU is configured the same way as for internal boot mode. The EBI is disabled and all bus pins function as GPIO.

If serial boot mode is entered indirectly from external boot/single-master because no valid RCHW was found, then the MMU and EBI are configured the for an external boot mode with a 16-bit data bus.

Refer to [Table 15-3](#) and [Table 15-5](#) for more information.

15.3.2.3.2 Serial Boot Mode FlexCAN and eSCI Configuration

In serial boot mode, the BAM program configures FlexCAN A and eSCI A to receive messages. The CNRXA and RXDA signals are configured as inputs to the FlexCAN and eSCI modules. The CNTXA signal is configured as an output from the FlexCAN module. The TXDA signal of the eSCI A remains configured as GPIO input. The BAM program writes 0x0000_0000_0000_0000 to the e200z6 core timebase registers (TB), and enables the e200z6 core watchdog timer to use the system clock and to cause a reset after a time-out period of 3×2^{28} system clock cycles.

Refer to [Table 15-7](#) for examples of time out periods.

In serial boot mode the FlexCAN controller is configured to operate at a baud (bit) rate equal to the system clock frequency divided by 60 with one message buffer (MB) using the standard 11-bit identifier format detailed in the CAN 2.0A specification.

Refer to [Section 21.4.5.4, “Protocol Timing,”](#) for information on FlexCAN bit rate generation.

Coming out of reset, the default system clock is 1.5 times the crystal frequency. The baud rate with PLL enabled is equal to the crystal frequency divided by 40.

Refer to [Chapter 11, “Frequency Modulated Phase Locked Loop and System Clocks \(FMPLL\),”](#) for more information. [Table 15-6](#) shows FlexCAN operation at reset.

Table 15-6. BAM FlexCAN Frequency at Reset (FMPLL Enabled out of Reset)

FMPLL Clock Mode	System Clock Frequency (f_{sys}) after Reset	Serial Boot Mode Frequency ¹ (FlexCAN Baud Rate)
Crystal reference mode or External reference mode	1.5 x crystal reference frequency ($f_{ref_crystal}$) ²	Crystal reference frequency divided by 40
Dual controller mode	2 x EXTCLK	EXTCLK divided by 30

¹ Serial boot mode frequency is set in software as the system clock frequency divided by 60.

² Crystal reference frequency is set at 8–20 MHz.

The BAM ignores the following errors:

- Bit 1 errors
- Bit 0 errors
- Acknowledge errors
- Cyclic redundancy code errors
- Form errors
- Stuffing errors
- TX error counter errors
- Rx error counter errors

All data received, regardless of errors, is echoed out on the CNTXA signal.

NOTE

The host computer must compare the ‘echoed data’ to the sent data and restart the process if an error is detected.

Refer to [Figure 15-5](#) for details of FlexCAN bit timing.

1 time quanta = 5 system clock periods = 3 1/3 crystal clock periods (with PLL enabled)

Figure 15-5. FlexCAN Bit Timing

The eSCI is configured for 1 start bit, 8 data bits, no parity and 1 stop bit and to operate at a baud rate equal to the system clock divided by 1250. Refer to [Table 15-7](#) for examples of baud rates.

The BAM ignores the following eSCI errors:

- Overrun errors
- Noise errors
- Framing errors
- Parity errors

All data received is assumed to be good and is echoed out on the TXD signal. It is the responsibility of the host computer to compare the echoes with the sent data and restart the process if an error is detected.

Table 15-7. Serial Boot Mode—Baud Rate and Watchdog Summary

Crystal Frequency (MHz)	System Clock Frequency (MHz)	SCI Baud Rate (baud)	FlexCAN Baud Rate (baud)	Watchdog Timeout Period (seconds)
$f_{\text{ref_crystal}}$	$f_{\text{sys}} = 1.5 \times f_{\text{ref_crystal}}$	$f_{\text{sys}} / 1250$	$f_{\text{sys}} / 60$	$2.5 \times 2^{27} / f_{\text{sys}}$
8	12	9600	200 K	67.1
12	18	14400	300 K	44.7
16	24	19200	400 K	33.6
20	30	24000	500 K	26.8

Upon receiving a valid FlexCAN message with an ID equal to 0x011 that contains 8 data bytes, or a valid eSCI message, the BAM uses a serial boot submode: FlexCAN serial boot mode, or eSCI serial boot mode.

In FlexCAN serial boot mode, the eSCI A signal RXDA reverts to GPIO input. All data is downloaded on the FlexCAN bus and eSCI messages are ignored.

In eSCI serial boot mode, the FlexCAN A signals CNRXA and CNTXA revert to GPIO inputs and the TXDA signal is configured as an output. All data is downloaded on the eSCI bus and FlexCAN messages are ignored.

Table 15-8. FlexCAN and eSCI Reset Configuration for FlexCAN and eSCI Boot

Pin Label	Reset Function	Initial Serial Boot Mode	Serial Boot Mode after Receiving a Valid	
			FlexCAN Message	eSCI Message
CNTXA	GPIO	CNTXA	CNTXA	GPIO
CNRXA	GPIO	CNRXA	CNRXA	GPIO
TXDA	GPIO	GPIO	GPIO	TXDA
RXDA	GPIO	RXDA	GPIO	RXDA

Table 15-9. FlexCAN and eSCI Reset Pin Configuration

Pins	I/O	Weak Pullup State	Hysteresis	Driver Configuration	Slew Rate	Input Buffer Enable
CNTXA_TXDA	Output	Enabled Up	—	Push/pull	Medium	N
CNRXA_RXDA	Input	Enabled Up	Y	—	—	—
GPIO	Input	Enabled Up	Y	—	—	—

15.3.2.3.3 Download Process for FlexCAN Serial Boot Mode

The download process contains the following steps:

1. Download the 64-bit password.
2. Download the start address, VLE flag, and the number of data bytes to download.
3. Download the data.
4. Execute the boot code from the start address.

Each step of the process must complete before the next step starts.

1. Download the 64-bit password.

The host computer must send a FlexCAN message with ID = 0x011 that contains the 64-bit serial download password. FlexCAN messages with other IDs or fewer bytes of data are ignored. When a valid message is received, the BAM transmits a FlexCAN message with ID = 0x001 that contains the data received. The host must not send a second FlexCAN message until it receives the echo of the first message. A FlexCAN message sent before the echo is received is ignored.

The 64-bit password is validated to ensure that none of the four 16-bit halfwords have a value of 0x0000 or 0xFFFF, which are invalid passwords. A valid password must have at least one 0 and one 1 in each halfword lane.

The BAM program then reads the disable Nexus bit [DISNEX] in the SIU_CCR register to determine the censorship status of the MCU. If Nexus is disabled, the MCU is censored and the password is compared to a password stored in the shadow row in internal flash memory.

If Nexus is enabled, the MCU is not censored or booting from external flash and the password is compared to the constant value = 0xFEED_FACE_CAFE_BEEF.

If the password fails any validity tests, the MCU stops responding to all stimulus. To repeat boot operation, the MCU needs to be reset by external reset or by watchdog. If the password is valid, the BAM program refreshes the e200z6 watchdog timer and the next step in the protocol can be performed.

2. Download the start address, VLE bit, and the download size.

The host computer must send a FlexCAN message with an ID = 0x012 that contains:

- 32-bit start address in internal SRAM indicating where to store the succeeding data in memory;
- 32-bit number containing a 1-bit variable length encoded (VLE) flag followed by a 31-bit length field that contains the number of data bytes to receive and store in memory before switching to execute the code just loaded.

The start address is expected on a 32-bit word boundary, therefore the least significant 2 bits of the address are ignored. FlexCAN messages with other IDs or fewer data bytes are ignored.

Set the VLE bit in the serial download data (most significant bit in the LENGTH word) if the code to download uses VLE instructions.

When a valid message is received, the BAM transmits a FlexCAN message with an ID = 0x002 that contains the received data. The host computer must not send another FlexCAN message until it receives the echo from the previous message. A FlexCAN message sent before the echo is received is ignored.

3. Download the data.

The host computer must send a succession of FlexCAN messages with ID = 0x013 that contains raw binary data (the data length is variable). Each data byte received is stored in MCU memory, starting at the address specified in the previous step and incrementing through memory until the number of data bytes received and stored in memory matches the number specified in the previous step. FlexCAN messages with ID values other than 0x013 are ignored.

When a valid message is received, the BAM transmits a FlexCAN message with an ID = 0x003 that contains the data received. The host computer must not send another FlexCAN message until it receives the echo from the previous message. A FlexCAN message sent before the echo is received is ignored.

NOTE

Internal SRAM is protected by 64-bit error correction (ECC) hardware. All writes to uninitialized internal SRAM must be 64-bits wide, or an ECC error occurs. The BAM buffers 8 bytes of downloaded data before executing a single 64-bit write. Only internal SRAM supports 64-bit writes. Downloading data to other RAM causes errors.

If the start address of the downloaded data is not at an 8-byte boundary, the BAM writes 0x00 to the memory locations from the preceding 8-byte boundary to the start address (maximum 4 bytes). The BAM also writes 0x00 to all memory locations from the last byte of data downloaded to the following 8-byte boundary (maximum 7 bytes).

4. Execute code.

The BAM waits for the last FlexCAN message transmission to complete. Then the FlexCAN controller is disabled. CNTXA and CNRXA become GPIO inputs. The BAM branches to the starting address of the downloaded code, as specified in step 2.

NOTE

The code that downloads and executes must:

- Periodically refresh the e200z6 watchdog timer; or
- Change the timeout period to a value that does not cause resets during normal operation.

Table 15-10. FlexCAN Serial Boot Mode Download Process

Step	Host Message Sent	MCU Response Message	Action
1	FlexCAN ID = 0x011 + 64-bit password	FlexCAN ID = 0x001 + 64-bit password	Password checked for validity and compared against stored password. e200z6 watchdog timer is refreshed if the password check is successful.
2	FlexCAN ID = 0x012 + 32-bit store address + 32-bit number of bytes	FlexCAN ID = 0x002 + 32-bit store address + 32-bit number of bytes	The load address and the number of bytes to download are stored for future use.
3	FlexCAN ID = 0x013 + 8 to 64 bits of raw binary data	FlexCAN ID = 0x003 + 8 to 64 bits of raw binary data	Each data byte received is written to MCU memory, starting at the address specified in the previous step and incrementing until the number of data bytes received and stored matches the number of bytes to download and store (specified in step 2).
4	None	None	The BAM program returns I/O pins and the FlexCAN module to their reset state, then branches to the start address of the stored data (specified in step 2).

15.3.2.3.4 eSCI Serial Boot Mode Download Process

The eSCI serial boot mode download process contains the following steps:

1. Download the 64-bit password.
2. Download the start address, VLE flag, and the number of data bytes to download.
3. Download the data.

4. Execute the code from start address.

Each step in the following process must complete before the next step starts. The eSCI operates in half duplex mode where the host sends a byte of data, then waits for the echo back from the MCU before proceeding with the next byte. Bytes sent from the host before the previous echo from the MCU is received are ignored.

1. Download the 64-bit password.

The first 8 bytes of eSCI data the host computer sends must contain the 64-bit serial download password. For each valid eSCI message received, the BAM transmits the same data on the eSCI A TXDA signal.

The received 64-bit password is checked for validity. It is checked to ensure that none of the 4 x 16-bit halfwords are illegal passwords (0x0000 or 0xFFFF). A password must have at least one 0 and one 1 in each halfword to qualify as legal.

The BAM program then checks the censorship status of the MCU by checking the DISNEX bit in the SIU_CCR. If Nexus is disabled, the MCU is considered censored and the password is compared with a password stored in the shadow row of internal flash memory.

If Nexus is enabled, the MCU is not censored or is booting from external flash and the password is compared to the constant value of 0xFEED_FACE_CAFE_BEEF.

If the password fails a validity test, the MCU stops responding to all stimulus. To repeat the boot operation, assert the $\overline{\text{RESET}}$ signal or wait for the watchdog timer to reset the MCU. If the password is valid, the BAM refreshes the e200z6 watchdog timer and proceeds to step 2.

2. Download the start address, VLE bit, and the download size.

The host computer must send the next eight bytes of eSCI data that contains:

- 32-bit start address in internal SRAM indicating where to store the succeeding data in memory;
- 32-bit number containing a 1-bit variable length encoded (VLE) flag followed by a 31-bit length field that contains the number of data bytes to receive and store in memory before switching to execute the code just loaded.

The start address is normally located on a word boundary (4-bytes), therefore the least significant 2 bits of the address are ignored. For each valid eSCI message received, the BAM transmits the same data on the eSCI A TXDA signal.

Set the VLE bit in the serial download data (most significant bit in the LENGTH word) if the code to download uses VLE instructions.

3. Download the data.

The host computer must then send a succession of eSCI messages, each containing raw binary data. Each byte of data received is stored in the MCU's memory, starting at the address specified in the previous step and incrementing through memory until the number of data bytes received and stored in memory matches the number specified in the previous step. For each valid eSCI message received, the BAM transmits the same data on the TXDA signal.

NOTE

Internal SRAM is protected by 64-bit wide error correction coding hardware (ECC). All writes to uninitialized internal SRAM must be 64 bits wide, or an ECC error occurs. The BAM buffers download data until 8-bytes are received, and then executes a single 64-bit wide write. Only internal SRAM supports 64-bit writes. Downloading data to RAM other than internal SRAM causes errors.

If the start address of the downloaded data is not on an 8-byte boundary, the BAM writes 0x00 beginning at the preceding 8-byte boundary memory location to the start address (4 byte maximum). The BAM also writes 0x00 to all memory locations from the last data byte downloaded to the following 8-byte boundary (7 byte maximum).

4. Execute the code.

The BAM waits for the last eSCI message transmission to complete and then disables the eSCI. TXDA and RXDA revert to general-purpose inputs. The BAM branches to the starting address where the downloaded code is stored (specified in step 2) and executes the code.

NOTE

The code that downloads and executes must periodically refresh the e200z6 watchdog timer or change the timeout period to a value that does not cause resets during normal operation.

Table 15-11. eSCI Serial Boot Mode Download Process

Step	Host Sent Message	BAM Response Message	Action
1	64-bit password MSB first	64-bit password	Password checked for validity and compared against stored password. e200z6 watchdog timer is refreshed if the password check is successful
2	32-bit store address + 32-bit number of bytes MSB first	32-bit store address + 32-bit number of bytes	Load address and size of download are stored for future use
3	8 bits of raw binary data	8 bits of raw binary data	Each byte of data received is stored in MCU memory, starting at the address specified in the previous step and incrementing until the number of data bytes received and stored matches the number of data bytes specified in the preceding step.
4	None	None	The BAM returns I/O pins and the eSCI module to their reset state, except it asserts ESCI_A_CR2[MDIS] instead of negates. Then the BAM branches to the starting address of the stored data specified in step 2.

15.3.3 Interrupts

No interrupts are generated or enabled by the BAM.

15.4 Revision History

The following tables list the changes to the preliminary content in this chapter:

Table 15-12. Changes Between MPC5565RM Revisions 0.1 and 1

<p>Added Table 15-6 “BAM FlexCAN Frequency at Reset (FMPLL Enabled out of Reset) to Serial Boot Mode FlexCAN and eSCI Configuration section.</p>
<p>Added the location and register for the VLE bit by adding Table 15-6 and Figure 15-4.</p>
<p>Removed Table 15-6 and Figure 15-4 because it doesn’t apply to this device--it only applies to the MPC5516.</p>
<p>Section 15.1.3.5, “Serial Boot Mode,” Added the following: Serial boot mode downloads:</p> <ul style="list-style-type: none"> • 64-bit password • 32-bit start address • 32-bit download consisting of 1-bit VLE flag (most significant bit) followed by a 31-bit length field containing the number of bytes to receive (download length) <p>Set the VLE flag to 1 for devices that support variable length encoding and must run in VLE mode. When the VLE flag is set, the BAM programs the external bus interface (EBI), RAM, and the flash memory map unit (MMU) TLB entries 1, 2, and 3 with the VLE attribute.</p> <p>Clear the VLE bit to 0 for devices that use the PowerPC Book E or Power Architecture instruction set mode.</p>
<p>Section 15.3.2.3.3, “Download Process for FlexCAN Serial Boot Mode,” Changed step 2 of the first bulleted list to: 2. Download the start address, VLE flag, and the number of data bytes to download.</p> <p>Rewrote beginning of step 2 from the second bulleted list to read: 2. Download the start address, VLE bit, and the download size. The host computer must send a FlexCAN message with an ID = 0x012 that contains:</p> <ul style="list-style-type: none"> • 32-bit start address in internal SRAM indicating where to store the succeeding data in memory; • 32-bit number containing a 1-bit variable length encoded (VLE) flag followed by a 31-bit length field that contains the number of data bytes to receive and store in memory before switching to execute the code just loaded. <p>Added: Set the VLE bit in the serial download data (most significant bit in the LENGTH word) if the code to download uses VLE instructions.</p>
<p>Section 15.3.2.3.4, “eSCI Serial Boot Mode Download Process,” Changed step 2 of the first bulleted list to: 2. Download the start address, VLE flag, and the number of data bytes to download.</p> <p>Rewrote beginning of step 2 from the second bulleted list to read: 2. Download the start address, VLE bit, and the download size. The host computer must send the next eight bytes of eSCI data that contains:</p> <ul style="list-style-type: none"> • 32-bit start address in internal SRAM indicating where to store the succeeding data in memory; • 32-bit number containing a 1-bit variable length encoded (VLE) flag followed by a 31-bit length field that contains the number of data bytes to receive and store in memory before switching to execute the code just loaded. <p>Added: Set the VLE bit in the serial download data (most significant bit in the LENGTH word) if the code to download uses VLE instructions.</p>

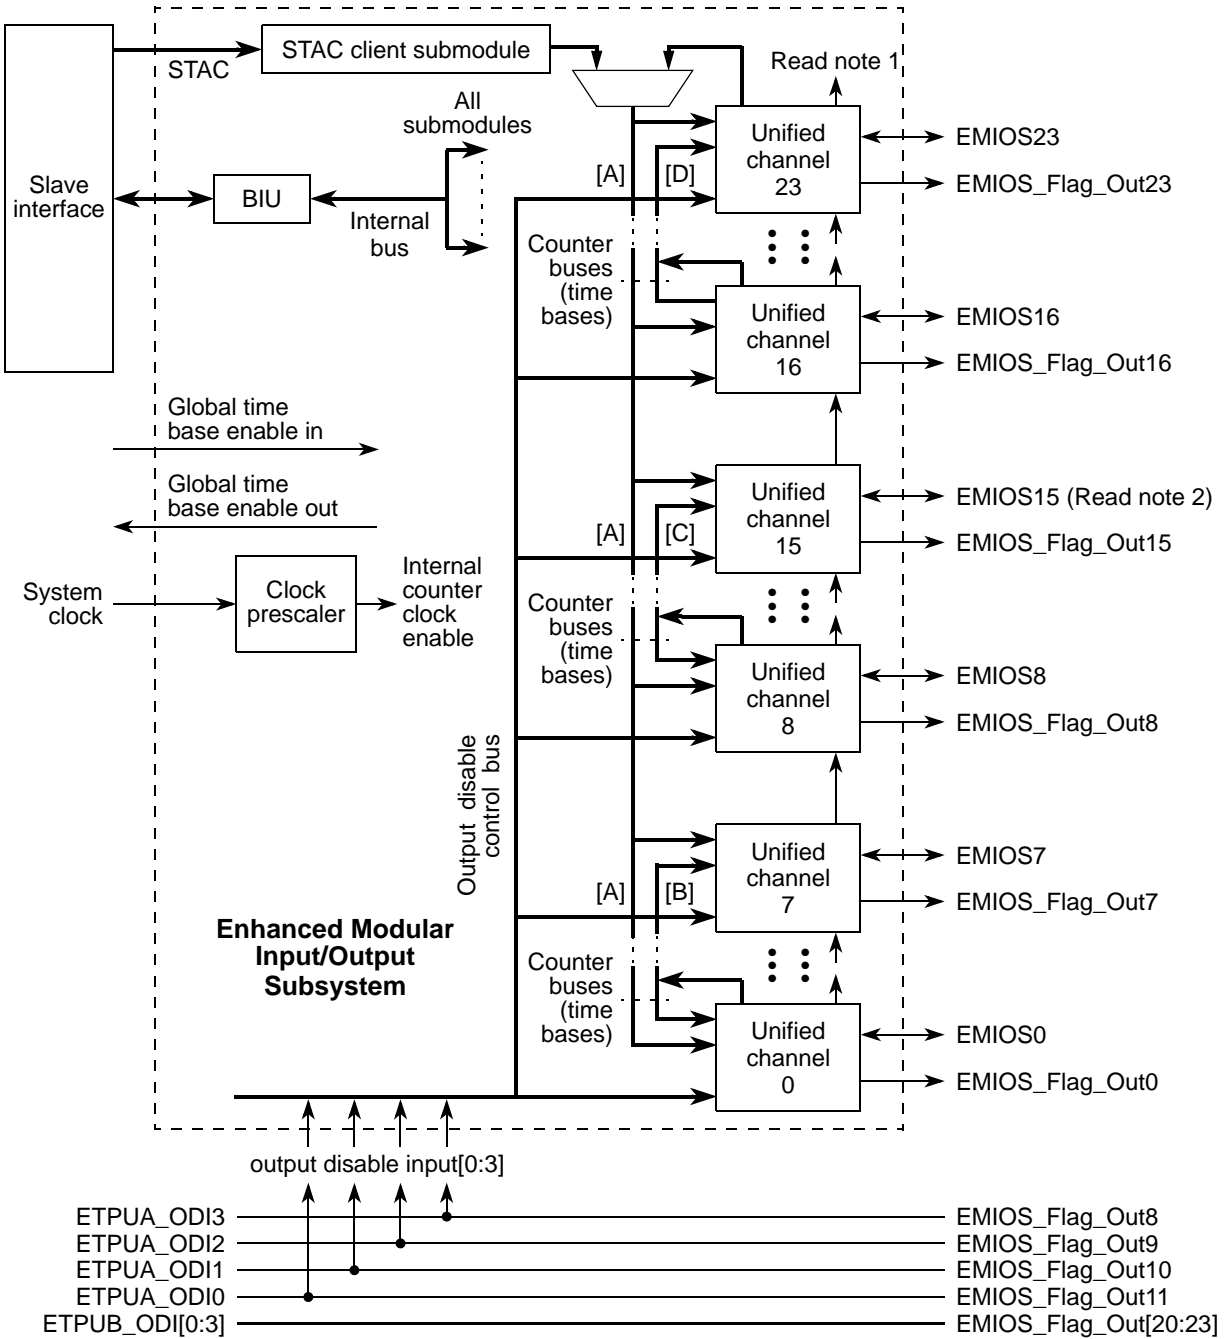

Chapter 16

Enhanced Modular Input/Output Subsystem (eMIOS)

16.1 Introduction

This chapter describes the enhanced modular input/output subsystem (eMIOS) which can generate or measure timed events.

Figure 16-1 shows the block diagram of the eMIOS.

Note 1: Connection between UC[n-1] and UCn necessary to implement QDEC mode.

Note 2: On channels 12–15, there is no input from EMIOS[12:15], only from the DSPI module.

Figure 16-1. eMIOS Block Diagram

16.1.1 Overview

The eMIOS builds on the MIOS concept by using a unified channel module that provides a superset of the functionality of all the individual MIOS channels, while providing a consistent user interface. This allows more flexibility as each unified channel can be programmed for different functions.

16.1.2 Features

- 24 unified channels
- Unified channels features
 - 24-bit registers for captured/match values
 - 24-bit internal counter
 - Internal prescaler
 - Dedicated output pin for buffer direction control
 - Selectable time base
 - Can generate its own time base
- Four 24-bit wide counter buses
 - Counter bus A can be driven by unified channel 23 or by the STAC bus.
 - Counter bus B, C, and D are driven by unified channels 0, 8, and 16, respectively.
 - Counter bus A can be shared among all unified channels. UCs 0 to 7 can share counter bus A and B, UCs 8 to 15 can share counter bus A and C, and UCs 16 to 23 can share counter buses A and D.
- One global prescaler
- Shared time bases through the counter buses
- Synchronization among internal and external time bases
- Shadow FLAG register
- State of module can be frozen for debug purposes
- DMA request capability for some channels
- Motor control capability

16.1.3 eMIOS Operating Modes

The eMIOS has the following operating modes:

Table 16-1. eMIOS Operating Modes

Mode	Description
User	User mode is the normal operating mode. When EMIOS_MCR[FRZ] = 0, and EMIOS_CCR[FREN] = 0, the eMIOS is in user mode.
Debug	Debug mode is individually programmed for each channel. When entering this mode, the UC registers' contents are frozen, but remain available for read and write access through the slave interface. After leaving debug mode, all counters that were frozen upon debug mode entry resume at the point where they were frozen. In debug mode, all clocks are running and all registers are accessible; thus, this mode is not intended for power saving, but for use during software debugging.
Freeze	Freeze mode enables the eMIOS to freeze the registers of the unified channels when debug mode is requested at the MCU level. While in freeze mode, the eMIOS continues to operate to allow the MCU access to the unified channels' registers. The unified channel remains frozen until the EMIOS_MCR[FRZ] bit is cleared to zero, the MCU exits debug mode, or a unified channel's EMIOS_CCR[FREN] bit is cleared.

16.1.3.1 Unified Channel Modes

The unified channels can be configured to operate in the following modes:

- General purpose input/output
- Single action input capture
- Single action output compare
- Input pulse-width measurement
- Input period measurement
- Double action output compare
- Pulse/edge accumulation
- Pulse/edge counting
- Quadrature decode
- Windowed programmable time accumulation
- Modulus counter, normal
- Modulus counter, buffered
- Output pulse-width and frequency modulation, normal
- Output pulse-width and frequency modulation, buffered
- Center-aligned output pulse-width modulation with dead time insertion, normal
- Center-aligned output pulse-width modulation with dead time insertion, buffered
- Output pulse-width modulation, normal
- Output pulse-width modulation, buffered

These modes are described in [Section 16.4.4.4, “Unified Channels Operating Modes.”](#)

16.2 External Signal Description

Each unified channel has one input and one output signal connected to the channel's I/O pin. Refer to the SIU, eTPU, and DSPI sections for details about the connection to pads and other modules.

The internal *output disable input* signals 0-3 (refer to [Table 16-3](#)) are provided to implement the output disable feature needed for motor control. They are connected to EMIOS_Flag_Out signals according to [Section 16.2.1.1, "Output Disable Input—eMIOS Output Disable Input Signals."](#)

16.2.1 External Signals

When configured as an input, EMIOS n is synchronized and filtered by the programmable input filter (PIF). The output of the PIF is then used by the channel logic and is available to be read by the MCU through the UCIN bit of the EMIOS_CSR n .

When configured as an output, EMIOS n is a registered output and is available for reading by the MCU through the UCOUT bit of the EMIOS_CSR n .

Table 16-2. External Signals

Signal	Direction	Function	Reset State
EMIOS[0:11, 16:23]	Input	eMIOS Unified Channel n input	—
EMIOS[0:23]	Output	eMIOS Unified Channel n output	0 / Hi-Z ¹

¹ A value of 0 refers to the reset value of the signal. Hi-Z refers to the state of the external pin if a tri-state output buffer is controlled by the corresponding eMIOS signal.

16.2.1.1 Output Disable Input—eMIOS Output Disable Input Signals

Output disable inputs to both the eMIOS and the eTPU modules are connected to EMIOS_Flag_Out*n* signals according to [Table 16-3](#).

Table 16-3. eMIOS Output Disable Input Signals

eMIOS Channel ¹	eMIOS Output Disable Input Signal ²	eTPU Output Disable Input Signal ³
EMIOS_Flag_Out8	Output disable input 3	ETPUA_ODI3
EMIOS_Flag_Out9	Output disable input 2	ETPUA_ODI2
EMIOS_Flag_Out10	Output disable input 1	ETPUA_ODI1
EMIOS_Flag_Out11	Output disable input 0	ETPUA_ODI0
EMIOS_Flag_Out20	—	ETPUB_ODI0
EMIOS_Flag_Out21	—	ETPUB_ODI1
EMIOS_Flag_Out22	—	ETPUB_ODI2
EMIOS_Flag_Out23	—	ETPUB_ODI3

¹ All other EMIOS_Flag_Out*n* output signals are not connected.

² Each of the four internal eMIOS *output disable input* signals can be programmed to disable the output of any eMIOS channel if that channel has selected output disable capability by the setting of its EMIOS_CCR*n*[ODIS] bit, and by specifying the output disable input in its EMIOS_CCR*n*[ODISSL] field.

³ ETPU*x*_ODI*y* input signals disable outputs for eTPU engine *x*, channels (*y**8) through (*y**8+7). Refer to the ETPU chapter for more details.

16.3 Memory Map/Register Definition

Addresses of unified channel (UC) registers are specified as offsets from the channel’s base address, otherwise the eMIOS base address is used as reference.

The overall address map organization is shown in [Table 16-4](#).

Table 16-4. eMIOS Memory Map

Address	Register Name	Register Description	Bits
Base (0xC3FA_0000)	EMIOS_MCR	Module configuration register	32
Base + 0x0004	EMIOS_GFR	Global flag register	32
Base + 0x0008	EMIOS_OUDR	Output update disable register	32
Base + 0x000C–Base + 0x001F	—	Reserved	—
Base + 0x0020	UC0	Unified channel 0 registers	256
Base + 0x0040	UC1	Unified channel 1 registers	256
Base + 0x0060	UC2	Unified channel 2 registers	256

Table 16-4. eMIOS Memory Map (continued)

Address	Register Name	Register Description	Bits
Base + 0x0080	UC3	Unified channel 3 registers	256
Base + 0x00A0	UC4	Unified channel 4 registers	256
Base + 0x00C0	UC5	Unified channel 5 registers	256
Base + 0x00E0	UC6	Unified channel 6 registers	256
Base + 0x0100	UC7	Unified channel 7 registers	256
Base + 0x0120	UC8	Unified channel 8 registers	256
Base + 0x0140	UC9	Unified channel 9 registers	256
Base + 0x0160	UC10	Unified channel 10 registers	256
Base + 0x0180	UC11	Unified channel 11 registers	256

16.3.1 Register Description

All registers are 32-bit wide. This section describes the eMIOS with 24 unified channels supporting 24-bit wide data.

16.3.1.1 eMIOS Module Configuration Register (EMIOS_MCR)

EMIOS_MCR contains global control bits for the eMIOS module.

Address: Base + 0x0000

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	MDIS	FRZ	GTBE	ETB	GPREN	0	0	0	0	0	0	SRV

Figure 16-2. eMIOS Module Configuration Register (EMIOS_MCR)

The following table describes the fields in the eMIOS module configuration register:

Table 16-6. EMIOS_MCR Field Descriptions

Field	Description
0	Reserved. This bit is readable and writable, but has no effect.
1 MDIS	Module disable. Puts the eMIOS in low power mode. The MDIS bit is used to stop the clock of the module, except the access to registers EMIOS_MCR and EMIOS_OUDR. 0 Clock is running 1 Enter low power mode
2 FRZ	Freeze. Enables the eMIOS to freeze the registers in the unified channels when debug mode is requested at the MCU level. Set the FREN bit in each unified channel to enter freeze mode. While in freeze mode, the eMIOS continues to operate to allow the MCU access to the unified channels registers. The unified channel remains frozen until: <ul style="list-style-type: none"> FRZ bit is cleared to zero; or, MCU exits debug mode; or, Unified channel FREN bit is cleared 0 Allows unified channels to continue to operate when device enters debug mode and the EMIOS_CCRn[FREN] bit is set 1 Stops unified channels operation when in debug mode and the EMIOS_CCRn[FREN] bit is set
3 GTBE ¹	Global time base enable. Used to export a global time base enable from the module and provide a method to start time bases of several modules simultaneously. 0 Global time base enable out signal negated 1 Global time base enable out signal asserted Note: The global time base enable input signal controls the internal counters. When asserted, internal counters are enabled. When negated, internal counters disabled.

Table 16-6. EMIOS_MCR Field Descriptions (continued)

Field	Description																
4 ETB	External time base. Selects the time base source that drives counter bus [A]. 0 Unified channel 23 drives counter bus [A] 1 STAC drives counter bus[A] Note: If ETB is set to select STAC as the counter bus[A] source, the GTBE must be set to enable the STAC to counter bus[A]. See Section 16.4.2, “STAC Client Submodule” and the shared time and angle clock (STAC) bus interface section and the STAC bus configuration register (ETPU_REDCR) section of the eTPU chapter for more information about the STAC.																
5 GPREN	Global prescaler enable. Enables the prescaler counter. 0 Prescaler disabled (no clock) and prescaler counter is cleared 1 Prescaler enabled																
6–11	Reserved.																
12–15 SRV[0:3]	Server time slot. Selects the address of a specific STAC server to which the STAC client submodule is assigned (refer to Section 16.4.2, “STAC Client Submodule,” for details) 0000 eTPU engine A, TCR1 0001 eTPU engine B, TCR1 0010 eTPU engine A, TCR2 0011 eTPU engine B, TCR2 0100–1111 reserved																
16–23 GPRE[0:7]	Global prescaler. Selects the clock divider value for the global prescaler, as shown here: <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>GPRE[0:7]</th> <th>Divide Ratio</th> </tr> </thead> <tbody> <tr> <td>00000000</td> <td>1</td> </tr> <tr> <td>00000001</td> <td>2</td> </tr> <tr> <td>.</td> <td>.</td> </tr> <tr> <td>.</td> <td>.</td> </tr> <tr> <td>.</td> <td>.</td> </tr> <tr> <td>.</td> <td>.</td> </tr> <tr> <td>11111111</td> <td>256</td> </tr> </tbody> </table>	GPRE[0:7]	Divide Ratio	00000000	1	00000001	2	11111111	256

00000001	2																
.	.																
.	.																
.	.																
.	.																
11111111	256																
24–31	Reserved.																

¹ The GTBE signal is an inter-module signal, not an external pin on the device.

16.3.1.2 eMIOS Global Flag Register (EMIOS_GFR)

The EMIOS_GFR is a read-only register that groups the FLAG bits from all channels. This organization improves interrupt handling on simpler devices. These bits are mirrors of the FLAG bits of each channel register (EMIOS_CSR) and flag bits in those channel registers cannot be cleared by accessing this ‘mirror’ register.

Address: Base + 0x0004

Access: R/O

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 16-3. eMIOS Global Flag Register (EMIOS_GFR)

16.3.1.3 eMIOS Output Update Disable Register (EMIOS_OUDR)

The EMIOS_OUDR serves to disable transfers from the A2 to the A1 channel registers and from the B2 to the B1 channel registers when values are written to these registers, and the channel is running in modulus counter (MC) mode or an output mode.

Address: Base + 0x0008

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 16-4. eMIOS Output Update Disable Register (EMIOS_OUDR)

The following table describes the fields in the eMIOS output update disable register:

Table 16-7. EMIOS_OUDR Field Descriptions

Field	Description
0–7	Reserved.
8–31 OU n	Channel n output update disable. When running in MC mode or an output mode, values are written to registers A2 and B2. OU n bits are used to disable transfers from registers A2 to A1 and B2 to B1. Each bit controls one channel. 0 Transfer enabled. Depending on the operating mode, transfer occurs immediately or in the next period. Unless stated otherwise, transfer occurs immediately. 1 Transfers disabled

16.3.1.4 eMIOS Channel A Data Register (EMIOS_CADR_n)

Depending on the mode of operation, internal registers A1 or A2, used for matches and captures, can be assigned to address EMIOS_CADR_n. Both A1 and A2 are cleared by reset. Table 16-8 summarizes the EMIOS_CADR_n writing and reading accesses for all operating modes.

Refer to Section 16.4.4.4, “Unified Channels Operating Modes” for more information.

Figure 16-5. eMIOS Channel A Data Register (EMIOS_CADR_n)

16.3.1.5 eMIOS Channel B Data Register (EMIOS_CBDR_n)

Depending on the mode of operation, internal registers B1 or B2 can be assigned to address EMIOS_CBDR_n. Both B1 and B2 are cleared by reset. Table 16-8 summarizes the EMIOS_CBDR_n writing and reading accesses for all operating modes.

Refer to Section 16.4.4.4, “Unified Channels Operating Modes” for more information.

NOTE

The EMIOS_CBDR_n must not be read speculatively. For future compatibility, the TLB entry covering the EMIOS_CBDR_n must be configured to be guarded.

OPWM – buffered	A2	A1	B2	B1	—

¹ In these modes, the register EMIOS_CBDR_n is not used, but B2 can be accessed.

16.3.1.6 eMIOS Channel Counter Register (EMIOS_CCNTR n)

The EMIOS_CCNTR n contains the value of the internal counter. When GPIO mode is selected or the channel is frozen, the EMIOS_CCNTR n is readable and writable. For all others modes, the EMIOS_CCNTR n is a read-only register. When entering some operating modes, this register is automatically cleared.

Refer to [Section 16.4.4.4, “Unified Channels Operating Modes,”](#) for details.

Address: UC n Base + 0x0008

Figure 16-7. eMIOS Channel Counter Register (EMIOS_CCNTR n)

16.3.1.7 eMIOS Channel Control Register (EMIOS_CCR n)

The eMIOS_CCR n enables the setting of several control parameters for a unified channel. Among these controls are the setting of a channel prescaler, channel mode selection, input trigger sensitivity and filtering, interrupt and DMA request enabling, and output mode control.

25–31 MODE	Mode selection. Selects the mode of operation of the unified channel, as shown in Table 16-10 .

The following table lists the binary values for the unified channel operating modes used in the eMIOS channel control register:

Table 16-10. Binary Values for Unified Channel Operating Modes

MODE[0:6]	Unified Channel Operating Modes
0000000	General purpose input/output mode (input)
0000001	General purpose input/output mode (output)
0000010	Single action input capture
0000011	Single action output compare
0000100	Input pulse-width measurement
0000101	Input period measurement
0000110	Double-action output compare (with FLAG set on the second match)
0000111	Double-action output compare (with FLAG set on both match)
0001000	Pulse and edge accumulation (continuous)

Table 16-10. Binary Values for Unified Channel Operating Modes (continued)

MODE[0:6]	Unified Channel Operating Modes
0001001	Pulse and edge accumulation (single shot)
0001010	Pulse and edge counting (continuous)
0001011	Pulse and edge counting (single shot)
0001100	Quadrature decode (for count and direction encoders type)
0001101	Quadrature decode (for phase_A and phase_B encoders type)
0001110	Windowed programmable time accumulation
0001111	Reserved
0010000	Modulus counter. Up counter, internal clock source.
0010001	Modulus counter. Up counter, external clock source.
0010010–0010011	Reserved
0010100	Modulus counter. Up/down counter, no change in counter direction upon match of input counter and register B1, internal clock source.
0010101	Modulus counter. Up/down counter, no change in counter direction upon match of input counter and register B1, external clock source.
0010110	Modulus counter. Up/down counter, change in counter direction upon match of input counter and register B1 and sets the FLAG, internal clock source.
0010111	Modulus counter. Up/down counter, change in counter direction upon match of input counter and register B1 and sets the FLAG, external clock source.
0011000	Output pulse-width and frequency modulation. FLAG set at match of internal counter and comparator B, immediate update.
0011001	Output pulse-width and frequency modulation. FLAG set at match of internal counter and comparator B, next period update.
0011010	Output pulse-width and frequency modulation. FLAG set at match of internal counter and comparator A or comparator B, immediate update.
0011011	Output pulse-width and frequency modulation. FLAG set at match of internal counter and comparator A or comparator B, next period update.
0011100	Center-aligned output pulse-width modulation. FLAG set in trailing edge, trailing edge dead-time.
0011101	Center-aligned output pulse-width modulation. FLAG set in trailing edge, leading edge dead-time.
0011110	Center-aligned output pulse-width modulation. FLAG set in both edges, trailing edge dead-time.
0011111	Center-aligned output pulse-width modulation. FLAG set in both edges, leading edge dead-time.
0100000	Output pulse-width modulation. FLAG set at match of internal counter and comparator B, immediate update.
0100001	Output pulse-width modulation. FLAG set at match of internal counter and comparator B, next period update.
0100010	Output pulse-width modulation. FLAG set at match of internal counter and comparator A or comparator B, immediate update.

Table 16-10. Binary Values for Unified Channel Operating Modes (continued)

MODE[0:6]	Unified Channel Operating Modes
0100011	Output pulse-width modulation. FLAG set at match of internal counter and comparator A or comparator B, next period update.
1100100–1111111	Reserved
1010000	Modulus up counter, buffered, internal clock
1010001	Modulus up counter, buffered, external clock
1010010–1010001	Reserved
1010100	Modulus up/down counter, buffered. FLAG set on one event, internal clock.
1010101	Modulus up/down counter, buffered. FLAG set on one event, external clock.
1010110	Modulus up/down counter, buffered. FLAG set on both events, internal clock.
1010111	Modulus up/down counter, buffered. FLAG set on both events, external clock.
1011000	Output pulse-width and frequency modulation, buffered. FLAG set at match of internal counter and comparator B.
1011001	Reserved
1011010	Output pulse-width and frequency modulation, buffered. FLAG set at match of internal counter and comparator A or comparator B.
1011011	Reserved
1011100	Center-aligned output pulse-width modulation, buffered. FLAG set on trailing edge, trailing edge dead-time.
1011101	Center-aligned output pulse-width modulation, buffered. FLAG set on trailing edge, leading edge dead-time.
1011110	Center-aligned output pulse-width modulation, buffered. FLAG set on both edges, trailing edge dead-time.
1011111	Center-aligned output pulse-width modulation, buffered. FLAG set on both edges, leading edge dead-time.
1100000	Output pulse-width modulation, buffered. FLAG set on second match.
1100001	Reserved
1100010	Output pulse-width modulation, buffered. FLAG set on both matches.

16.3.1.8 eMIOS Channel Status Register (EMIOS_CSRn)

EMIOS_CSRn reflects the status of the UC input/output signals and the overflow condition of the internal counter, as well as the occurrence of a trigger event.

Address: UCn Base + 0x0010

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	OVR	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W	w1c															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	OVFL	0	0	0	0	0	0	0	0	0	0	0	0	UCIN	UCOUT	FLAG
W	w1c															w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 16-9. eMIOS Channel Status Register (EMIOS_CSRn)

The following table describes the fields in the eMIOS channel status register:

Table 16-11. EMIOS_CSRn Field Descriptions

Field	Description
0 OVR	Overflow. Indicates a FLAG was generated when the FLAG bit was set to 1. To clear the OVR bit: write 1 to clear the bit to 0, or clear the FLAG bit to 0, which also clears the OVR bit. 0 Overflow has not occurred 1 Overflow has occurred
1–15	Reserved.
16 OVFL	Overflow. Indicates that an overflow occurred in the internal counter. OVFL is cleared by writing a 1 to it. 0 No overflow 1 An overflow had occurred
17–28	Reserved.
29 UCIN	Unified channel input pin. Reflects the input pin state after being filtered and synchronized.
30 UCOUT	Unified channel output pin. The UCOUT bit reflects the output pin state.
31 FLAG	FLAG. Set when an input capture or a match event in the comparators occurs. Write a 1 to clear this bit to 0. 0 FLAG cleared 1 FLAG set event has occurred Note: When EMIOS_CCR[DMA] bit is set, the FLAG bit is cleared by the eDMA controller.

16.3.1.9 eMIOS Alternate Address Register (EMIOS_ALTAn)

The EMIOS_ALTAn register provides an alternate read-only address to access channel registers in PEC and WPTA modes. If EMIOS_ALTAn is used it is possible to access the A2 register in the PEC and WPTA modes. The EMIOS_ALTAn address register does not implement coherency mechanisms such as the blocking of B register updates after the A register is read.

Table 16-8, “EMIOS_CADRn, EMIOS_CBDRn, and EMIOS_ALTAn Value Assignments,” shows the internal registers accessed by address EMIOS_ALTAn in each one of the channel operation modes.

Figure 16-10. eMIOS Alternate Address Register (EMIOS_ALTAn)

The following table describes the field in the eMOIS alternate address register:

Table 16-12. EMIOS_ALTAn Field Descriptions

Field	Description
0–7	Reserved.
8–31 ALTA	Alternate address. Set when an alternate address is provided for accessing both the A1 and A2 channel registers. 0 Access only A1 register 1 Access both A1 and A2 registers

16.4 Functional Description

The eMIOS provides independent channels (UC) that can be configured and accessed by the MCU. Four time bases can be shared by the channels through four counter buses and each unified channel can generate its own time base. Optionally, the counter A bus can be driven by an external time base from the eTPU imported through the STAC interface.

NOTE

Counter bus A can be driven by unified channel 23 or by the STAC bus.
Counter bus B, C, and D are driven by unified channels 0, 8, and 16, respectively. Counter bus A can be shared among all unified channels. UCs 0 to 7 can share counter bus A and B, UCs 8 to 15 can share counter bus A and C, and UCs 16 to 23 can share counter buses A and D.

The four components of the eMIOS module are:

- Bus interface unit
- STAC client submodule
- Global clock prescaler
- Unified channels and their modes of operation

16.4.1 Bus Interface Unit (BIU)

The bus interface unit provides the interface between the internal bus and the slave interface, allowing communication among all submodules and the slave interface. The BIU allows 8-, 16-, and 32-bit accesses. They are performed over a 32-bit data bus in a single cycle clock.

16.4.1.1 Effect of Freeze on the BIU

When the FRZ bit in the EMIOS_MCR is set and the module is in debug mode, the operation of the BIU is not affected.

16.4.2 STAC Client Submodule

The shared time and angle count (STAC) bus provides access to one external time base, imported from the STAC bus to the eMIOS unified channels. The eTPU module's time bases and angle count can be exported and/or imported through the STAC client submodule interface. Time bases and/or angle information of either eTPU engine can be exported to the other eTPU engine and to the eMIOS module, which is only a STAC client. There are restrictions on engine export/import targets: one engine cannot export from or import to itself, nor can it import time base and/or angle count if in angle mode.

The device's STAC server identification assignment is shown in [Table 16-13](#). The time slot assignment is fixed, so only time bases running at system clock divided by four or slower can be integrally exported. The STAC client submodule runs with the system clock, and its time slot timing is synchronized with the eTPU timing on reset. The time slot sequence is 0-1-2-3, such that they alternate between engines one and two.

Table 16-13. STAC Client Submodule Server Slot Assignment

Engine	Time Base	Server ID
1	TCR1	0
1	TCR2	2
2	TCR1	1
2	TCR2	3

Figure 16-11 provides a block diagram for the STAC client submodule.

Figure 16-11. STAC Client Submodule Block Diagram

Bits SRV[0:3] in register EMIOS_MCR, selects the time slot of the STAC output bus. Figure 16-12 shows a timing diagram for the STAC client submodule.

- NOTES:
1. Maximum of 16 time slots (TS_n)
 2. The SRV bits capture TS[01]

Figure 16-12. Timing Diagram for the STAC Bus and STAC Client Submodule Output

Every time the selected time slot changes, the STAC client submodule output is updated.

16.4.2.1 Effect of Freeze on the STAC Client Submodule

When the FRZ bit in the EMIOS_MCR is set and the module is in debug mode, the operation of the STAC client submodule is not affected; that is, there is no freeze function in this submodule.

16.4.3 Global Clock Prescaler Submodule (GCP)

The global trace prescaler divides the system clock to generate a clock for the unified channels. The system clock is prescaled by the value defined according to the GPRE[0:7] bits in the EMIOS_MCR. The output is clocked every time the counter overflows. Counting is enabled by setting EMIOS_MCR[GPREN]. The counter can be stopped at any time by clearing this bit, thereby stopping the internal counter in all the unified channels.

NOTE

When the FRZ bit in the EMIOS_MCR is set and the module is in debug mode, the operation of the GCP submodule is not affected; there is no freeze function in this submodule.

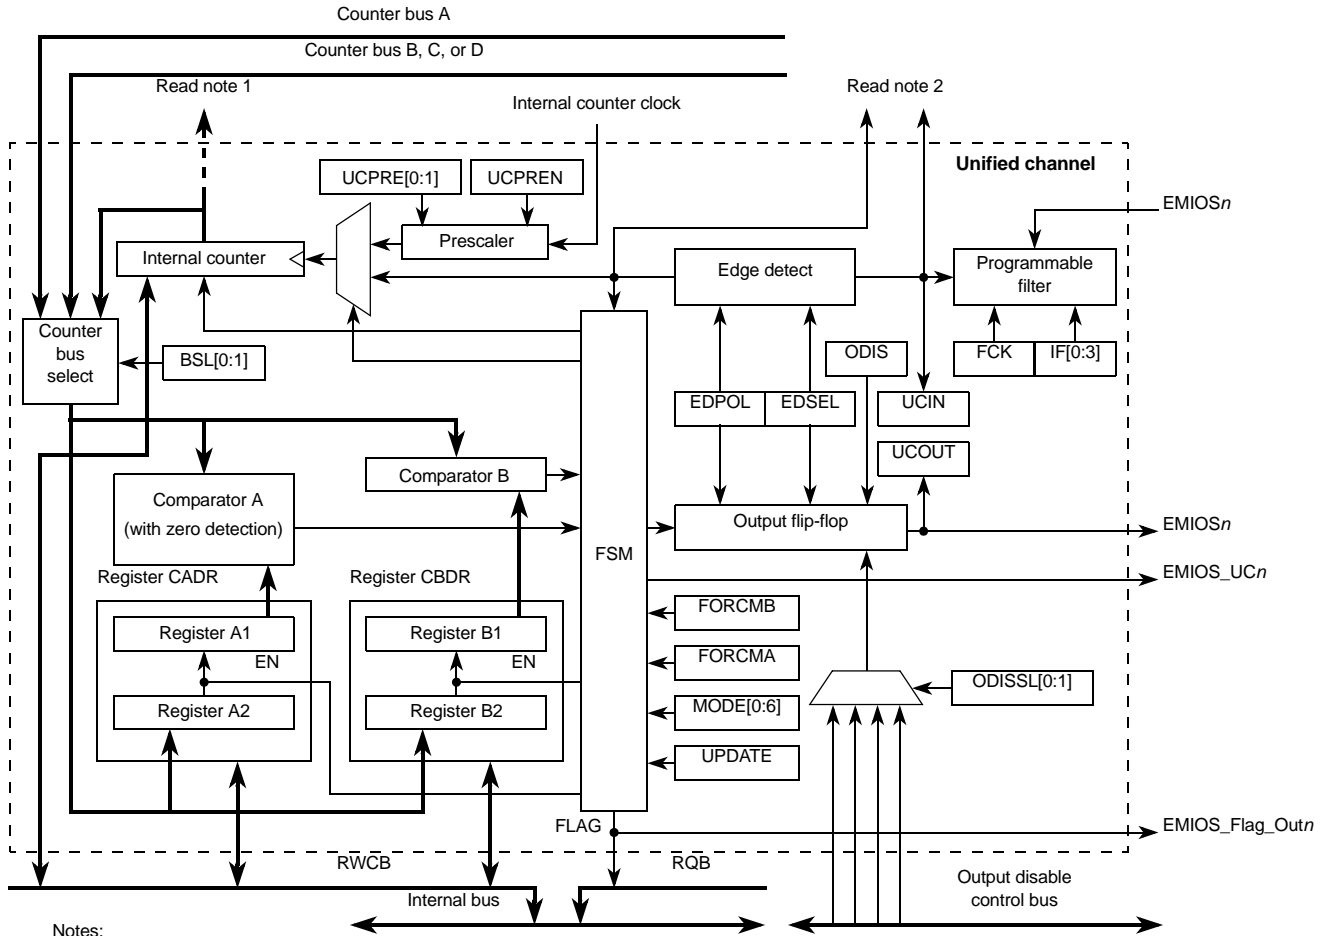

16.4.4 Unified Channel (UC)

Figure 16-13 shows the unified channel block diagram. Each unified channel consists of the following:

- Counter bus select that sets the time base used for all timing functions by the channel
- Programmable clock prescaler
- Two double buffered data registers A and B that allow up to two input capture and/or output compare events to occur before software intervention is needed.
- Two comparators (equal only) A and B that compare the selected counter bus with the value in the data registers
- Internal counter for use as a local time base or to count input events
- Programmable input filter that ensures that only valid pin transitions are received by a channel
- Programmable input edge-detector that detects rising, falling, or both edges
- Output flip-flop that holds the logic level applied to the output pin
- eMIOS status and control registers
- Output disable input selector that assigns an output-disabled input signal for use as the unified channel output disable
- Control state machine (FSM)

The major components and functions of the unified channels are discussed in [Section 16.4.4.1, “Programmable Input Filter \(PIF\)”](#) through [Section 16.4.4.4, “Unified Channels Operating Modes.”](#)

Enhanced Modular Input/Output Subsystem (eMIOS)

Notes:

- Counter bus A can be driven by either the STAC bus or channel 23. Refer to EMIOS_MCR[ETB]. Channel 0 drives counter bus B, channel 8 drives counter bus C and channel 16 drives counter bus D. Counter bus B can be selected as the counter for channels 0-7, counter bus C for channels 8-15, and counter bus D for channels 16-23. Refer to Figure 1-1 and EMIOS_CCRn[BS].
- Goes to the finite state machine of the UC[n-1]. These signals are used for QDEC mode.

Figure 16-13. Unified Channel Block Diagram

16.4.4.1 Programmable Input Filter (PIF)

The PIF ensures that only valid input pin transitions are received by the unified channel edge detector. A block diagram of the PIF is shown in [Figure 16-14](#).

The PIF is a 5-bit programmable up counter that is incremented by the selected clock source, according to bits IF[0:3] in EMIOS_CCR n . The clock source is selected by the EMIOS_CCR n [FCK] bit.

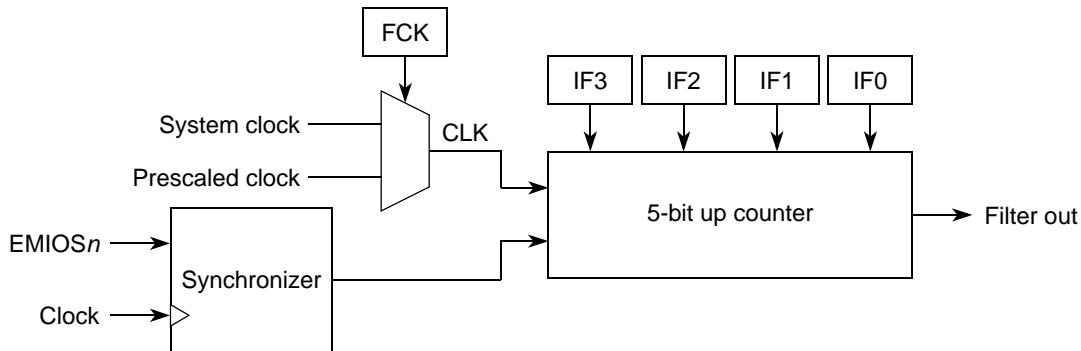

Figure 16-14. Programmable Input Filter Submodule Diagram

The input signal is synchronized by the system clock. When a state change occurs in this signal, the 5-bit counter starts counting up. As long as the new state is stable on the pin, the counter continues incrementing. If a counter overflow occurs, the new pin value is validated. In this case, it is transmitted as a pulse edge to the edge detector. If the opposite edge appears on the pin before validation (overflow), the counter is reset. At the next synchronized pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch, and it is not passed on to the edge detector. A timing diagram of the input filter is shown in [Figure 16-15](#).

Figure 16-15. Programmable Input Filter Example

16.4.4.2 Clock Prescaler (CP)

A unified channel has a clock prescaler (CP) that divides the global clock prescaler (refer to [Section 16.4.3, “Global Clock Prescaler Submodule \(GCP\)”](#)) output signal to generate a clock enable for the internal counter of the unified channel. It is a programmable 2-bit down counter. The global clock prescaler submodule (GCP) output signal is prescaled by the value defined in [Table 16-9](#) according to the UCPRE[0:1] bits in the EMIOS_CCR n . The output is clocked every time the counter reaches zero. Counting is enabled by setting the UCPREN bit in the EMIOS_CCR n . The counter can be stopped at any time by clearing this bit, thereby stopping the internal counter in the unified channel.

16.4.4.3 Effect of Freeze on a Unified Channel

When in debug mode and the EMIOS_MCR[FRZ] bit and the EMIOS_CCR n [FREN] bit are both set, the internal counter and the unified channel’s capture and compare functions are halted. The UC is frozen in its current state.

During freeze, all registers are accessible. When the unified channel is operating in an output mode, the force match functions remain available, allowing the software to force the output to the desired level.

For input modes, any input events that occurs while the channel is frozen are ignored.

When exiting debug mode or freeze enable bit is cleared (FRZ in the EMIOS_MCR or FREN in the EMIOS_CCR n) the channel actions resume.

16.4.4.4 Unified Channels Operating Modes

The mode of operation of a unified channel is determined by the mode select bits MODE[0:6] in the EMIOS_CCR n . See [Table 16-10](#) for details.

When entering an output mode (except for GPIO mode), the output flip-flop is set to the complement of the EDPOL bit in the EMIOS_CCR n .

Because the internal counter EMIOS_CCNTR n continues to run in all modes (except for GPIO mode), it is possible to use this counter as the UC time base unless it (the internal counter) is a required resource in the operation of the selected mode.

To provide smooth waveform generation while allowing A and B registers to be asynchronously updated during UC operation, the double-buffered modes MCB, OPWFMB, OPWMB, and OPWMCB are provided (beginning at [Section 16.4.4.15, “Modulus Counter Buffered Mode \(MCB\)”](#)). In these modes the A and B registers are double buffered. Descriptions of the double-buffered modes are presented separately, because there are several basic differences from the single-buffered MC, OPWFM, OPWM, and OPWMC modes.

In the following pages, [Section 16.4.4.4.1, “General Purpose Input/Output Mode \(GPIO\)”](#) through [Section 16.4.4.4.14, “Output Pulse-Width Modulation Mode \(OPWM\)”](#) and [Section 16.4.4.4.18, “Output Pulse-Width Modulation, Buffered Mode \(OPWMB\)”](#) explain in detail the unified channels’ modes of operation.

16.4.4.4.1 General Purpose Input/Output Mode (GPIO)

The following table lists the general purpose input/output mode settings:

Table 16-14. GPIO Operating Mode

MODE[0:6]	Unified Channel GPIO Operating Mode
0b0000000	General purpose input/output mode (input)
0b0000001	General purpose input/output mode (output)

In GPIO mode, all input capture and output compare functions of the UC are disabled, the internal counter (EMIOS_CCNTR n register) is cleared and disabled. All control bits remain accessible. To prepare the UC for a new operating mode, writing to registers EMIOS_CADR n or EMIOS_CBDR n stores the same value in registers A1/A2 or B1/B2, respectively.

MODE[6] bit selects between input (MODE[6] = 0) and output (MODE[6] = 1) modes.

It is required that when changing MODE[0:6], the application software goes to GPIO mode first to reset the UC's internal functions properly. Failure to do this can lead to invalid and unexpected output compares and input capture results, or can cause the FLAGs to be set incorrectly.

In GPIO input mode, the FLAG generation is determined according to EDPOL and EDSEL bits and the input pin status can be determined by reading the UCIN bit.

In GPIO output mode, the unified channel is used as a single output port pin and the value of the EDPOL bit is permanently transferred to the output flip-flop.

NOTE

The GPIO modes provided in the eMIOS are particularly useful as interim modes when certain other eMIOS modes are being dynamically configured and enabled or disabled during the execution of the application. For normal GPIO function on the eMIOS pins, it is recommended that the SIU be used to configure those pins as system GPIO. See [Section 6.2.1.3](#), “General-Purpose I/O (GPIO[0:213])” pins.

16.4.4.4.2 Single-action Input Capture Mode (SAIC)

The following table lists the single action input capture mode settings:

Table 16-15. SAIC Operating Mode

MODE[0:6]	Unified Channel SAIC Operating Mode
0b0000010	Single action input capture mode

In SAIC mode, when a triggering event occurs on the input pin, the value on the selected time base is captured into register A2. At the same time, the FLAG bit is set to indicate that an input capture has occurred. Register EMIOS_CADR n returns the value of register A2.

The input capture is triggered by a rising, falling or either edges in the input pin, as configured by EDPOL and EDSEL bits in EMIOS_CCR n .

Figure 16-16 shows how the unified channel can be used for input capture.

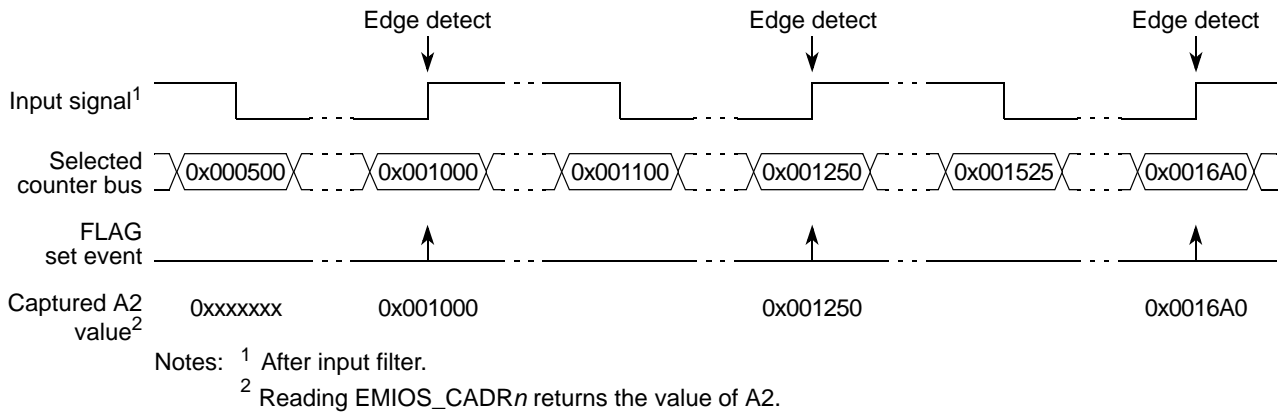

Figure 16-16. Single-action Input Capture Example

16.4.4.4.3 Single-action Output Compare Mode (SAOC)

The following table lists the single action output compare mode setting:

Table 16-16. SAOC Operating Mode

MODE[0:6]	Unified Channel SAOC Operating Mode
0b0000011	Single-action output compare mode

In SAOC mode, a match value is loaded in register A2 and then transferred to register A1 to be compared with the selected time base. When a match occurs, the EDSEL bit selects if the output flip-flop is toggled or if the value in EDPOL is transferred to it. At the same time, the FLAG bit is set to indicate that the output compare match has occurred. Writing to register EMIOS_CADR n stores the value in register A2 and reading to register EMIOS_CADR n returns the value of register A1.

An output compare match can be simulated in software by setting the FORCMA bit in EMIOS_CCR n . In this case, the FLAG bit is not set.

Figure 16-17 shows how to use the unified channel perform a single output compare while transferring EDPOL to the output flip-flop. This figure toggles the output flip-flop with Figure 16-18 at each match.

Figure 16-17. SAOC Example with EDPOL Value Transferred to the Output Flip-flop

Figure 16-18 shows how to use the unified channel perform a single output compare while transferring EDPOL to the output flip-flop. This figure toggles the output flip-flop with Figure 16-17 at each match.

Figure 16-18. SAOC Example Toggling the Output Flip-flop

16.4.4.4 Input Pulse-Width Measurement Mode (IPWM)

The following table lists the input pulse-width measurement mode setting:

Table 16-17. IPWM Operating Mode

MODE[0:6]	Unified Channel IPWM Operating Mode
0b0000100	Input pulse-width measurement mode

The IPWM mode measures the width of a positive or negative pulse by capturing the leading edge on register B1 and the trailing edge on register A2. Successive captures are done on consecutive edges of opposite polarity. The leading edge sensitivity (pulse polarity) is selected by EDPOL bit in the

EMIOS_CCR*n*. Registers EMIOS_CADR*n* and EMIOS_CBDR*n* return the values in register A2 and B1, respectively.

The capture function of register A2 remains disabled until the first leading edge triggers the first input capture on register B2. When this leading edge is detected, the count value of the selected time base is latched into register B2; the FLAG bit is not set. When the trailing edge is detected, the count value of the selected time base is latched into register A2 and, at the same time, the FLAG bit is set and the content of register B2 is transferred to register B1.

If subsequent input capture events occur while the corresponding FLAG bit is set, registers A2, B1, and A1 are updated with the latest captured values and the FLAG remains set. Registers EMIOS_CADR*n* and EMIOS_CBDR*n* return the value in registers A2 and B1, respectively.

To guarantee coherent access, reading EMIOS_CADR*n* forces B1 to be updated with the content of register A1. At the same time transfers between B2 and B1 are disabled until the next read of the EMIOS_CBDR*n* register. Reading EMIOS_CBDR*n* forces B1 to be updated with A1 register content and re-enables transfers from B2 to B1, to take effect at the next trailing edge capture. Transfers from B2 to A1 are not blocked at any time.

The input pulse width is calculated by subtracting the value in B1 from A2.

Figure 16-19 shows how the unified channel can be used for input pulse-width measurement.

- Notes: ¹ After input filter.
² Reading EMIOS_CADR*n* returns the value of A2, writing EMIOS_CADR*n* writes to A2.
³ Reading EMIOS_CBDR*n* returns the value of B1, writing EMIOS_CBDR*n* writes to B1.

Figure 16-19. Input pulse-width Measurement Example

Figure 16-20 shows the A1 and B1 updates when EMIOS_CADR_n and EMIOS_CBDR_n register reads occur. The A1 register always has coherent data related to the A2 register. Note also that when an EMIOS_CADR_n read is performed, the B1 register is loaded with A1 register content. This guarantee that the data in register B1 always has the coherent data related to the last EMIOS_CADR_n read. The B1 register updates remains locked until an EMIOS_CBDR_n read occurs. If an EMIOS_CADR_n read is performed, the B1 register is updated with A1 register content even if the B1 update is locked by a previous EMIOS_CADR_n read operation.

Figure 16-20. B1 and A1 Updates at EMIOS_CADR_n and EMIOS_CBDR_n Reads

Reading EMIOS_CADR_n followed by EMIOS_CBDR_n always provides coherent data. If coherent data is not required, invert the sequence of reads; read EMIOS_CBDR_n before reading EMIOS_CADR_n. If B1 register updates are blocked after an EMIOS_CADR_n read, a second EMIOS_CBDR_n read is required to release B1 register updates.

16.4.4.4.5 Input Period Measurement Mode (IPM)

The following table lists the input period measurement mode setting:

Table 16-18. IPM Operating Mode

MODE[0:6]	Unified Channel IPM Operating Mode
0b0000101	Input period measurement mode

The IPM mode allows the measurement of the period of an input signal by capturing two consecutive rising edges or two consecutive falling edges. Successive input captures are done on consecutive edges of the same polarity. The edge polarity is defined by the EDPOL bit in the EMIOS_CCR_n.

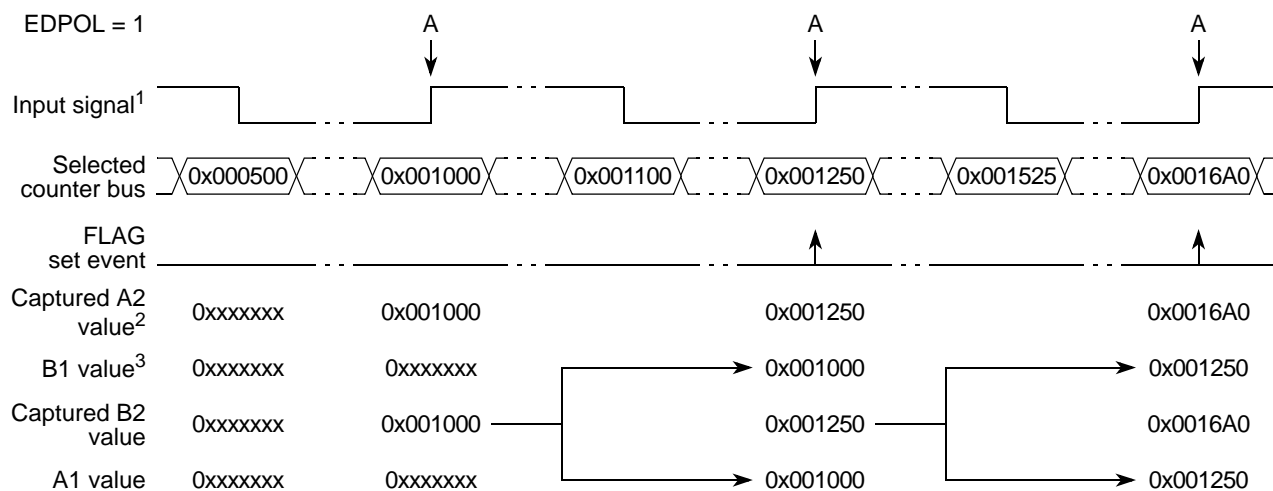

When the first edge of selected polarity is detected, the selected time base is latched into the registers A2 and B2, and the data previously held in register B2 is transferred to register B1. On this first capture the FLAG line is not set, and the values in registers B1 is meaningless. On the second and subsequent captures, the FLAG line is set and data in register B2 is transferred to register B1.

When the second edge of the same polarity is detected, the counter bus value is latched into registers A2 and B2, the data previously held in register B2 is transferred to data register B1 and to register A1. The FLAG bit is set to indicate that the start and end points of a complete period have been captured. This sequence of events is repeated for each subsequent capture. Registers EMIOS_CADR n and EMIOS_CBDR n return the values in register A2 and B1, respectively.

To allow coherent data, reading EMIOS_CADR n forces A1 content to be transferred to the B1 register and disables transfers between B2 and B1. These transfers are disabled until the next read of the EMIOS_CBDR n register. Reading EMIOS_CBDR n forces A1 content to be transferred to B1 and re-enables transfers from B2 to B1, to take effect at the next edge capture.

The input pulse period is calculated by subtracting the value in B1 from A2.

Figure 16-21 shows how the unified channel can be used for input period measurement.

- Notes: ¹ After input filter.
² Reading EMIOS_CADR n returns the value of A2.
³ Reading EMIOS_CBDR n returns the value of B1.

Figure 16-21. Input Period Measurement Example

Figure 16-22 describes the A1 and B1 register updates when EMIOS_CADR_n and EMIOS_CBDR_n read operations are performed. When an EMIOS_CADR_n read occurs the content of A1 is transferred to B1 thus providing coherent data in the A2 and B1 registers. Transfers from B2 to B1 are then blocked until EMIOS_CBDR_n is read. After EMIOS_CBDR_n is read, register A1 content is transferred to register B1 and the transfers from B2 to B1 are re-enabled to occur at the transfer edges, which is the leading edge in the Figure 16-22 example.

Figure 16-22. A1 and B1 Updates at EMIOS_CADR and EMIOS_CBDR Reads

16.4.4.4.6 Double-action Output Compare Mode (DAOC)

The following table lists the double-action output compare mode settings:

Table 16-19. DAOC Operating Modes

MODE[0:6]	Unified Channel DAOC Operating Mode
0b0000110	Double-action output compare (with FLAG set on the second match)
0b0000111	Double-action output compare (with FLAG set on both matches)

In the DAOC mode the leading and trailing edges of the variable pulse-width output are generated by matches occurring on comparators A and B, respectively.

When the DAOC mode is first selected (coming from GPIO mode) both comparators are disabled. Comparators A and B are enabled by updating registers A1 and B1 respectively and remain enabled until a match occurs on that comparator, when it is disabled again. To update registers A1 and B1, a write to A2 and B2 must occur and the EMIOS_CCR_n[ODIS] bit must be cleared.

The output flip-flop is set to the value of EMIOS_CCR_n[EDPOL] when a match occurs on comparator A and to the complement of EDPOL when a match occurs on comparator B.

MODE[6] controls if the EMIOS_CSR n [FLAG] is set on both matches or just on the second match (see Table 16-10 for details).

If subsequent enabled output compares occur on registers A1 and B1, pulses continue to generate, regardless of the state of the FLAG bit.

At any time, the EMIOS_CCR n [FORCMA] and EMIOS_CCR n [FORCMB] bits allow the software to force the output flip-flop to the level corresponding to a comparison event in comparator A or B, respectively. The FLAG bit is not affected by these forced operations.

NOTE

If both registers (A1 and B1) are loaded with the same value, the unified channel behaves as if a single match on comparator B had occurred; that is, the output flip-flop is set to the complement of EDPOL bit and the FLAG bit is set.

Figure 16-23 and Figure 16-24 show how the unified channel can be used to generate a single output pulse with FLAG bit being set on the second match or on both matches, respectively.

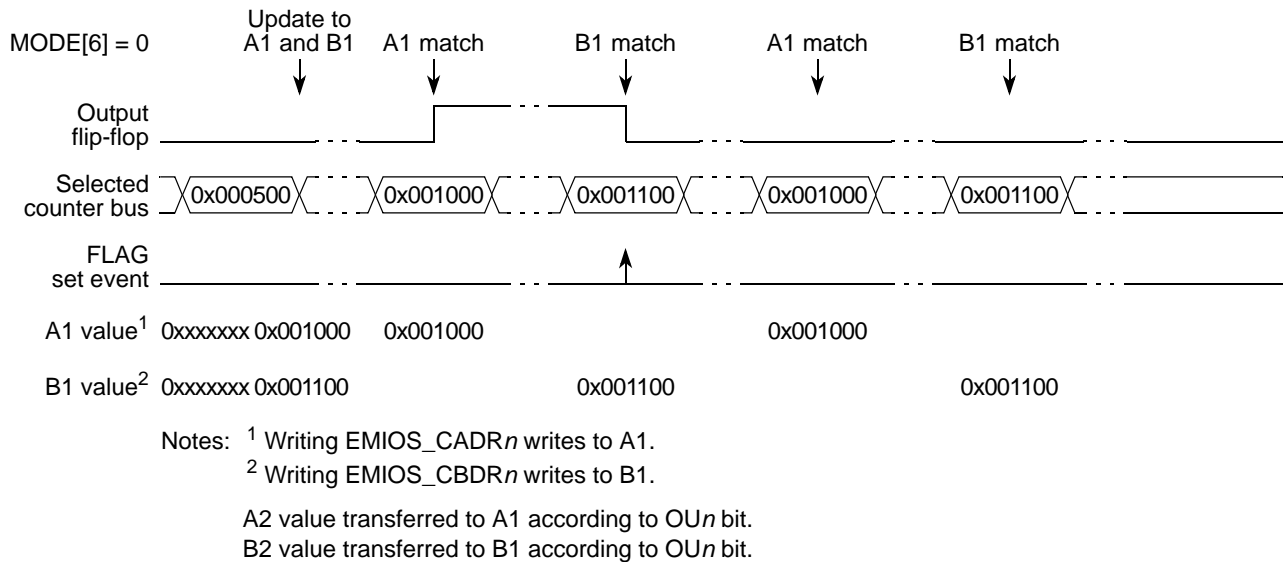

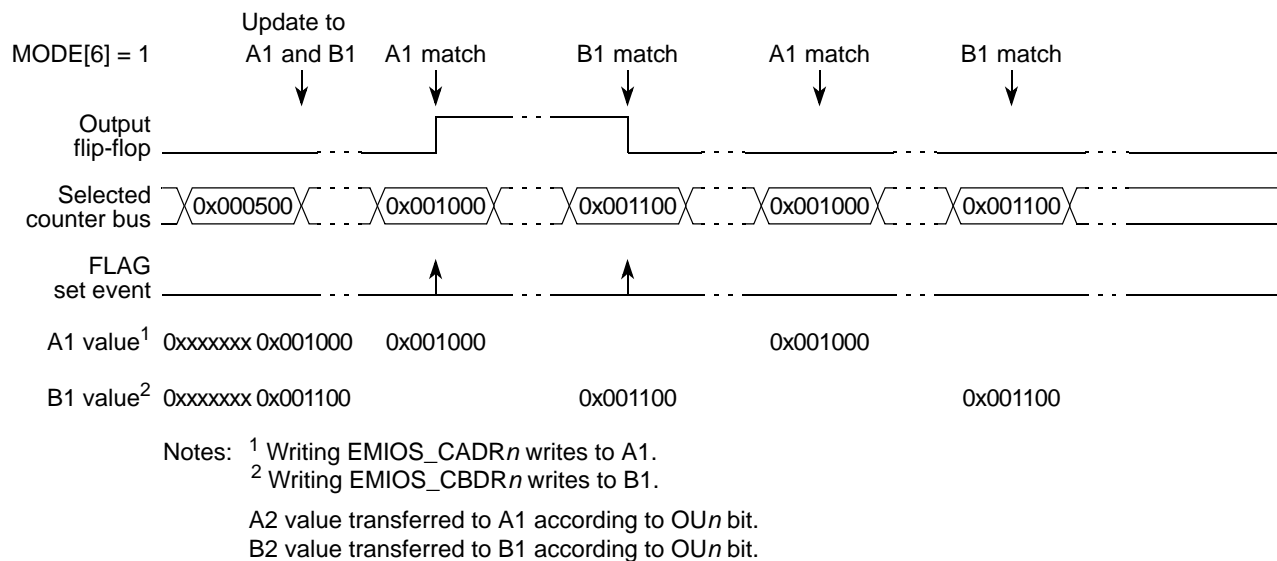

Figure 16-23. Double Action Output Compare with FLAG Set on the Second Match

Figure 16-24. Double-action Output Compare with FLAG Set on Both Matches

16.4.4.4.7 Pulse/Edge Accumulation Mode (PEA)

The following table lists the pulse/edge accumulation mode settings:

Table 16-20. PEA Operating Mode

MODE[0:6]	Unified Channel PEA Operating Mode
0b0001000	Pulse/edge accumulation (continuous)
0b0001001	Pulse/edge accumulation (single shot)

The PEA mode returns the time taken to detect a desired number of input events. MODE[6] bit selects between continuous or single shot operation.

After writing to register A1, the internal counter is cleared on the first input event, ready to start counting input events and the selected timebase is latched into register B2. On the match between the internal counter and register A1, a counter bus capture is triggered to register A2 and B2. The data previously held in register B2 is transferred to register B1 and the FLAG bit is set to indicate that an event has occurred. The desired time interval can be determined by subtracting register B1 from A2. Registers EMIOS_CADR_n and EMIOS_CBDR_n return the values in register A2 and B1, respectively.

To guarantee coherent access, reading EMIOS_CADR_n disables transfers between B2 and B1. These transfers are disabled until the next read of the EMIOS_CBDR_n register. Reading the EMIOS_CBDR_n register re-enables transfers from B2 to B1, to take effect at the next transfer event, as described above.¹

Triggering of the counter clock (an input event) is done by a rising or falling edge or both edges on the input pin. The polarity of the triggering edge is selected by the EDSEL and EDPOL bits in EMIOS_CCR_n.

1. If B1 was not updated due to B2 to B1 transfer being disabled after reading register EMIOS_CADR_n, further EMIOS_CADR_n and EMIOS_CBDR_n reads do not return coherent data until a new bus capture is triggered to registers A2 and B2. The capture event is indicated when the channel FLAG asserts. If enabled, the FLAG also generates an interrupt.

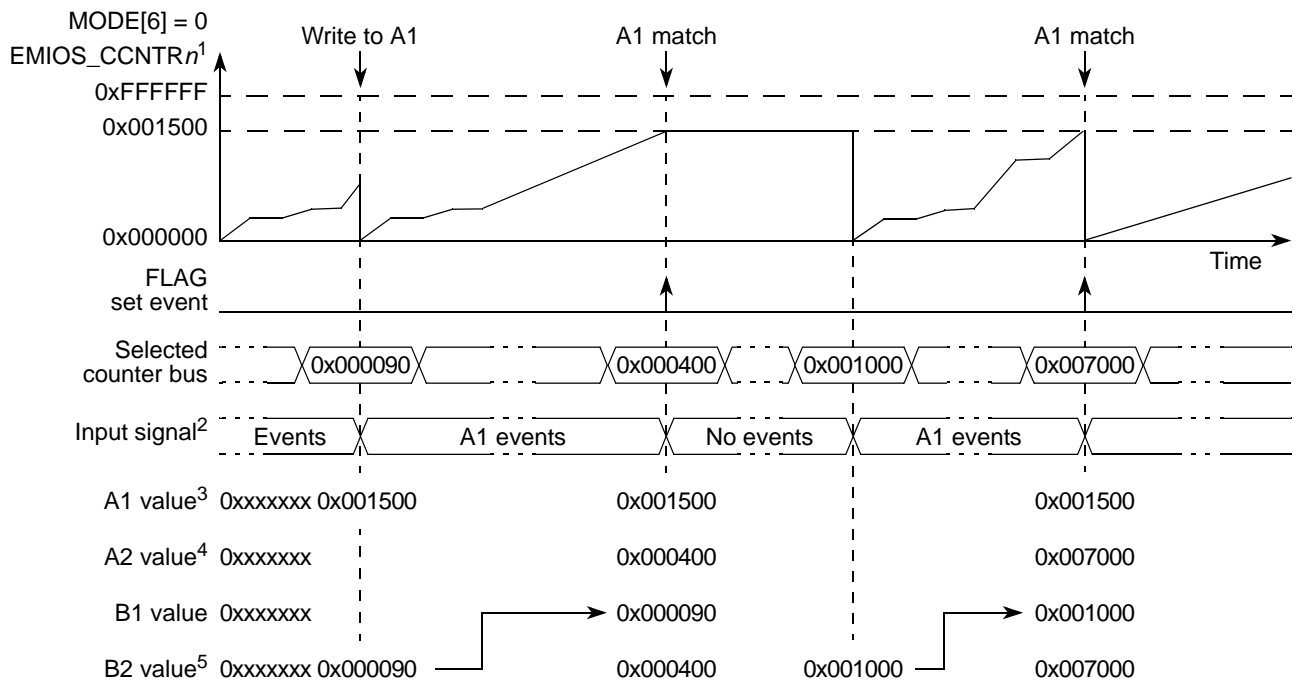

For continuous operating mode (MODE[6] cleared), the counter is cleared on the next input event after a FLAG generation and continues to operate as described above.

For single shot operation (MODE[6] set), the counter is not cleared or incremented after a FLAG generation, until a new writing operation to register A is performed.

NOTE

The FORCMA and FORCMB bits have no effect when the unified channel is configured for PEA mode.

Figure 16-25 and Figure 16-26 show how the unified channel can be used for continuous and single shot pulse/edge accumulation mode.

- Notes:
- ¹ Cleared on the first input event after writing to register A1.
 - ² After input filter.
 - ³ Writing EMIOS_CADRn writes to A1.
 - ⁴ Reading EMIOS_CADRn returns the value of A2.
 - ⁵ Reading EMIOS_CBDRn returns the value of B1.

Figure 16-25. Pulse/Edge Accumulation Continuous Mode Example

Figure 16-26. Pulse/Edge Accumulation Single-shot Mode Example

16.4.4.4.8 Pulse and Edge Counting Mode (PEC)

The following table lists the pulse and edge counting mode settings:

Table 16-21. PEC Operating Mode

MODE[0:6]	Unified Channel PEC Operating Mode
0b0001010	Pulse and edge counting (continuous)
0b0001011	Pulse and edge counting (single shot)

The PEC mode returns the amount of pulses or edges detected on the input for a desired time window. MODE[6] bit selects between continuous or single shot operation.

Triggering of the internal counter is done by a rising- or falling-edge or both edges on the input signal. The polarity and the triggering edge is selected by EDSEL and EDPOL bits in EMIOS_CCR_n.

Register A1 holds the start time and register B1 holds the stop time for the time window. After writing to register A1, when a match occur between comparator A and the selected timebase, the internal counter is cleared and it is ready to start counting input events. When the time base matches comparator B1, the

internal counter is disabled and its content is transferred to register A2. At the same time the FLAG bit is set. Reading registers EMIOS_ALTAn or A2 returns the amount of detected pulses.

For continuous operation (MODE[6] cleared), the next match between comparator A and the selected time base clears the internal counter and counting is enabled again. To guarantee the accuracy when reading EMIOS_CCNTRn after the flag is set, the software must check if the time base value is out of the time interval defined by registers A1 and B1. Alternatively register A2 always holds the latest available measurement providing coherent data at any time after the first FLAG occurs. This register is addressed by the alternate address EMIOS_ALTAn.

For single shot operation (MODE[6] set), the next match between comparator A and the selected time base has no effect, until a new write to register A is performed. The EMIOS_CCNTRn content is also transferred to register A2 when a match in the B comparator occurs.

NOTE

The FORCMA and FORCMB bits have no effect when the unified channel is configured for PEC mode.

Figure 16-27 and Figure 16-28 show how the unified channel can be used for continuous or single shot pulse/edge counting mode.

Figure 16-27. Pulse/Edge Counting Continuous Mode Example

Figure 16-28. Pulse/Edge Counting Single-Shot Mode Example

16.4.4.4.9 Quadrature Decode Mode (QDEC)

The following table lists the quadrature decode mode settings:

Table 16-22. QDEC Operating Mode

MODE[0:6]	Unified Channel QDEC Operating Mode
0b0001100	Quadrature decode (for count and direction encoders type)
0b0001101	Quadrature decode (for phase_A and phase_B encoders type)

Quadrature decode mode uses UC n operating in QDEC mode and the programmable input filter (PIF) from UC[n-1]. UC[n-1] can be configured, at the same time, to an operation mode that does not use I/O pins, such as MC mode (modulus counter). The connection among the UCs is circular; that is, when UC0 is running in QDEC mode, the programmable input filter from UC23 is being used.

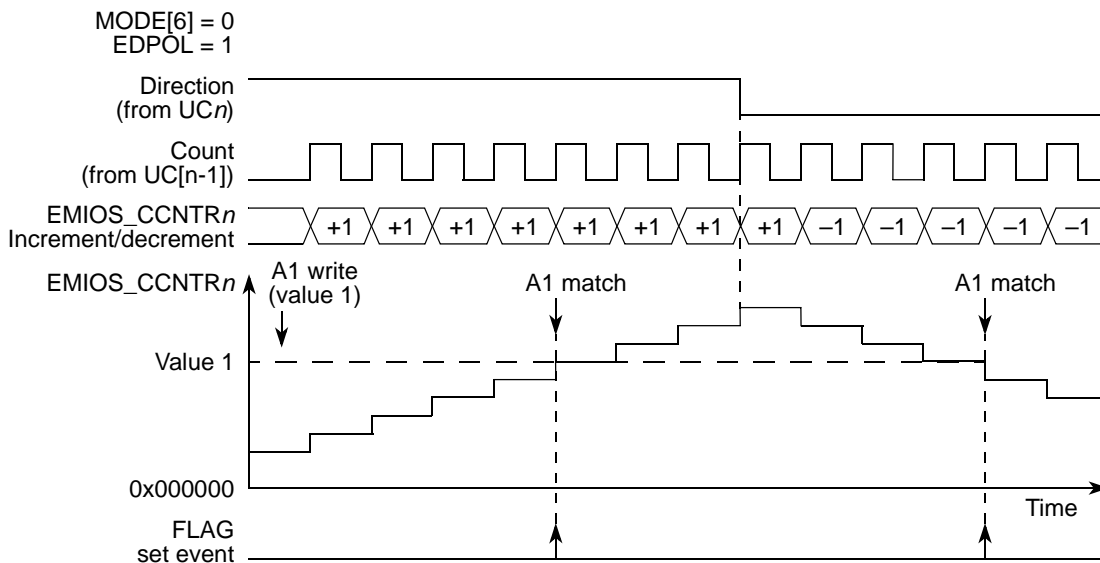

This mode generates a FLAG every time the internal counter matches A1 register. The internal counter is automatically selected and is not cleared when entering this mode.

MODE[6] bit selects which type of encoder is used: count and direction encoder or phase_A and phase_B encoders.

When operating with count and direction encoder (MODE[6] cleared), UC n input pin must be connected to the direction signal and UC[n-1] input pin must be connected to the count signal of the quadrature encoder. UC n EDPOL bit selects count direction according to direction signal and UC[n-1] EDPOL bit selects if the internal counter is clocked by the rising or falling edge of the count signal.

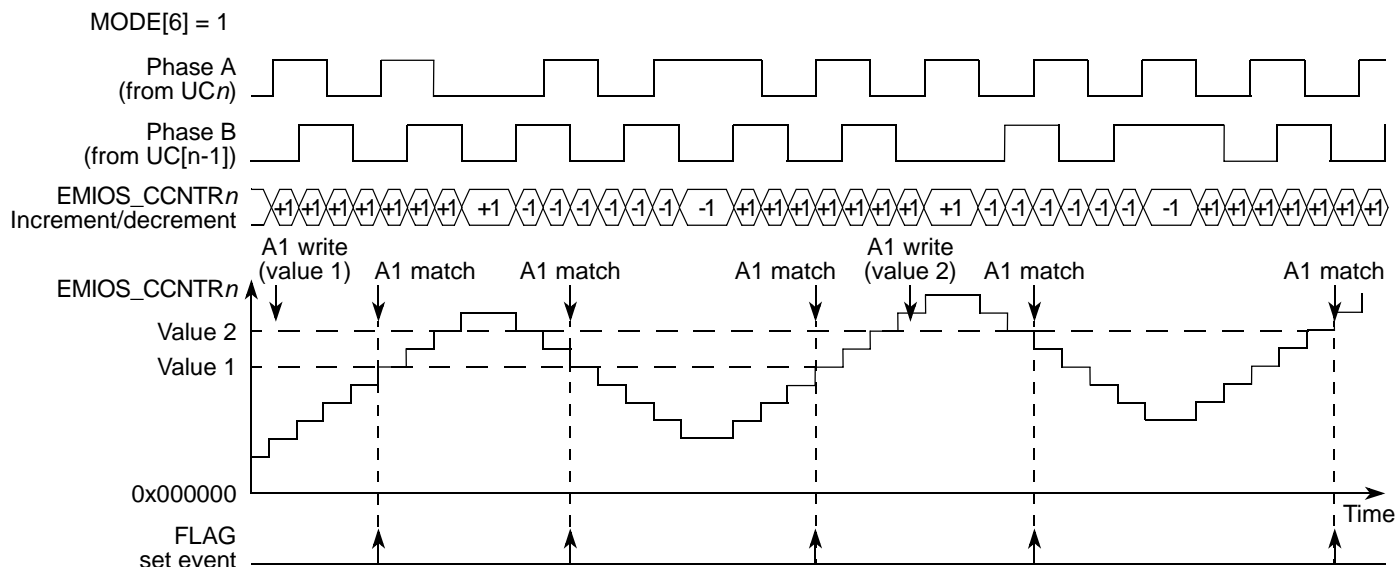

When operating with phase_A and phase_B encoder (MODE[6] set), UC_n input pin must be connected to the phase_A signal and UC[n-1] input pin must be connected to the phase_B signal of the quadrature encoder. EDPOL bit selects the count direction according to the phase difference between phase_A and phase_B signals.

Figure 16-29 and Figure 16-30 show two unified channels configured to quadrature decode mode for count and direction encoder and phase_A and phase_B encoders, respectively.

Note: Writing EMIOS_CADR_n writes to A1.

Figure 16-29. Quadrature Decode Mode Example with Count and Direction Encoder

Note: Writing EMIOS_CADR_n writes to A1.

Figure 16-30. Quadrature Decode Mode Example with Phase_A and Phase_B Encoder

16.4.4.4.10 Windowed Programmable Time Accumulation Mode (WPTA)

The WPTA mode accumulates the sum of the total high time or low time of an input signal over a programmable interval (time window).

The prescaler bits UCPRE[0:1] in EMIOS_CCR n define the increment rate of the internal counter.

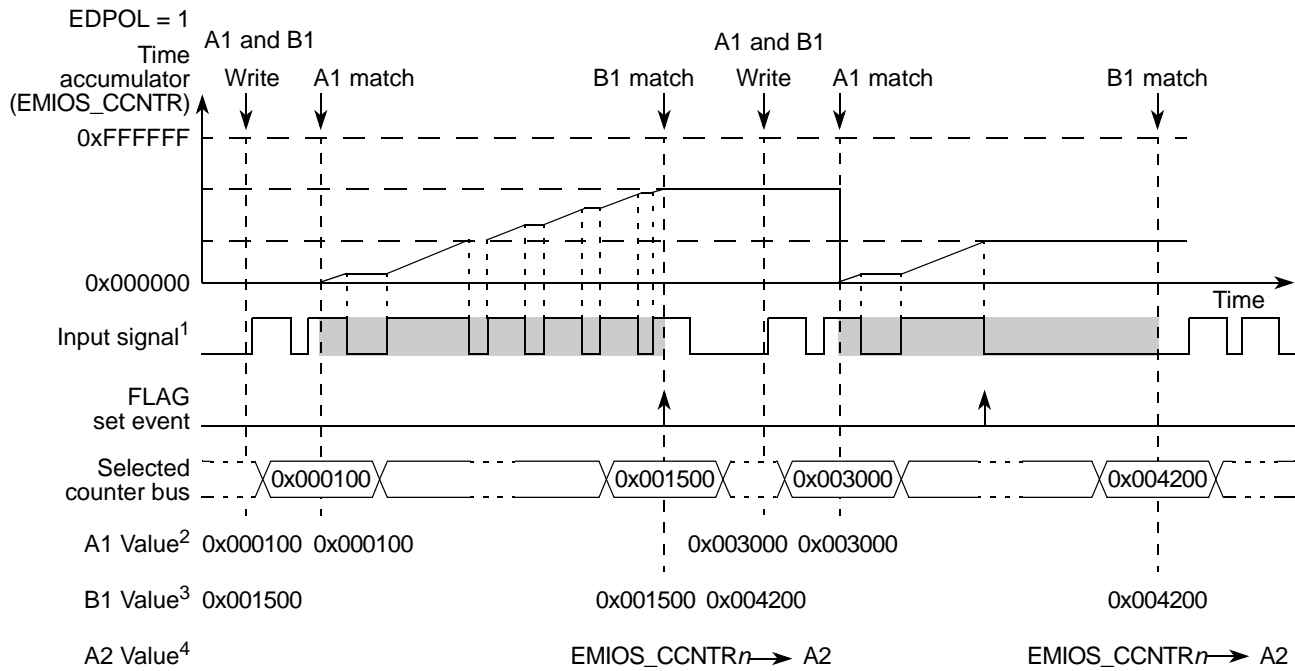

Register A1 holds the start time and register B1 holds the stop time of the programmable time interval. When a match occurs between register A and the selected timebase, the internal counter is cleared and it is ready to start counting. The internal counter is used as a time accumulator; that is, it counts up when the input signal has the same polarity of EDPOL bit in EMIOS_CCR n and does not count otherwise. When a match occurs in comparator B, the internal counter is disabled regardless of the input signal polarity and the FLAG bit is set. At the same time the content of EMIOS_CCNTR n is transferred to register A2. Reading EMIOS_CCNTR n or A2 returns the high or low time of the input signal.

EMIOS_CCNTR n is stable only outside the time window defined from A1 to B1 matches, otherwise its contents reflects a count in progress and not the final value. Alternatively to EMIOS_CCNTR n , register A2 returns the latest available measurement. Because this register is updated only at comparator B matches, it always contains stable and up-to-date data. In WPTA mode this register is accessible through the alternate register address EMIOS_ALTAn.

NOTE

The FORCMA and FORCMB bits have no effect when the unified channel is configured for WPTA mode.

Figure 16-31 shows how the unified channel can be used to accumulate high time.

- Notes:
- ¹ After input filter.
 - ² Writing EMIOS_CADR_n writes to A1.
 - ³ Writing EMIOS_CBDR_n writes to B1.
 - ⁴ Reading EMIOS_ALTAN returns the value of A2. (EMIOS_ALTA only used in PEC and WPTA modes)

Figure 16-31. Windowed Programmable Time Accumulation Example

16.4.4.4.11 Modulus Counter Mode (MC)

The following table lists the modulus counter settings:

Table 16-23. MC Operating Modes

MODE[0:6]	Unified Channel MC Operating Mode
0b0010000	Modulus counter. Up counter, internal clock source.
0b0010001	Modulus counter. Up counter, external clock source.
0b0010010–0b0010011	Reserved
0b0010100	Modulus counter. Up/down counter, no change in counter direction upon match of input counter and register B1, internal clock source.
0b0010101	Modulus counter. Up/down counter, no change in counter direction upon match of input counter and register B1, external clock source.

Table 16-23. MC Operating Modes (continued)

MODE[0:6]	Unified Channel MC Operating Mode
0b0010110	Modulus counter. Up/down counter, change in counter direction upon match of input counter and register B1 and sets the FLAG, internal clock source.
0b0010111	Modulus counter. Up/down counter, change in counter direction upon match of input counter and register B1 and sets the FLAG, external clock source.

The MC mode can provide a time base for a counter bus or a general purpose timer.

MODE[6] bit selects internal or external clock source when cleared or set, respectively. When external clock is selected, the input signal pin is used as the source and the triggering polarity edge is selected by the EDPOL and EDSEL in the EMIOS_CCR n .

When software selects the modulus counter mode, the internal counter is initially reset to 0. The internal counter counts up from the current value until it matches the value in register A1. Register B1 is cleared and is not accessible to the MCU. MODE[4] bit selects up mode or up/down mode, when cleared or set, respectively.

When in up count mode, a match between the internal counter and register A1 sets the FLAG and clears the internal counter.

When in up/down count mode, a match between the internal counter and register A1 sets the FLAG and changes the counter direction from increment to decrement. A match between register B1 and the internal counter changes the counter direction from decrement to increment and sets the FLAG only if MODE[5] bit is set.

NOTE

The FORCMA and FORCMB bits have no effect when the unified channel is configured for MC mode.

NOTE

Any update to the A register takes place immediately, regardless of the current state of the counter and whether the counter is in up mode, or up/down mode.

Figure 16-32 and Figure 16-33 shows how to use the unified channel as a modulus counter in up mode and up/down mode, respectively.

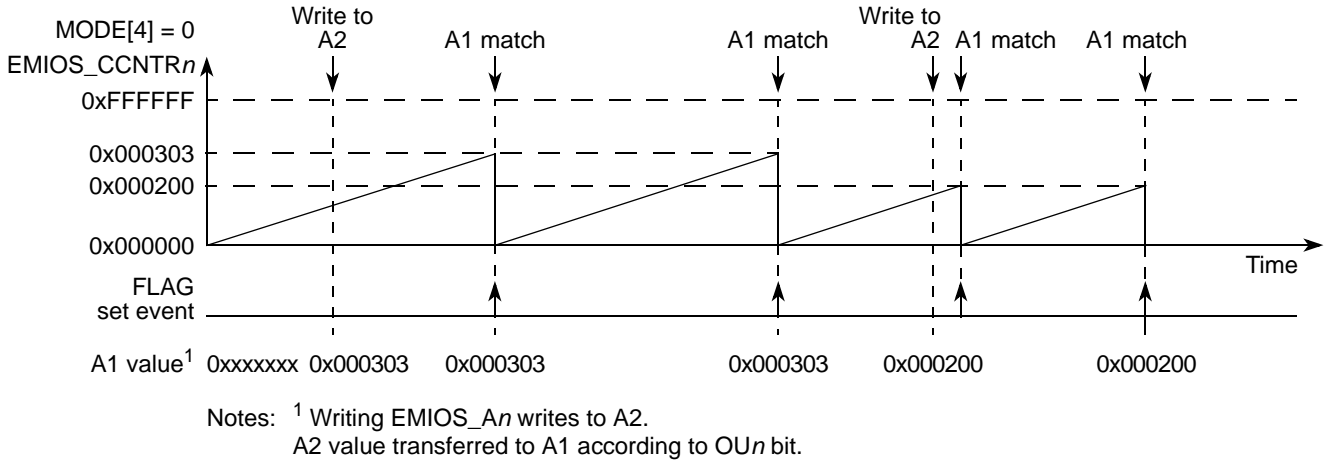

Figure 16-32. Modulus Counter Up Mode Example

Figure 16-33. Modulus Counter Up/Down Mode Example

16.4.4.4.12 Output Pulse-Width and Frequency Modulation Mode (OPWFM)

The following table lists the output pulse-width and frequency modulation mode settings:

Table 16-24. OPWFM Operating Mode

MODE[0:6]	Unified Channel OPWFM Operating Mode
0b0011000	Output pulse-width and frequency modulation. FLAG set at match of internal counter and comparator B, immediate update.
0b0011001	Output pulse-width and frequency modulation. FLAG set at match of internal counter and comparator B, next period update.
0b0011010	Output pulse-width and frequency modulation. FLAG set at match of internal counter and comparator A or comparator B, immediate update.
0b0011011	Output pulse-width and frequency modulation. FLAG set at match of internal counter and comparator A or comparator B, next period update.

In this mode, the duty cycle is (register A1 + 1) and the period is (register B1 + 1). The MODE[6] bit controls the transfer from register B2 to B1, which can be done either immediately (MODE[6] cleared), providing the fastest change in the duty cycle, or at every match of register A1 (MODE[6] set).

The internal counter is automatically selected as a time base, therefore the BSL[0:1] bits in register EMIOS_CCR n have no meaning. The output flip-flop's active state is the complement of EDPOL bit. The output flip-flop is active during the duty cycle (from the start of the cycle until a match occurs in comparator A). After the match in comparator A the output flip-flop is in the inactive state (the value of EDPOL) until the next cycle starts. When a match on comparator A occurs, the output flip-flop is set to the value of the EDPOL bit. When a match occurs on comparator B, the output flip-flop is set to the complement of the EDPOL bit and the internal counter is cleared.

FLAG can be generated at match B, when MODE[5] is cleared, or in both matches, when MODE[5] is set.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A or B respectively. Also, FORCMB clears the internal counter. The FLAG bit is not set by the FORCMA or FORCMB operations.

If subsequent comparisons occur on comparators A and B, the PWFm pulses continue to be output, regardless of the state of the FLAG bit.

To achieve 0% duty cycle, both registers A1 and B1 must be set to the same value. When a simultaneous match occurs on comparators A and B, the output flip-flop is set at every period to the value of EDPOL bit.

To temporarily change from the current duty cycle to 0% and then return to the current duty cycle, the sequence is the following:

1. If not currently stored, store value of register A.
2. Set A=B.
3. If immediate 0% duty cycle is desired, set FORCA=1.
4. To return to the previous duty cycle, restore register A with its former value.

100% duty cycle is possible by writing 0x000000 to register A. When a match occurs, the output flip-flop is set at every period to the complement of EDPOL bit. The transfer from register B2 to B1 is still controlled by MODE[6] bit.

To temporarily change from the current duty cycle to 100% and then return to the current duty cycle, the sequence is the following:

1. If not currently stored, store value of register A.
2. Set A=0.
3. If immediate 100% duty cycle is desired, set FORCB=1.
4. To return to the previous duty cycle, restore register A with its former value.

NOTE

Updates to the A register always occur immediately. If next period update is selected via the mode[6] bit, only the B register update is delayed until the next period.

Figure 16-34 shows the unified channel running in OPFWM mode with immediate register update.

Figure 16-34. OPFWM with Immediate Update

Figure 16-35 shows the unified channel running in OPFWM mode with next period update PFWM mode. In both figures EDPOL = 1, so the output is low during the duty cycle.

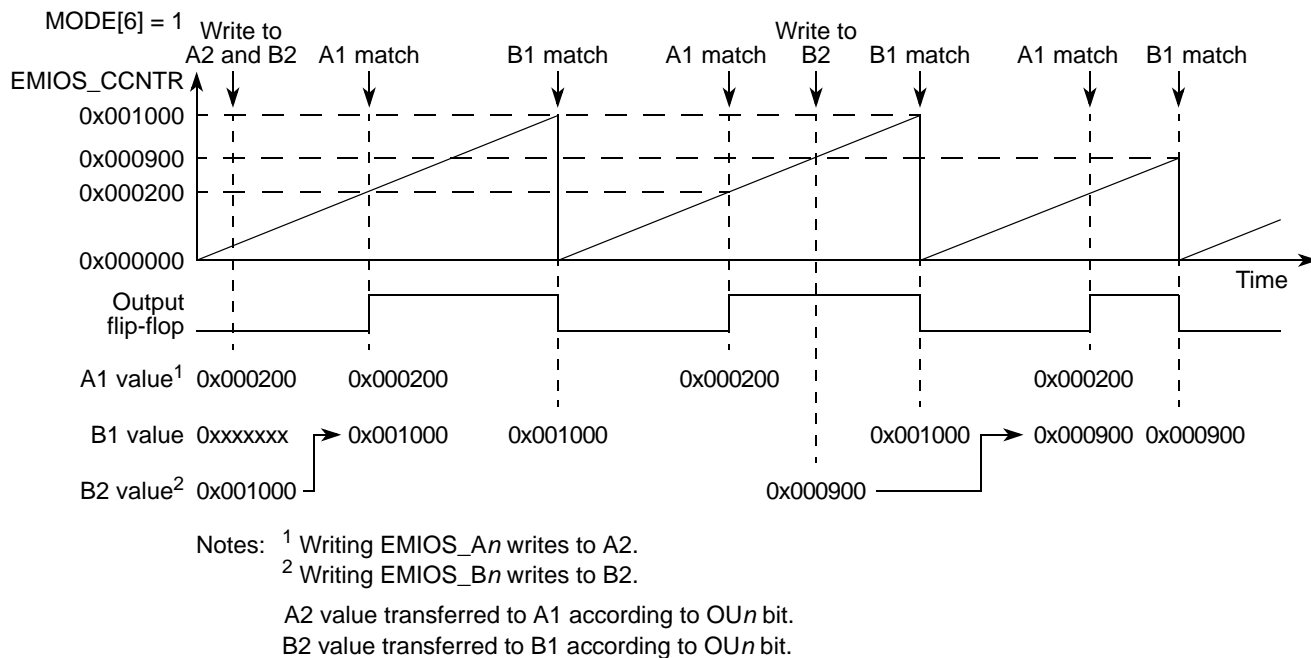

Figure 16-35. OPFWM with Next Period Update

Table 16-25 has additional illustrative examples.

Table 16-25. Examples of Output Waveforms

EDPOL	Duty Cycle	A (decimal)	B (decimal)	Waveform
0 Active high output	0%	1000	1000	H L
	25%	250	1000	H L
	50%	500	1000	H L
	75%	750	1000	H L
	100%	0	1000	H L
1 Active low output	0%	1000	1000	H L
	25%	250	1000	H L
	50%	500	1000	H L
	75%	750	1000	H L
	100%	0	1000	H L

16.4.4.4.13 Center-Aligned Output Pulse-Width Modulation with Dead-time Mode (OPWMC)

The following table lists the center-aligned output pulse-width modulation with dead-time mode settings:

Table 16-26. OPWMC Operating Mode

MODE[0:6]	Unified Channel OPWMC Operating Mode
0b0011100	Center-aligned output pulse-width modulation. FLAG set in trailing edge, trailing edge dead-time.
0b0011101	Center-aligned output pulse-width modulation. FLAG set in trailing edge, leading-edge dead-time.
0b0011110	Center-aligned output pulse-width modulation. FLAG set in both edges, trailing edge dead-time.
0b0011111	Center-aligned output pulse-width modulation. FLAG set in both edges, leading edge dead-time.

This operating mode generates a center-aligned PWM with dead-time insertion in the leading- or trailing-edge.

The selected counter bus must be running an up/down time base, as shown in [Figure 16-33](#). BSL[0:1] bits select the time base. Register A1 contains the ideal duty cycle for the PWM signal and is compared with the selected time base. Register B1 contains the dead time value and is compared with the internal counter. For a leading edge dead time insertion, the output PWM duty cycle is equal to the difference between register A1 and register B1, and for a trailing edge dead time insertion, the output PWM duty cycle is equal to the sum of register A1 and register B1. MODE[6] bit selects between trailing and leading dead time insertion, respectively.

NOTE

Synchronize the internal prescaler of the OPWMCB channel with the MCB channel prescaler and set them to the same value. This allows the A1 and B1 registers to represent the same time scale for duty cycle and dead time insertion.

When operating with leading edge dead time insertion, the first match between A1 and the selected time base clears the internal counter and switches the selected time base to the internal counter. When a match occurs between register B1 and the selected time base, the output flip-flop is set to the value of the EDPOL bit and the time base is switched to the selected counter bus. In the next match between register A1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously.

When operating with trailing edge dead time insertion, the first match between A1 and the selected time base sets the output flip-flop to the value of the EDPOL bit. In the next match between register A1 and the selected time base, the internal counter is cleared and the selected time base is switched to the internal counter. When a match occurs between register B1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit and the time base is switched to the selected counter bus. This sequence repeats continuously.

FLAG can be generated in the trailing edge of the output PWM signal when MODE[5] is cleared, or in both edges, when MODE[5] is set.

At any time, the FORCMA or FORCMB bits are equivalent to a successful comparison on comparator A or B with the exception that the FLAG bit is not set.

NOTE

When in freeze mode, the FORCMA or FORCMB bits only allow the software to force the output flip-flop to the level corresponding of a match on A or B respectively.

If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

To achieve a duty cycle of 100%, both registers A1 and B1 must be set to the same value. When a simultaneous match occurs between the selected time base and registers A1 and B1, the output flip-flop is set at every period to the value of EDPOL bit and the selected time base switches to the selected counter bus, allowing a new cycle to begin at any time, as previously described. 0% duty cycle is possible by writing 0x000000 to register A. When a match occurs, the output flip-flop is set at every period to the complement of EDPOL bit and the selected time base switches to the selected counter bus, allowing a new cycle to begin at any time, as previously described. In both cases, FLAG is generated regardless of MODE[5] bit.

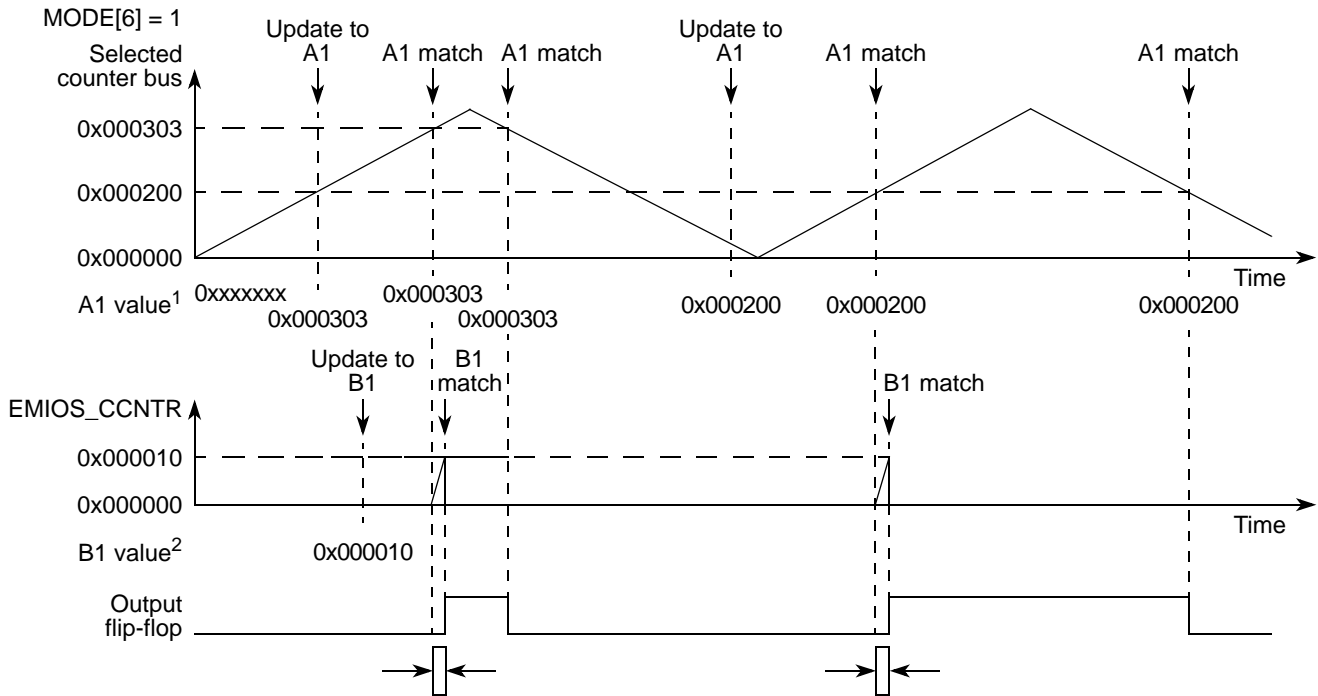

NOTE

If A1 and B1 are set to the 0x000000, a 0% duty cycle waveform is produced.

NOTE

Any updates to the A or B register takes place immediately.

Figure 16-36 and Figure 16-37 show the unified channel running in OPWMC with leading and trailing dead-time, respectively.

Notes: ¹ Writing EMIOS_An writes to A1.
² Writing EMIOS_Bn writes to B1.

A2 value transferred to A1 according to OUn bit.
 B2 value transferred to B1 according to OUn bit.

Figure 16-36. Output PWM with Leading Dead-time Insertion

Notes: ¹ Writing EMIOS_An writes to A2.
² Writing EMIOS_Bn writes to B1.

A2 value transferred to A1 according to OUn bit.
 B2 value transferred to B1 according to OUn bit.

Figure 16-37. Output PWMC with Trailing Dead-time Insertion

16.4.4.4.14 Output Pulse-Width Modulation Mode (OPWM)

The following table lists the output width modulation mode settings:

Table 16-27. OPWM Operating Modes

MODE[0:6]	Unified Channel OPWM Operating Mode
0b0100000	Output pulse-width modulation. FLAG set at match of internal counter and comparator B, immediate update.
0b0100001	Output pulse-width modulation. FLAG set at match of internal counter and comparator B, next period update.
0b0100010	Output pulse-width modulation. FLAG set at match of internal counter and comparator A or comparator B, immediate update.
0b0100011	Output pulse-width modulation. FLAG set at match of internal counter and comparator A or comparator B, next period update.

Registers A1 and B1 define the leading and trailing edges of the PWM output pulse, respectively. MODE[6] bit controls the transfer from register B2 to B1, which can be done either immediately (MODE[6] cleared), providing the fastest change in the duty cycle, or at every match of register A1 (MODE[6] set).

The value loaded in register A1 is compared with the value on the selected time base. When a match on comparator A occurs, the output flip-flop is set to the value of the EDPOL bit. When a match occurs on comparator B, the output flip-flop is set to the complement of the EDPOL bit.

FLAG can be generated at match B, when MODE[5] is cleared, or in both matches, when MODE[5] is set.

At any time, the FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on A or B respectively. The FLAG bit is not set by the FORCMA and FORCMB operations.

If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

To achieve 0% duty cycle, both registers A1 and B1 must be set to the same value. When a simultaneous match on comparators A and B occur, the output flip-flop is set at every period to the value of EDPOL bit. 0% duty cycle is possible by writing 0x000000 to register A. When a match occurs, the output flip-flop is set at every period to the complement of EDPOL bit. The transfer from register B2 to B1 is still controlled by MODE[6] bit.

NOTE

If A1 and B1 are set to the 0x000000, a 100% duty cycle waveform is produced.

NOTE

Updates to the A register always occur immediately. If next period update is selected via the mode[6] bit, only the B register update is delayed until the next period.

Figure 16-38 and Figure 16-39 show the unified channel running in OPWM with immediate update and next period update, respectively.

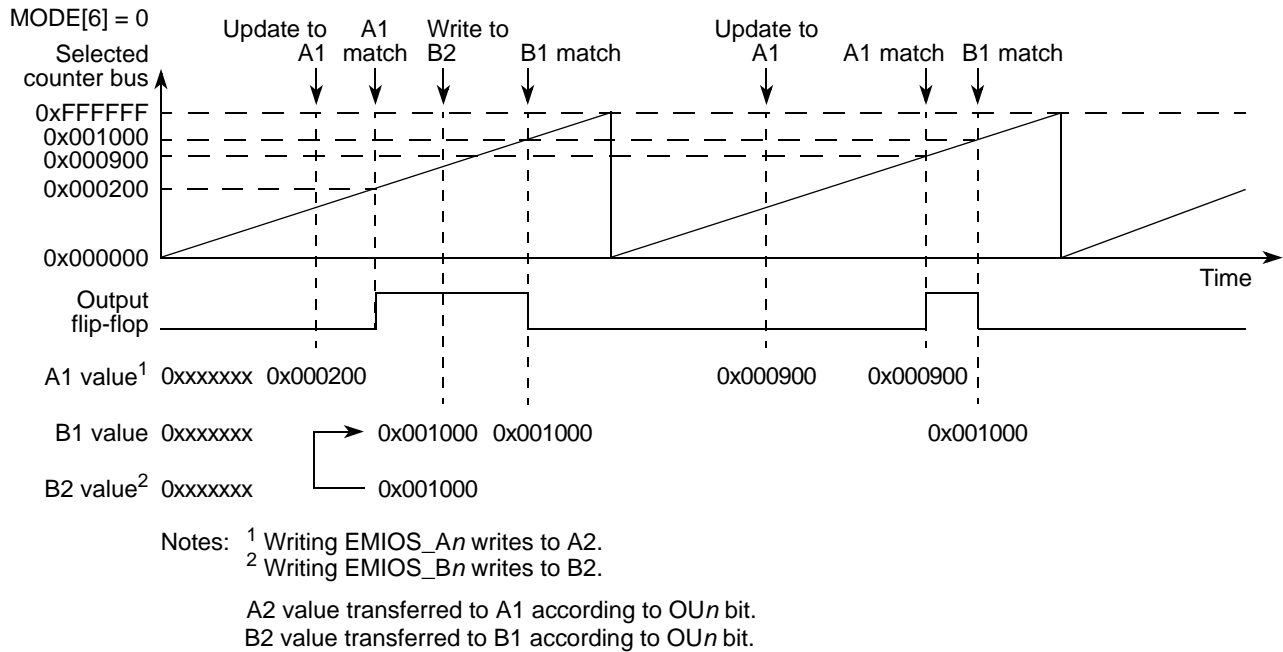

Figure 16-38. Output PWM with Immediate Update

Figure 16-39 show the unified channel running in OPWM with immediate update and next period update, respectively.

Figure 16-39. Output PWM with Next Period Update

16.4.4.4.15 Modulus Counter Buffered Mode (MCB)

The following table lists the modulus counter buffered mode settings:

Table 16-28. MCB Operating Modes

MODE[0:6]	Unified Channel MCB Operating Mode
0b1010000	Modulus up counter, buffered, internal clock
0b1010001	Modulus up counter, buffered, external clock
0b1010010–0b1010001	Reserved
0b1010100	Modulus up/down counter, buffered. FLAG set on one event, internal clock.
0b1010101	Modulus up/down counter, buffered. FLAG set on one event, external clock.
0b1010110	Modulus up/down counter, buffered. FLAG set on both events, internal clock.
0b1010111	Modulus up/down counter, buffered. FLAG set on both events, external clock.

The MCB mode provides a time base which can be shared with other channels through the internal counter buses. Register A1 is double buffered, thus allowing smooth transitions between cycles when changing the A2 register value asynchronously. The A1 register is updated at the cycle boundary, which is defined as when the internal counter reaches the value one. The internal counter values are within a range from one up to register A1 value in MCB mode.

The MODE[6] bit selects the internal clock source if clear or external if set. When an external clock is selected, the channel input pin is used as the channel clock source. The active edge of this clock is defined by EDPOL and EDSEL bits in the EMIOS_CCR channel register.

When entering the MCB mode, if up counter is selected (MODE[4] = 0), the internal counter starts counting up from its current value to until an A1 match occurs. On the next system clock cycle after an A1 match occurs, the internal counter is set to one and the counter continues counting up. If up/down mode is selected (MODE[4] = 1), the counter changes direction at the A1 match and counts down until it reaches one and is then set to count up again. In this mode B1 is set to one and cannot be changed, as it is used to generate a match to switch from down count to up count.

The MCB mode counts between one and the A1 register value. The counter cycle period in up count mode is equal to the A1 value. In up/down counter mode the period is defined by the formula: $(2 \times A1) - 2$.

Figure 16-40 illustrates the counter cycle for several A1 values. Register A1 is loaded with the A2 value at the cycle boundary. Thus any value written to A2 within cycle (n) is updated to A1 at the next cycle boundary, and therefore is used on cycle (n+1). The cycle boundary between cycle (n) and cycle (n+1) is defined as the first clock cycle of cycle (n+1). Flags are set when A1 matches occur.

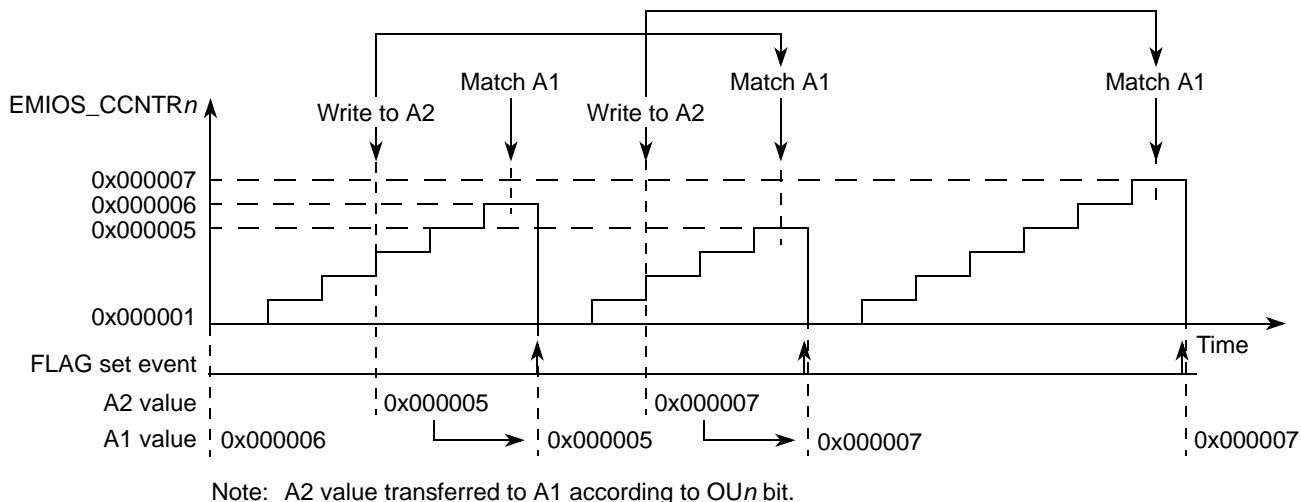

Figure 16-40. eMIOS MCB Mode Example — Up Operation

Figure 16-41 illustrates the MCB up/down counter mode. The A1 register is updated at the cycle boundary. If A2 is written in cycle (n), this new value is used in cycle (n+1) for the next A1 match.

Flags are generated only at an A1 match if MODE[5] is 0. If MODE[5] is 1, flags are also generated at the cycle boundary.

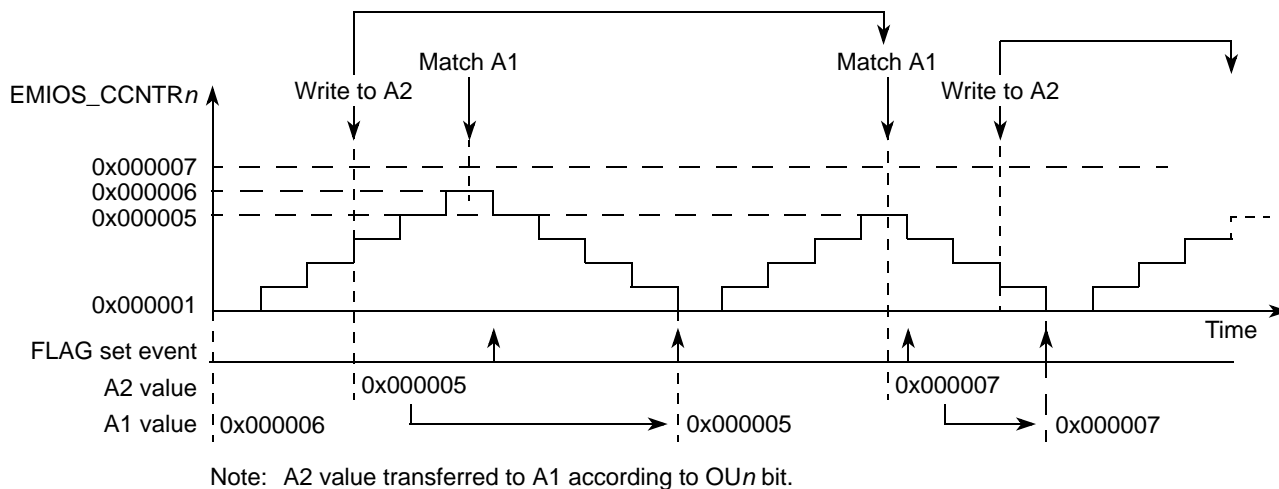

Figure 16-41. eMIOS MCB Mode Example — Up/Down Operation

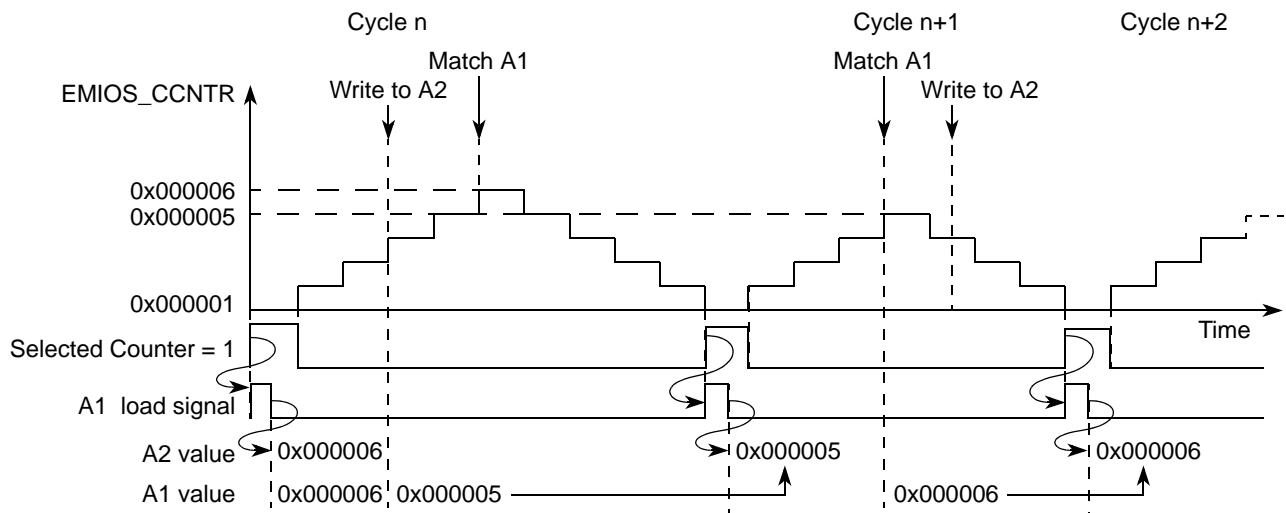

Figure 16-42 provides a more detailed illustration of the A1 update process in up counter mode. The A1 load signal is generated based on the detection of the internal counter reaching one, and has the duration of one system clock cycle. During the load pulse A1 still holds its previous value. It is actually updated at the second system clock cycle.

Note: A2 value transferred to A1 according to OUn bit.

Figure 16-42. eMIOS MCB Mode Example — Up Operation A1 Register Update

Figure 16-43 illustrates the A1 register update process in up/down counter mode. A2 can be written at any time within cycle (n) to be used in cycle (n+1). Thus, A1 receives the new value at the next cycle boundary. The EMIOS_OUDR[n] bits can be used to disable the update of A1 register.

Note: A2 value transferred to A1 according to OUn bit (the transfer is triggered by the A1 load signal).

Figure 16-43. eMIOS MCB Mode Example — Up/Down Operation A1 Register Update

16.4.4.4.16 Output Pulse-Width and Frequency Modulation Buffered Mode (OPWFMB)

The following table lists the output pulse-width and frequency modulation buffered mode settings:

Table 16-29. OPWFMB Operating Modes

MODE[0:6]	Unified Channel OPWFM Operating Mode
0b1011000	Output pulse-width and frequency modulation, buffered. FLAG set at match of internal counter and comparator B.
0b1011001	Reserved
0b1011010	Output pulse-width and frequency modulation, buffered. FLAG set at match of internal counter and comparator A or comparator B.

This mode generates waveforms with variable duty cycle and frequency. The internal channel counter is automatically selected as the time base, A1 sets the duty cycle and B1 determines the frequency. Both A1 and B1 are double buffered to allow smooth signal generation when changing the register values asynchronously. Both 0% and 100% duty cycles are supported.

To provide smooth and consistent channel operation, this mode differs substantially from the OPWFM mode. The main differences are in how A1 and B1 are updated, the delay from the A1 match to the output flip-flop transition, and the range of the internal counter which ranges from 1 up to B1 value.

When a match on comparator A occurs, the output register is set to the value of EDPOL. When a match on comparator B occurs, the output register is set to the complement of EDPOL. A B1 match also causes the internal counter to transition to 1, thus re-starting the counter cycle.

Figure 16-44 shows an example of OPWFMB mode operation. The output flip-flop transition occurs when the A1 or B1 match signal is negated, as detected by the negative edge of the A1 and B1 match signals. For example, if register A1 is set to 0x000004, the output flip-flop transitions 4 counter periods after the cycle starts, plus one system clock cycle. In the example shown in Figure 16-44 the prescaler ratio is set to two (refer to Section 16.5.3, “Time Base Generation”).

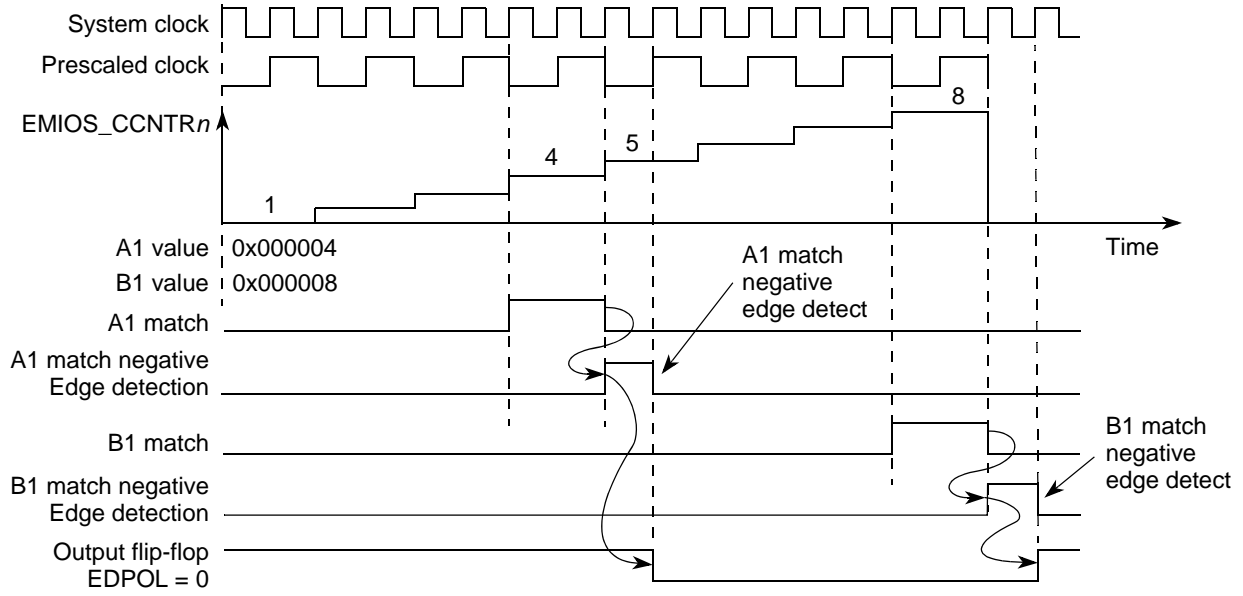

Figure 16-44. eMIOS OPWFMB Mode Example — A1/B1 Match to Output Register Delay

Figure 16-45 shows the generated output signal if A1 is 0. Since the counter does not reach zero in this mode, the channel internal logic infers a match as if A1 = 1, with the difference that in this case the positive edge of the match signal is used to trigger the output flip-flop transition instead of the positive edge that is used when A1 = 1. The A1 positive edge match signal from cycle (n+1) occurs at the same time as the B1 match negative edge from cycle (n). This allows the use of the A1 match positive edge to mask the B1 match negative edge when they occur at the same time. The result is that no transition occurs on the output flip-flop, and a 0% duty cycle is generated.

Figure 16-45. eMIOS OPWFMB Mode Example — A1 = 0 (0% Duty Cycle)

Figure 16-46 shows the timing for the A1 and B1 loading. A1 and B1 use the same signal to trigger a load, which is generated based on the selected counter reaching one. This event is defined as the cycle boundary. The load signal pulse has the duration of one system clock cycle and occurs at the first system clock period of every cycle of the counter. If A2 and B2 are written within cycle (n), their values are loaded into A1 and B1, respectively, at the first clock of cycle ($n+1$). The update disable bits, EMIOS_OUDR, can be used to control the update of these registers, thus allowing the delay of A1 and B1 update for synchronization purposes.

During the load pulse A1 still holds its old value, which is updated on the following system clock cycle. During the A1 load pulse, an internal by-pass allows the use of A2 instead of A1 for matches if A2 is either 0 or 1, thus allowing matches to be generated even when A1 is being loaded. This approach allows a uniform channel operation for any A2 value, including 1 and 0.

In Figure 16-46 it is assumed that the channel and global prescalers are set to one, meaning that the channel internal counter transition at every system clock cycle. FLAGS can be generated only on B1 matches when MODE[5] is cleared, or on both A1 and B1 matches when MODE[5] is set. Since B1 FLAG occurs at the cycle boundary, this flag can be used to indicate that A2 or B2 data written on cycle (n) were loaded to A1 or B1, respectively, thus generating matches in cycle ($n+1$).

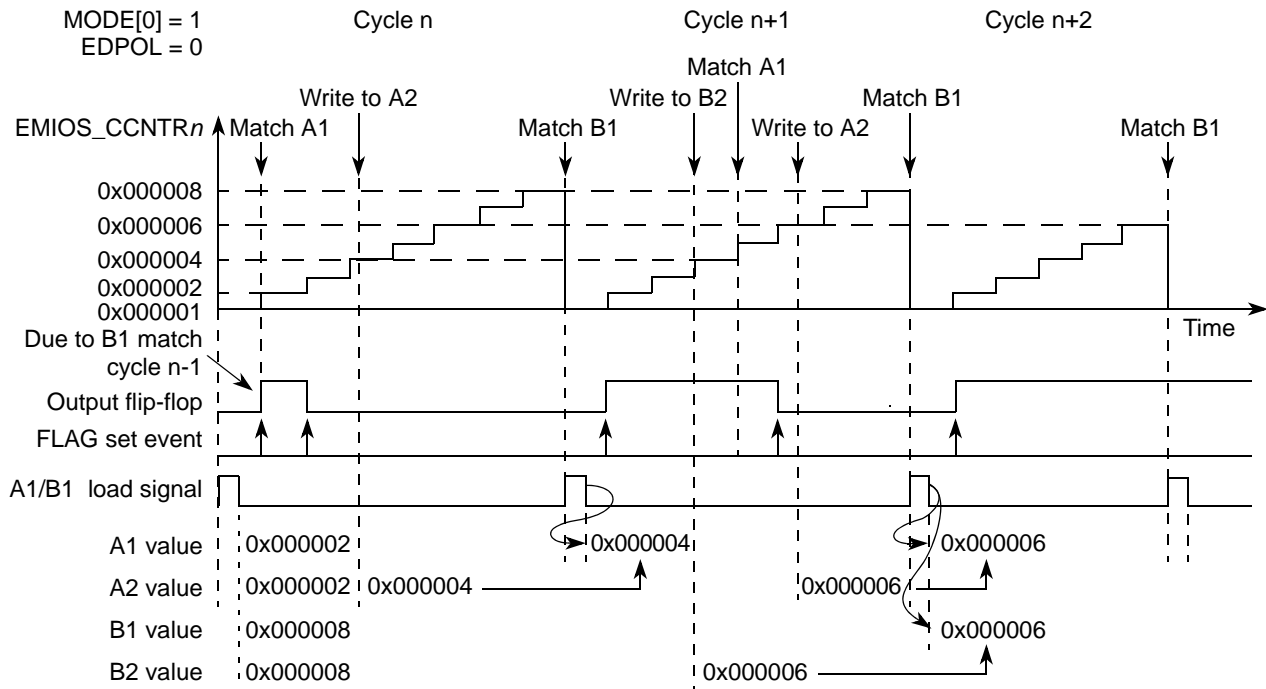

Figure 16-46. eMIOS OPWFMB Mode Example — A1/B1 Updates and Flags

Figure 16-47 shows the operation of the output disable feature in OPWFMB mode. Unlike OPWFM mode, the output disable forces the channel output flip-flop to the EDPOL bit value. This functionality targets applications that use active high signals and a high to low transition at A1 match. For such cases, clear EDPOL to 0.

Figure 16-47. eMIOS OPWFMB Mode Example — Active Output Disable

The output disable has a synchronous operation, meaning that the assertion of the output disable input signal causes the channel output flip-flop to transition to EDPOL at the next system clock cycle. If the output disable input is negated, the output flip-flop transitions at the following A1 or B1 match.

In Figure 16-47 it is assumed that the output disable input is enabled and selected for the channel (refer to Section 16.3.1.7, “eMIOS Channel Control Register (EMIOS_CCRn),” for a detailed description of the ODIS and ODISSL bits and selection of the output disable inputs).

The FORCMA and FORCMB bits allow the software to force the output flip-flop to the level corresponding to a match on comparators A or B respectively. Similar to a B1 match, FORCMB clears the internal counter. The FLAG bit is not set when the FORCMA or FORCMB bits are set.

Figure 16-48 illustrates the generation of 100% and 0% duty cycle signals. It is assumed that EDPOL = 0 and the prescaler ratio is 1. Initially A1 = 0x000008 and B1 = 0x000008. In this case, a B1 match has precedence over an A1 match, thus the output flip-flop is set to the complement of EDPOL. This cycle corresponds to a 100% duty cycle signal. The same output signal can be generated for any A1 value greater than or equal to B1.

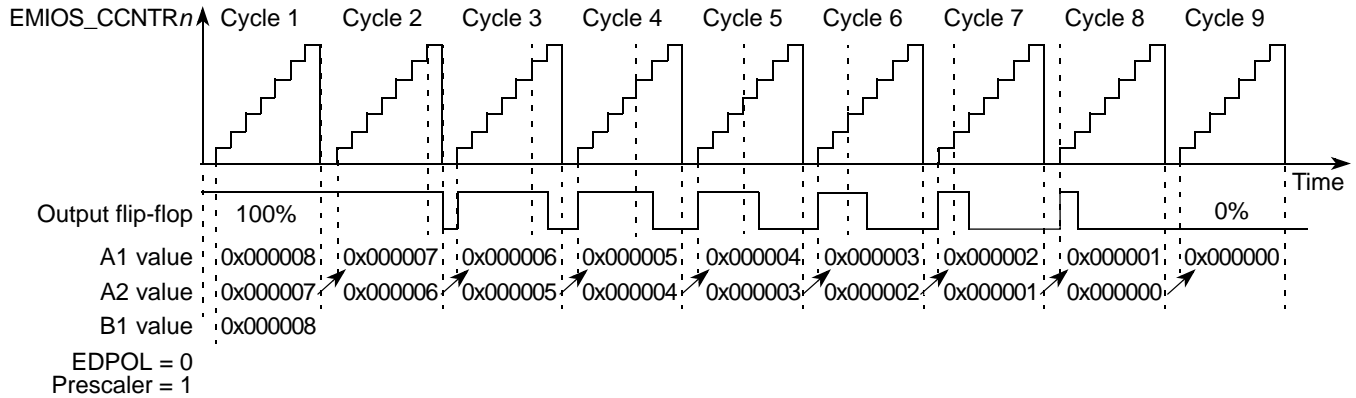

Figure 16-48. eMIOS OPWFMB Mode Example — 100% to 0% Duty Cycle

A 0% duty cycle signal is generated if A1 = 0 as shown in Figure 16-48 cycle 9. In this case the B1 = 0x000008 match from cycle 8 occurs at the same time as the A1 = 0x000000 match from cycle 9. Refer to Figure 16-45 for a description of A1 and B1 match generation for a case where A1 match has precedence over B1 match and the output signal transitions to EDPOL.

16.4.4.4.17 Center-Aligned Output Pulse-Width Modulation Buffered Mode (OPWMCB)

The following table lists the center-aligned output pulse-width modulation buffered mode settings:

Table 16-30. OPWMCB Operating Modes

MODE[0:6]	Unified Channel OPWMCB Operating Mode
0b1011100	Center-aligned output pulse-width modulation, buffered. FLAG set on trailing edge, trailing edge dead-time.
0b1011101	Center-aligned output pulse-width modulation, buffered. FLAG set on trailing edge, leading edge dead-time.
0b1011110	Center-aligned output pulse-width modulation, buffered. FLAG set on both edges, trailing edge dead-time.
0b1011111	Center-aligned output pulse-width modulation, buffered. FLAG set on both edges, leading edge dead-time.

This mode generates a center-aligned PWM with dead time insertion on the leading or trailing edge. A1 and B1 registers are double buffered to allow smooth output signal generation when changing A2 or B2 values asynchronously.

The selected counter bus for a channel configured to OPWMCB mode must be another channel running in MCB up/down counter mode (refer to Section 16.4.4.4.15, “Modulus Counter Buffered Mode (MCB)”). Register A1 contains the ideal duty cycle for the PWM signal and is compared with the selected time base. Register B1 contains the dead time value and is compared against the internal counter. For a leading edge

dead time insertion, the output PWM duty cycle is equal to the difference between register A1 and register B1, and for a trailing edge dead time insertion, the output PWM duty cycle is equal to the sum of register A1 and register B1. The MODE[6] bit selects between trailing and leading dead time insertion, respectively.

NOTE

Synchronize the internal prescaler of the OPWMCB channel with the MCB channel prescaler and set them to the same value. This allows the A1 and B1 registers to represent the same time scale for duty cycle and dead time insertion.

Figure 16-49 illustrates loading of the A1 and B1 registers, which occurs when the selected counter bus reaches the value one. This counter value defines the cycle boundary. Values written to A2 or B2 within cycle (*n*) are loaded into A1 or B1 registers and are used to generate matches in cycle (*n*+1).

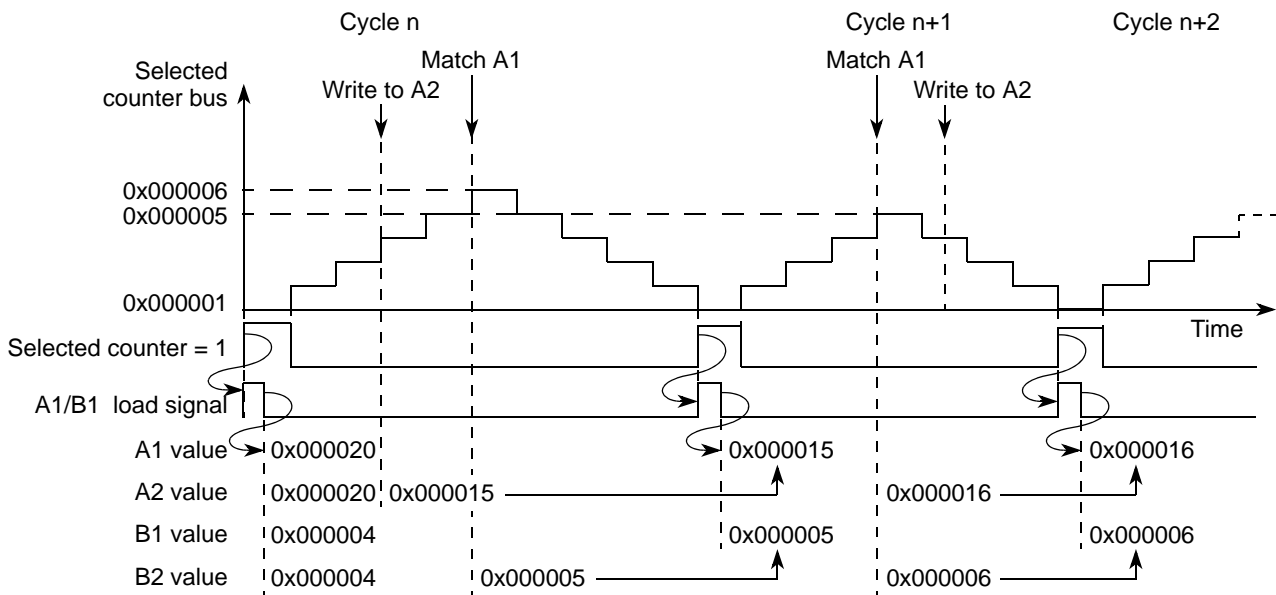

Figure 16-49. eMIOS OPWMCB Mode Example — A1/B1 Register Loading

The EMIOS_OUDR[n] bit can be used to disable the A1 and B1 updates, thus allowing the loading of these registers to be synchronized with the load of A1 or B1 registers in others channels. By using the update disable bit, the A1 and B1 registers can be updated in the same counter cycle.

In this mode A1 matches set the internal counter to one. When operating with leading edge dead time insertion, the first A1 match resets the internal counter to 0x000001. When a match occurs between register B1 and the internal time base, the output flip-flop is set to the value of the EDPOL bit. In the following match between A1 and the selected time base, the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously.

Figure 16-50 shows two cycles of a center-aligned PWM signal. Both A1 and B1 register values are changing within the same cycle, which allows the duty cycle and dead time values to be changed at simultaneously.

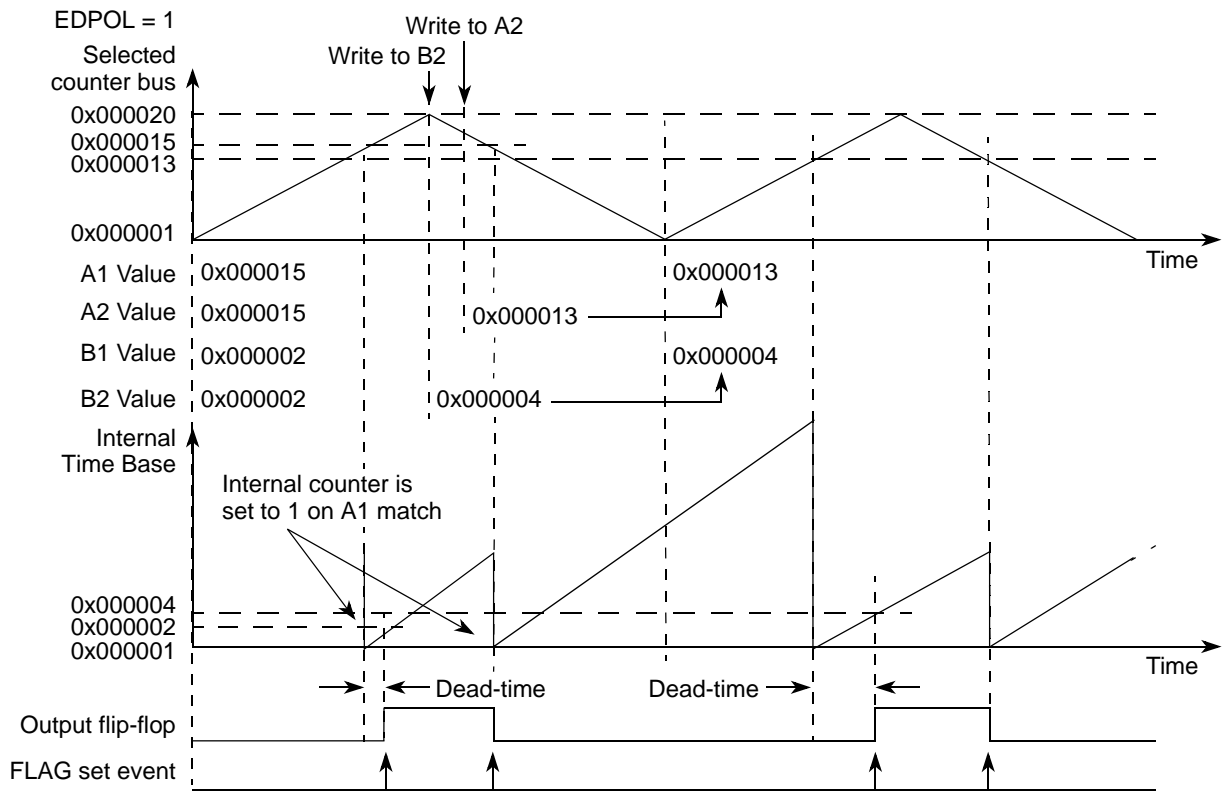

Figure 16-50. eMIOS PWMCB Mode Example — Lead Dead Time Insertion

As shown in Figure 16-51, when operating with trailing edge dead time insertion the first match between A1 and the selected time base sets the output flip-flop to the value of the EDPOL bit and resets the internal counter to 0x000001. In the second match between register A1 and the selected time base, the internal counter is reset to 0x000001 and B1 matches are enabled. When the match between register B1 and the selected time base occurs the output flip-flop is set to the complement of the EDPOL bit. This sequence repeats continuously.

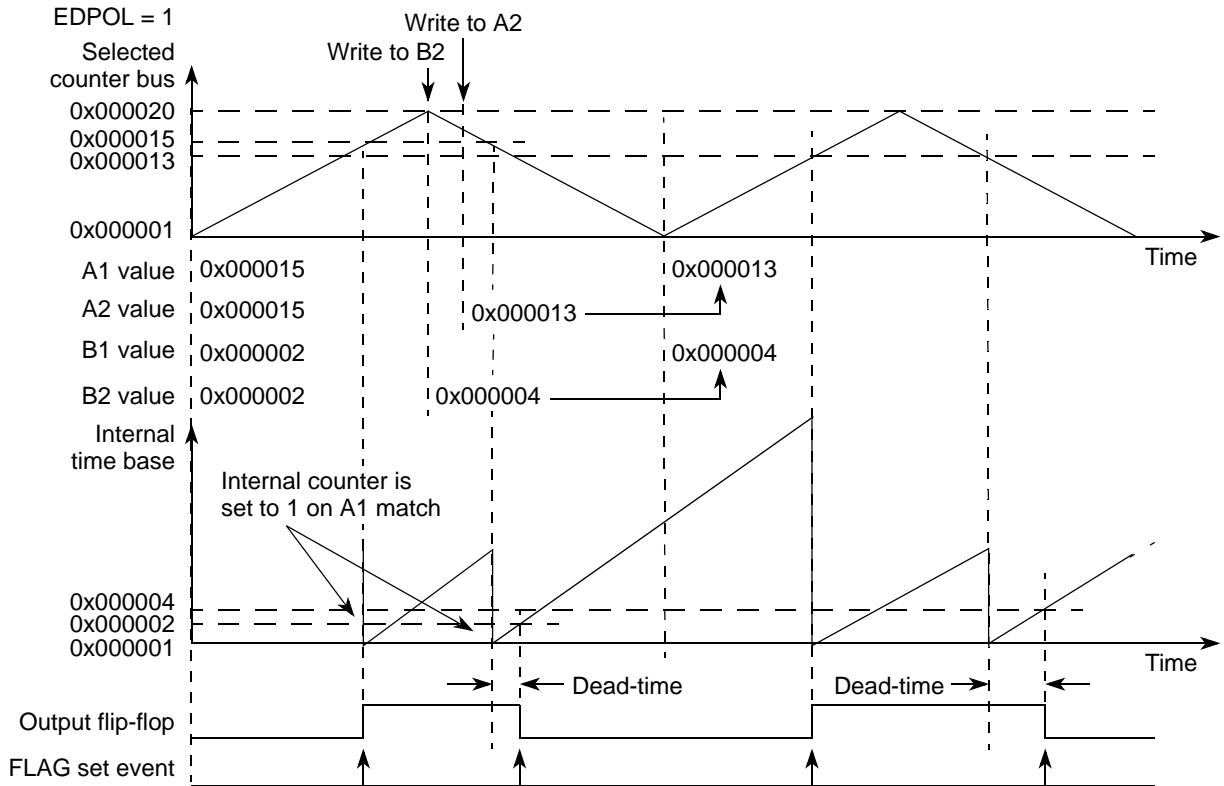

Figure 16-51. eMIOS PWMCB Mode Example — Trailing Dead Time Insertion

FLAG can be generated in the trailing edge of the output PWM signal when MODE[5] is cleared, or on both edges when MODE[5] is set. If subsequent matches occur on A and B, the PWM pulses continue to be generated, regardless of the state of the FLAG bit.

NOTE

In OPWMCB mode, FORCMA and FORCMB do not have the same behavior as a regular match. Instead they force the output flip-flop to a constant value which depends upon the selected dead time insertion mode, lead or trail and the value of the EDPOL bit.

FORCMA has different behaviors depending on the selected dead time insertion mode. In leading dead time insertion mode, writing one to FORCMA sets the output flip-flop to the compliment of EDPOL. In trailing dead time insertion mode, the output flip-flop is forced to the value of EDPOL.

If FORCMB is set, the output flip-flop value depends on the selected dead time insertion mode. In leading dead time insertion mode, FORCMB sets the output flip-flop to the value of EDPOL. In trailing dead time insertion mode, the output flip-flop is forced to the compliment of EDPOL.

NOTE

Setting the FORCMA bit does not reset the internal time base to 0x000001 as a regular A1 match does. FORCMA and FORCMB have the same behavior even in freeze or normal mode regarding the output flip-flop transition.

The FLAG bit is not set in the case of the FORCMA, FORCMB or both bits being set at the same time.

When FORCMA and FORCMB are both set, the output flip-flop is set to the compliment of the EDPOL bit. This is equivalent to FORCMA having precedence over FORCMB when lead dead time insertion is selected and FORCMB having precedence over FORCMA when trailing dead time insertion is selected.

Duty cycles from 0% to 100% can be generated by setting appropriate A1 and B1 values relative to the period of the external time base. Setting $A1 = 1$ or $A1 = 0$ generates a 100% duty cycle waveform. If $A1 > \text{period} \div 2$, where period refers to the selected counter bus period, then a 0% duty cycle is produced. Assuming EDPOL is one and OPWMCB mode with trailing dead time insertion mode is selected, 100% duty cycle signals can be generated if B1 occurs at or after the cycle boundary (external counter = 1).

NOTE

A special case occurs when A1 is set to the external counter bus period $\div 2$, which is the maximum value of the external counter. In this case the output flip-flop is constantly set to the EDPOL bit value.

Internal channel logic prevents matches from one cycle to propagate to the next cycle. In trailing dead time insertion mode, a B1 match from cycle (n) could eventually cross the cycle boundary and occur in cycle ($n+1$). In this case the B1 match is masked out and does not cause the output flip-flop to transition. Therefore matches in cycle ($n+1$) are not affected by the late B1 matches from cycle (n).

Figure 16-52 shows a 100% duty cycle output signal generated by setting $A1 = 4$ and $B1 = 3$. In this case the trailing edge is positioned at the boundary of cycle (n+1), which is actually considered to belong to cycle (n+2) and therefore does not cause the output flip-flop to transition.

Figure 16-52. eMIOS PWMCB Mode Example — 100% Duty Cycle ($A1 = 4$, $B1 = 3$)

The output disable input, if enabled, causes the output flip-flop to transition to the compliment of EDPOL. This allows to the channel output flip-flop to be forced to a safety state. The internal channel matches continue to occur in this case, thus generating flags. When the output disable is negated, the channel output flip-flop is again controlled by A1 and B1 matches. This process is synchronous, meaning that the output channel pin transitions only occur on system clock edges.

Like in OPWMB and OPWFMB modes, the match signal used to set or clear the channel output flip-flop is generated on the negation of the channel comparator output signal which compares the selected time base with A1 or B1. Refer to Figure 16-44, which illustrates the delay from matches to output flip-flop transition in OPWFMB mode.

16.4.4.4.18 Output Pulse-Width Modulation, Buffered Mode (OPWMB)

The following table lists the output pulse-width modulation buffered mode settings:

Table 16-31. OPWMB Operating Modes

MODE[0:6]	Unified Channel OPWMB Operating Mode
0b1100000	Output pulse-width modulation, buffered. FLAG set on second match.
0b1100001	Reserved
0b1100010	Output pulse-width modulation, buffered. FLAG set on both matches.

OPWMB mode is used to generate pulses with programmable leading and trailing edge placement. An external counter is selected from one of the counter buses. The A1 register value defines the first edge and B1 defines the second edge. The output signal polarity is defined by the EDPOL bit. If EDPOL is zero, a negative edge occurs when A1 matches the selected counter bus and a positive edge occurs when B1 matches the selected counter bus.

The A1 and B1 registers are double buffered and updated from A2 and B2, respectively, at the cycle boundary. The load operation is similar to the OPWFMB mode.

Refer to [Figure 16-46](#) for more information on A1 and B1 register updates.

Flags are generated at B1 matches when MODE[5] is cleared, or on both A1 and B1 matches when MODE[5] is set. If subsequent matches occur on comparators A and B, the PWM pulses continue to be generated regardless of the state of the FLAG bit.

The FORCMA and FORCMB bits allow software to force the output flip-flop to the level corresponding to a match on A1 or B1 respectively. FLAG is not set by the FORCMA and FORCMB operations.

The following rules apply to the OPWMB mode:

- B1 matches have precedence over A1 matches if they occur at the same time within the same counter cycle.
- A1 = 0 match from cycle (n) has precedence over a B1 match from cycle ($n-1$).
- A1 matches are masked if they occur after a B1 match within the same cycle.
- Values written to A2 or B2 on cycle (n) are loaded to A1 or B1 at the following cycle boundary (assuming EMIOS_OUDR[n] is not asserted). Thus the new values are used for A1 and B1 matches in cycle ($n+1$).

Figure 16-53 illustrates operation in OPWMB mode with A1/B1 matches and the transition of the channel output flip-flop. In this example EDPOL is zero.

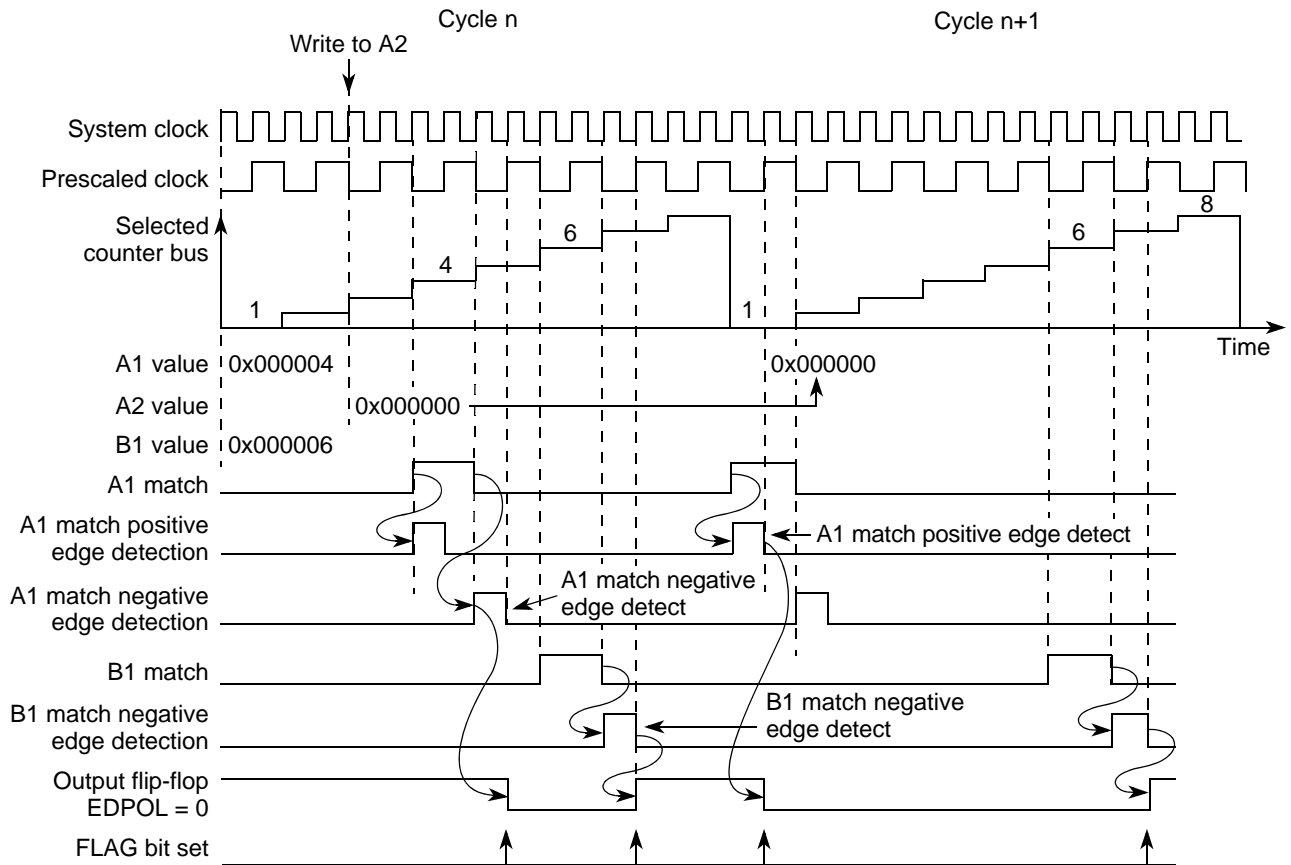

Figure 16-53. eMIOS OPWMB Mode Example — Matches and Flags

The output flip-flop transitions are based on the negative edges of the A1 and B1 match signals. Figure 16-53 shows the value of A1 being set to zero in cycle (n+1). In this case the match positive edge is used instead of the negative edge to transition the output flip-flop.

Figure 16-54 illustrates the channel operation for 0% duty cycle. The A1 match signal positive edge occurs at the same time as the B1 = 8 signal negative edge. In this case the A1 match has precedence over the B1 match, causing the output flip-flop to remain at the EDPOL value, thus generating a 0% duty cycle.

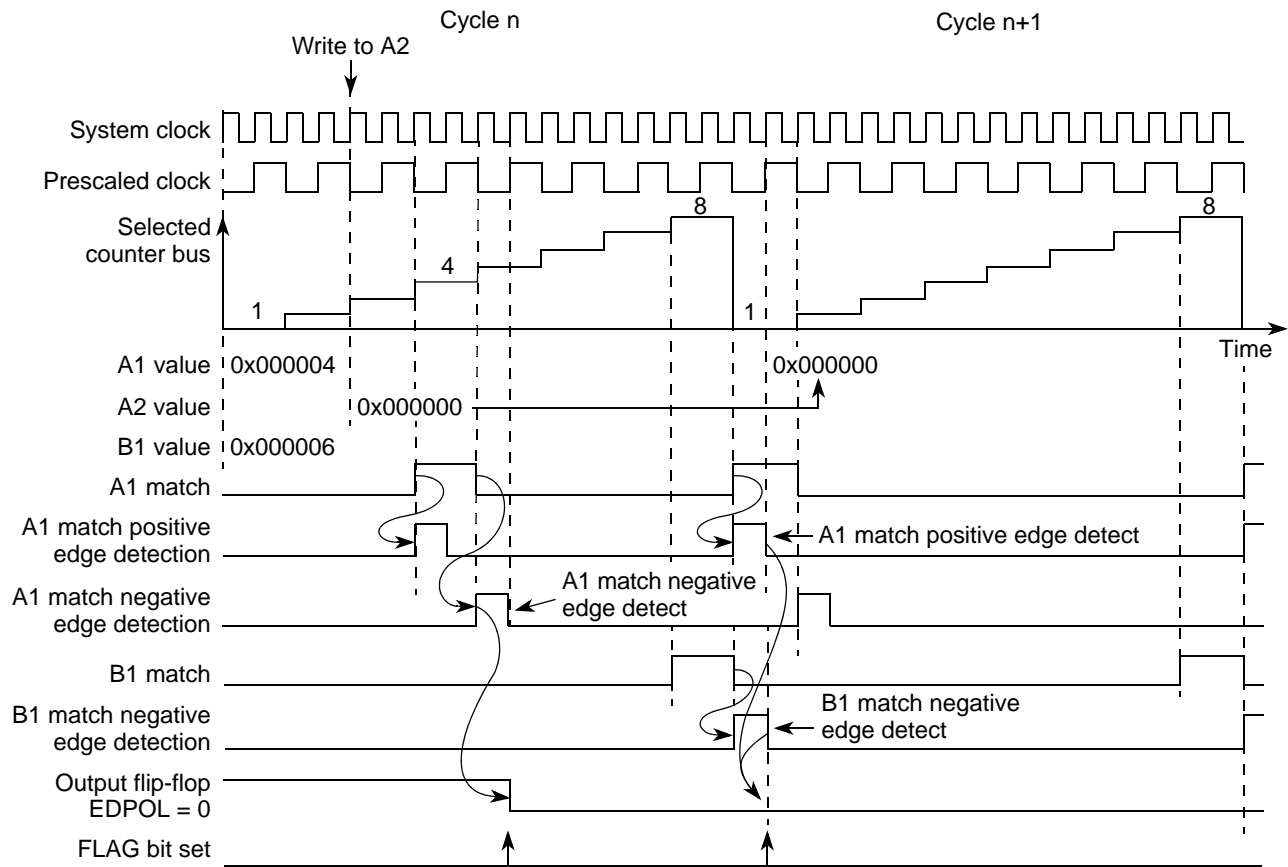

Figure 16-54. eMIOS OPWMB Mode Example — 0% Duty Cycle

Figure 16-55 shows the operation of the OPWMB mode with the output disable signal asserted. The output disable forces a transition in the output flip-flop to the EDPOL bit value. After the output disable is negated, the output flip-flop is allowed to transition at the next A1 or B1 match. The output disable does not modify the flag bit behavior. There is one system clock delay between the assertion of the output disable signal and the transition of the output flip-flop.

Figure 16-55. eMIOS OPWMB Mode Example — Active Output Disable

Figure 16-56 shows a waveform changing from 100% to 0% duty cycle. In this case EDPOL is zero and B1 is set to the same value as the period of the selected external time base.

Figure 16-56. eMIOS OPWMB Mode Example — 100% to 0% Duty Cycle

In Figure 16-56 if B1 is set to a value lower than 0x000008 it is not possible to achieve 0% duty cycle by only changing A1 register value. Since B1 matches have precedence over A1 matches, the output flip-flop transitions to the compliment of EDPOL at B1 matches. In this example, if B1 = 0x000009, a B1 match does not occur, and thus a 0% duty cycle signal is generated.

16.5 Initialization/Application Information

Upon reset, all eMIOS unified channels default to general purpose inputs (GPIO input mode).

16.5.1 Considerations on Changing a UC Mode

Before changing an operating mode, program the UC to GPIO mode, and update EMIOS_CADR_n and EMIOS_CBDR_n with the values for the next operating mode. The EMIOS_CCR_n can be written with the next operating mode. If a UC is changed from one mode to another without performing this procedure, the first operating cycle of the selected time base is unpredictable.

NOTE

When interrupts are enabled and an interrupt is generated, clear the FLAG bits before exiting the interrupt service routine.

16.5.2 Generating Correlated Output Signals

Correlated output signals can be generated by all output operating modes. Bits ODIS_n can be used to control the update of these output signals.

To guarantee that the internal counters of correlated channels are incremented in the same clock cycle, the internal prescalers must be set up before enabling the global prescaler. If the internal prescalers are set after enabling the global prescaler, the internal counters can increment in the same ratio, but at a different clock cycle.

Drive output disable input signals with the EMIOS_Flag_Out signals of some UCs running in SAIC mode. When an output disable condition occurs, the software interrupt routine must service the output channels before servicing the channels running SAIC. This procedure avoid glitches in the output pins.

16.5.3 Time Base Generation

For all channel operation modes that generate a time base (MC, OPWFM, OPWM, MCB, OPWFMB and OPWMB), the internal counter rate can be modified by configuring the clock prescaler ratio. The clock prescaler can use several ratios calculated as:

$$\text{Ratio} = (\text{GPRES} + 1) \times (\text{UCPRE} + 1)$$

The prescaled clocks in [Figure 16-58](#), [Figure 16-59](#), and [Figure 16-57](#) illustrate the time base generation mechanism. [Figure 16-60](#) shows the time base generation when using the internal clock set and clear on match start.

If the prescaler ratio is 9, the prescaled clock pulses every nine clock cycles and the internal counter increments every nine clock cycles. The high pulse allows the EMIOS_CCNTR n to increment as long as no other conditions disable this counter. The match signal is generated by pulsing every time the internal counter matches the programmed match value. For a programmed match value, the time base-period becomes smaller as the prescaler ratio increases.

Figure 16-57 shows the prescaler ratio equal to 1, therefore the prescaled clock remains high and continuously enables the internal counter (EMIOS_CCNTR n):

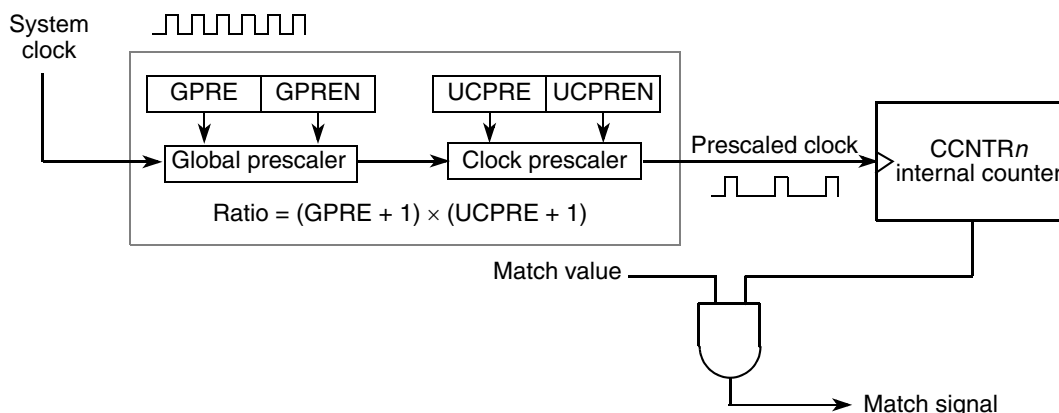

Figure 16-57. eMIOS Time Base Generation Block Diagram

Figure 16-58 shows the prescaler ratio equal to one, therefore the prescaled clock remains high and continuously enables the internal counter (EMIOS_CCNTR n):

Figure 16-58. eMIOS Time Base Example — Fastest Prescaler Ratio = 1

Figure 16-59 shows the prescaler ratio equal to three, therefore, the prescaled clock pulses every three clock cycles and the internal counter increments every three clock cycles:

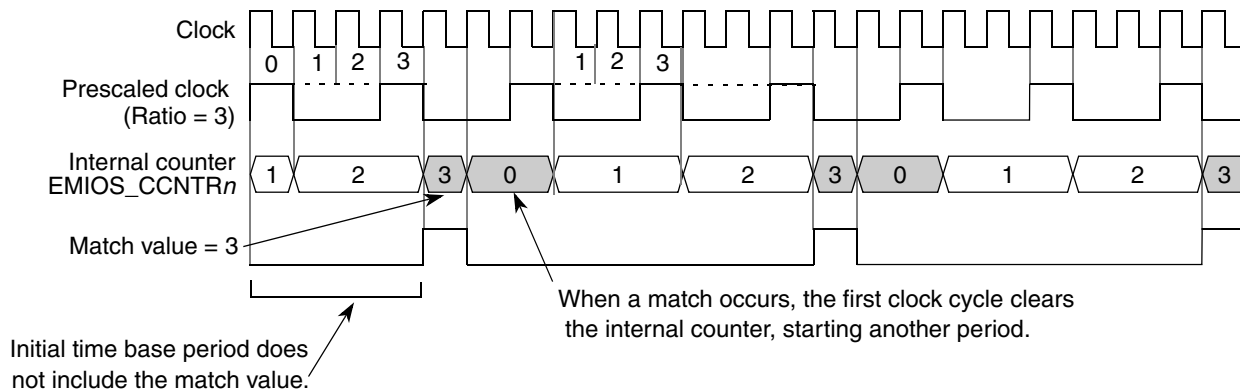

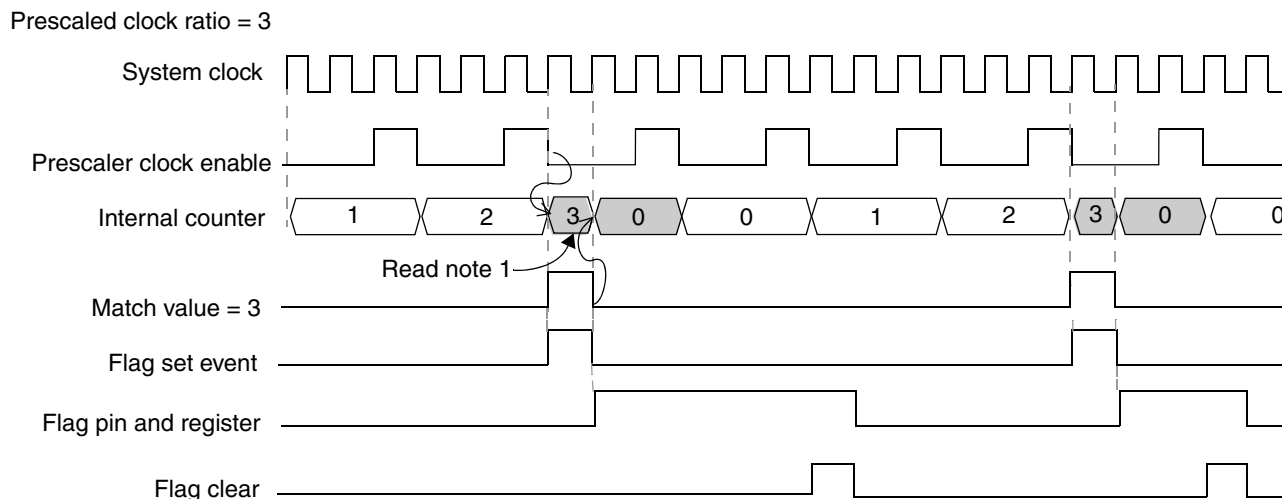

Figure 16-59. eMIOS Time Base Example — Prescale Ratio = 3, Match Value = 3

Figure 16-60 shows an example of time-base generation using the internal clock with clear on match start:

Note 1: When a match occurs, the first clock cycle is used to clear the internal counter. The internal counter starts counting after the second edge of the prescaled clock.

Figure 16-60. Time Base Generation Using the Internal Clock with Clear on Match Start

16.6 Document Revision History

Table 16-32. Changes Between MPC5565RM Revisions 0.1 and 1

Added Table 16-14 “GPIO Operating Mode” to the section titled General Purpose Input/Output Mode.
Added Table 16-23 “MC Operating Mode” to Modulus Counter Mode (MC) section.
Added Table 16-24 “OPWFM Operating Mode” to Output pulse-width Frequency Modulation (OPWFM) section.
Added Operating Mode tables for all modes.
Added this first sentence to the OPWFM mode: <ul style="list-style-type: none"> In this mode, the duty cycle is (register A1 + 1) and the period is (register B1 + 1).
Changed register addresses to byte format throughout (i.e., 0x14 -> 0x0014)
Table 16-1 “eMIOS Operating Modes,” Moved the detailed descriptions into the table for readability.
Figure 16-36 Changed two occurrences of \$000200 to 0x000200.
Added Figure 16-60 <i>Time Base Generation Using the Internal Clock with Clear on Match Start</i> Section 16.5.3, “Time Base Generation” Changed <ul style="list-style-type: none"> From: ‘Note that for the same programmed match value, the period is shorter when using a prescaler ratio greater than one.’ To: ‘For a programmed match value, the time base-period becomes smaller as the prescaler ratio increases.’

Chapter 17

Enhanced Time Processing Unit (eTPU)

17.1 Introduction

The enhanced time processing unit (eTPU) operates in parallel with the MPC5565 core (CPU) to:

- Execute programs independently from the host core
- Detect and precisely record the timing of input events
- Generate complex output waveforms
- Enhances the CPU with time processing without requiring real-time host processing

The host core setup and service times for each input and output event are greatly minimized. The MPC5565 contains one eTPU.

The eTPU improves the performance of the device by providing high-resolution timing:

- eTPU dedicated channels include two match and two capture registers (TPUs had one).
- eTPU engines are optimized to service channel hardware
- Fast instruction execution rate of the eTPU engine reduces service time

Because responding to hardware service requests is primarily done by the eTPU engine, the host is free to handle higher level operations.

17.1.1 MPC5565 eTPU Implementation

For more detailed information regarding the eTPU module and compiler, refer to the *Enhanced Time Processing (eTPU) Reference Manual*. The MPC5565 contains a specific implementation of the eTPU's full functionality. This chapter provides an overview of the eTPU module and details its differences from the full instantiation of the module that include:

- 2.5 KB of shared data memory (SDM). This memory is also referred to as eTPU shared parameter (SP) RAM, or (SPRAM).
- 12 KB of shared code memory (SCM).
- MPC5565 has one eTPU engine: eTPU A
- The eTPU debug interface is built into the device's debug module. Refer to Section 10.2.1 of the *eTPU Reference Manual* for details on eTPU debug.
- Data transfer requests are implemented as a single DMA request to the device's DMA controller. All 32 channels' data transfer request signals are logically OR'd to produce the single DMA request.
- I/O channel pairs can be shared on a common pin. The output buffer enable (OBE) is not used in the device. The outputs are enabled in the SIU; refer to [Chapter 6, "System Integration Unit \(SIU\)."](#)

Because of the differences between the MPC5565 implementation of the eTPU and the full eTPU, full register bit descriptions are included within this chapter as well as in the *Enhanced Time Processing (eTPU) Reference Manual*.

17.1.2 Block Diagram

Figure 17-1 shows a top-level block diagram of a single eTPU engine in the MPC5565.

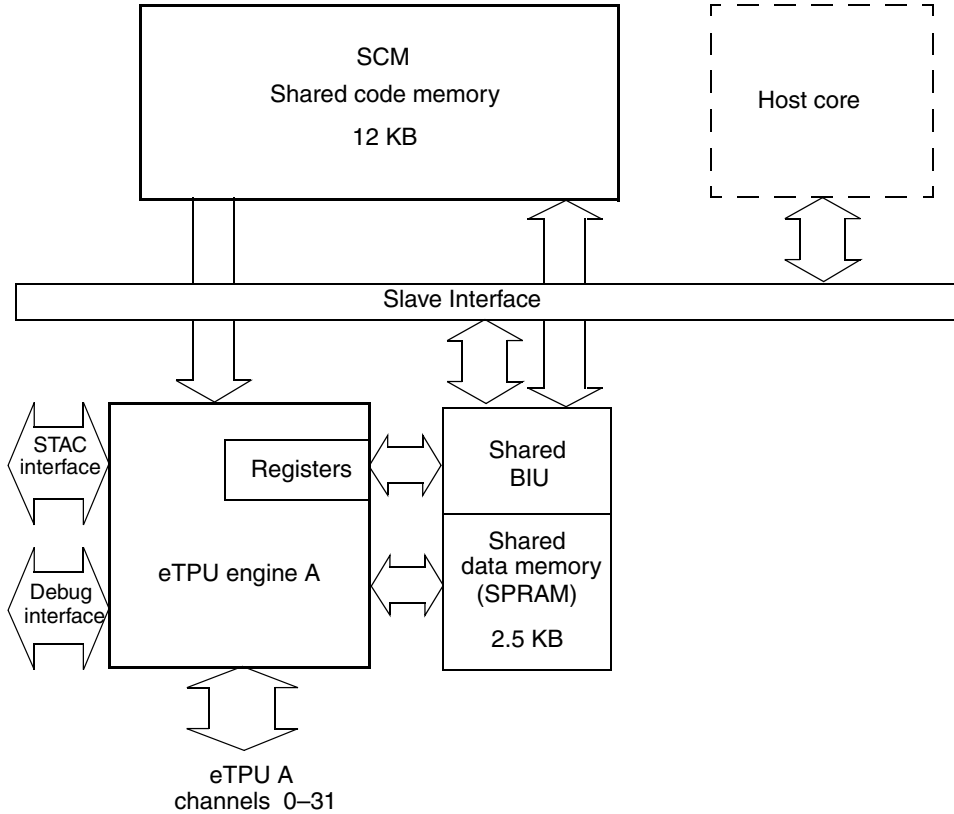

Figure 17-1. Single eTPU Block Diagram

Figure 17-2 shows the block diagram for the eTPU engine.

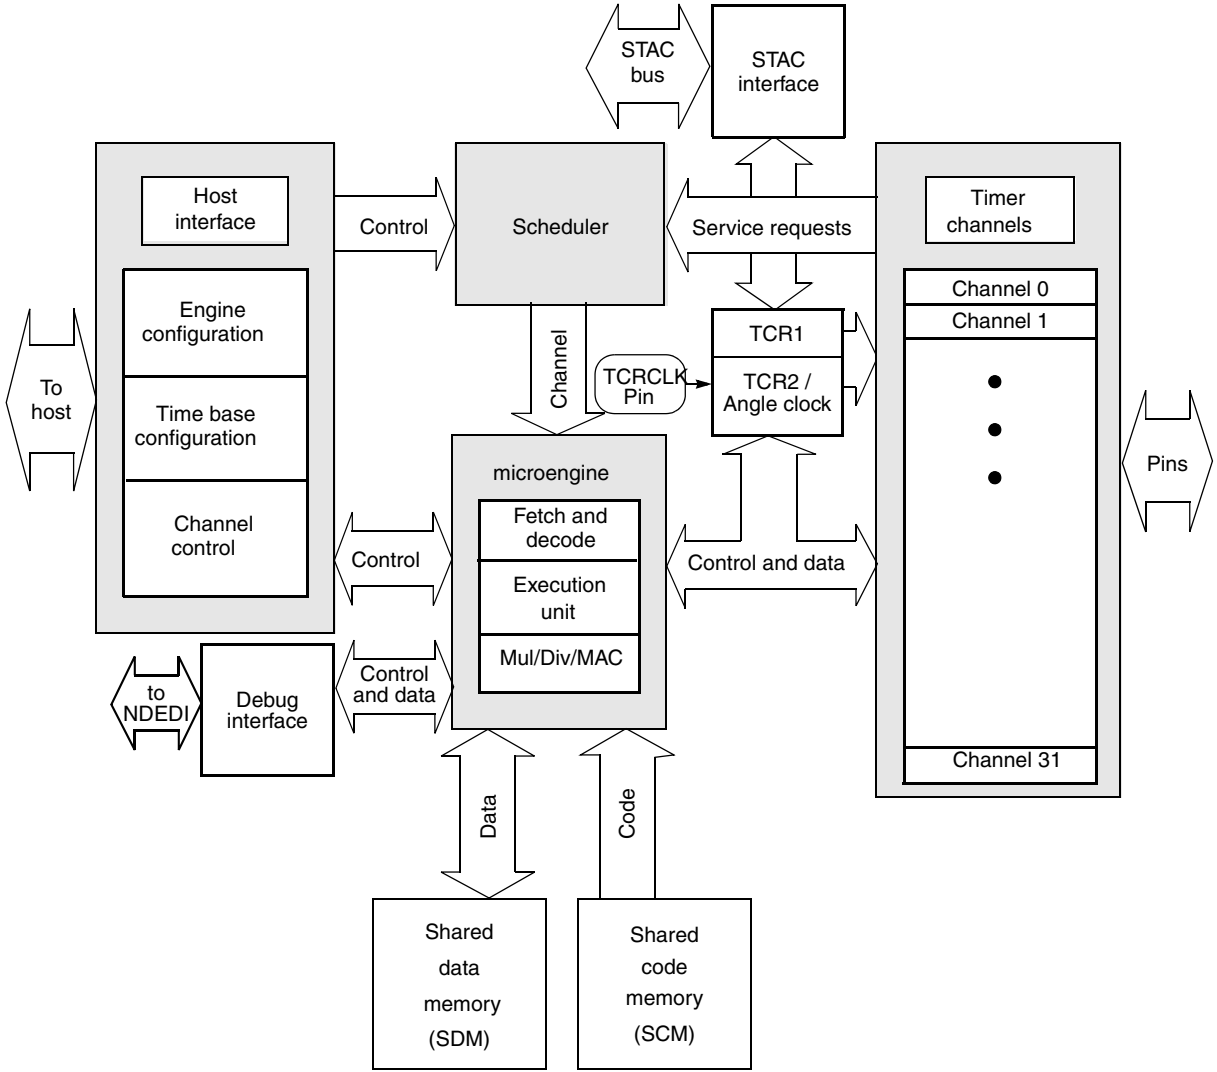

Figure 17-2. eTPU Engine Block Diagram

17.1.3 eTPU Operation Overview

The eTPU is a real-time microprocessed subsystem. Therefore, it runs microengine code from instruction memory (SCM) to handle specific events and accesses data memory (SDM) for parameters, work data, and application state information. Events can originate from I/O channels (due to pin transitions and/or time base matches), device core requests, or inter-channel requests. Events that call for local eTPU processing activate the microengine by issuing a service request. The service request microcode can send an interrupt to the device core, but cannot directly interrupt the core using I/O channel events.

Each channel has a function that consists of a set of microengine routines, called threads, that service eTPU requests which defines the channel’s behavior. Function routines, which reside in the SCM, are also used to configure the channel. A function can be assigned to several channels, but a channel can only process

one function at a given moment. The eTPU can change the function assigned to a channel if the channel is reconfigured by the device core. The device core configures the function to channel assignments.

The following eTPU hardware supplies resource sharing features that support concurrency:

- A hardware scheduler dispatches the service request microengine routines based on a set of priorities defined by the device's core. Each channel has its own unique priority assignment that primarily depends on CPU assignment. The channel's number is an inherent property also used to determine priority.
- A service request routine cannot be interrupted by another service request until it ends, that is, until an end instruction is executed. This sequence of uninterrupted instruction execution is called a thread. The core can terminate the thread by writing 1 to the FEND bit in the ETPU_ECR register.
- Channel-specific contexts (registers and flags) are automatically switched between the end of a thread and the beginning of the next one.
- SDM arbitration, a dual-parameter coherency controller, and semaphores can be used to ensure coherent access to eTPU data shared by both eTPU engines and the device core.

17.1.4 eTPU Engine

The eTPU engine processes input pin transitions and generates output pin waveforms. These events are triggered by eTPU timers (time bases) that are driven by a system clock to give absolute time control or by an asynchronous counter, such as an angle clock that is tracking the angle of a rotating shaft.

The eTPU engine consists of the following blocks: 32 independent timer channels, a task scheduler, a host interface, and a microprocessor (hereinafter called a microengine) that has dedicated hardware for input signal processing and output signal generation over the 32 I/O channels. Each channel can choose between two 24-bit counter registers for a time base.

The microengines fetch microinstructions from shared code memory (SCM). eTPU application parameters and global and local variables, referred to as work data, are held in 32-bit shared data memory (SDM), which is also used for passing information between the device's core and microengine. The bus interface unit (BIU) allows the device's core to access eTPU registers, SDM, and SCM.

17.1.4.1 Time Bases

The eTPU engine has two 24-bit count registers TCR1 and TCR2 that provide reference time bases for all match and input capture events. Prescalers for both time bases are controlled by the device core through bit fields in the eTPU engine configuration registers.

The values for each of TCR1 and TCR2 counter registers can be independently derived from the system clock or from an external input via the TCRCLK pin. In addition, the TCR2 time base can be derived from special angle-clock hardware that enables implementing angle-based functions. This feature is added to support advanced angle-based engine control applications.

The TCRs can also drive an eMIOS time base through the shared time and counter (STAC) bus, or they can be written by eTPU function software.

17.1.4.2 eTPU Timer Channels

The eTPU engine has 32 identical, independent channels. Each channel corresponds to an input/output signal pair. Every channel has access to two 24-bit counter registers, TCR1 and TCR2.

Each channel consists of event logic which supports a total of four events, two capture and two match events. The event logic contains two 24-bit capture registers and two 24-bit match registers. The match registers are compared to a selected TCR by greater-than-or-equal-to and equal-only comparators. The match and compare register pairs enable many combinations of single and double-action functions.

The channel configuration can be changed by the microengine. Each channel can perform double capture, double match or a variety of other capture-match combinations. Service requests can be generated on one or both of the match events and/or on one of the capture events.

Digital filters that have different filtering modes are provided for the input signals.

Every channel can use any time base or angle counter for either match or capture operation. For example, a match on TCR1 can capture the value of TCR2. The channels can request service from the microengine due to recognized pin transitions (input events) or time base matches.

Every eTPU channel can be configured with the following combinations:

- Single input capture, no match (TPU3 functionality)
- Single input capture with single match time-out (TPU3 functionality)
- Single input capture with double match time-out with several double match submodes
- Double input capture with single or double match time-out with several double match submodes
- Single output match (TPU3 functionality)
- Double output match with several double match submodes
- Input-dependent output generation

The double match functionality has various combinations for generation of service request and determining pin actions.

17.1.4.3 Host Interface

The engine's host interface allows the device core to control the operation of the eTPU. In order for the eTPU to start operation, the device core must initialize the eTPU by writing to the appropriate host interface registers to assign a function and priority to each channel. In addition, the device core writes to the host service request and channel configuration registers to further define operation for each initialized channel.

NOTE

The host transfers the code image for the eTPU microcode to the SCM, then the host enables eTPU access to the SCM (which also disables host access).

17.1.4.4 Shared Data Memory (SDM)

The SDM works as data RAM that can be accessed by the device core and up to two eTPU engines. This memory is used for either:

- Information transfer between the device core and the eTPU
- Data storage for the eTPU microcode program
- Communication between the two eTPU engines

The SDM width is 32 bits, and is accessible by the host in any of the three formats: byte, 16-bit, or 32-bit. The eTPU can access the SDM's full 32 bits, lower 24 bits or upper byte (8-bit). The host can also access the SDM space mirrored in an alternate area with parameter sign extension (PSE). PSE allows accessing 24-bit data as 32-bit sign-extended data without using the device's bandwidth to extend the data.

Parameter sign extension accesses differ from the usual host accesses to the original SDM area:

Writes are effective only to the lower 3-bytes of a word: the word's most significant byte (byte address) is kept unaltered in SDM.

Figure 17-3. SDM PSE Area Write

NOTE

For the most significant byte, the word format is big endian.

Reads return the lower 3-bytes of a word sign-extended to 32 bits; the most significant bit of the word's second most significant byte (byte addresses) is copied in all 8 bits of the most significant read byte.

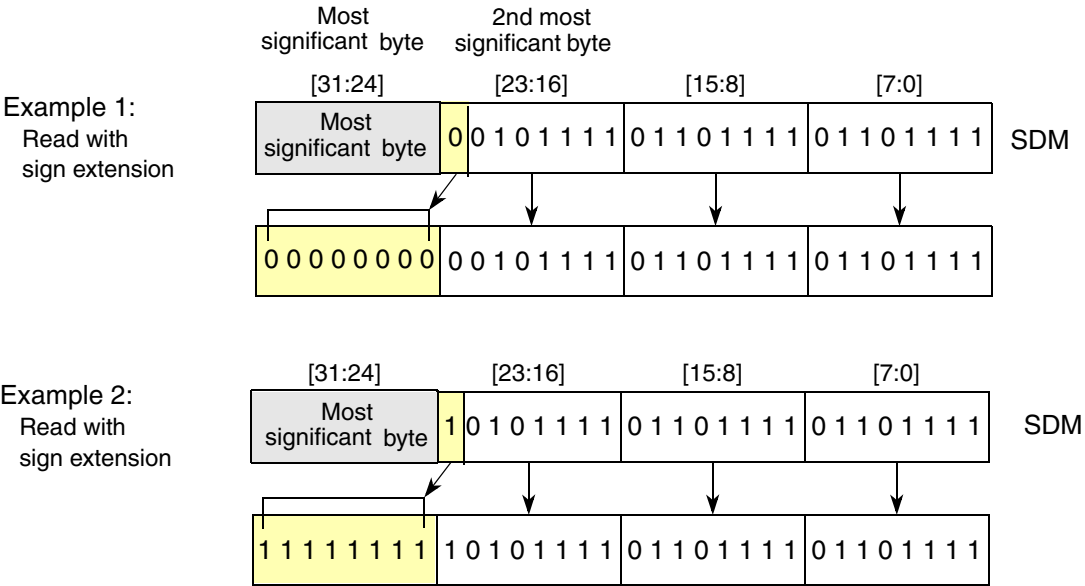

Figure 17-4. PSE Accesses

Each eTPU channel can be associated with a variable number of parameters located in the SDM, according to its selected function. In addition, the SDM can be fully shared between two eTPU engines, enabling communication between them. Each function can require a different number of parameters. During eTPU initialization the host has to program channel base addresses, allocating proper parameters for each channel according to its selected function.

In the host address space each parameter occupies four bytes (32 bits). eTPU usage of the upper byte is achieved by having a 32-bit preload (P) register that can access the upper byte, the lower 24 bits, or all the 32 bits. The microcode can switch between access sizes at any time.

17.1.4.5 Task Scheduler

As mentioned in [Section 17.1.3, “eTPU Operation Overview,”](#) every channel function is composed of one or more threads, and threads cannot be interrupted by host or channel events, such as channel servicing. The function of the task scheduler, therefore, is to recognize and prioritize the channels needing service and grant execution time to each channel. The time given to an individual thread for execution or service is called a time slot. The duration of a time slot is determined by the number of instructions executed in the thread plus SDM wait-states received, and varies in length. Although several channels can request service at the same time, the function threads must be executed serially.

At any time, an arbitrary number of channels can require service. The channel logic, eTPU microcode, or the host application notifies the scheduler by issuing a service request.

Out of reset, all channels are disabled. The device core makes a channel active by assigning it one of three priorities: high, middle, or low. The scheduler determines the order in which channels are serviced based on channel number and assigned priority. The priority mechanism, implemented in hardware, ensures that all requesting channels are serviced.

17.1.4.6 Microengine

The eTPU microengine is a simple RISC implementation that performs each instruction in a microcycle of two system clocks, while pre-fetching the next instruction through an instruction pipeline. Instruction execution time is constant for the arithmetic logic unit (ALU) unless it gets wait states from SDM arbitration.

Microcode is stored in shared code memory (SCM) that is 32 bits wide. The microengine instruction set provides basic arithmetic and logic operations, flow control (jumps and subroutine calls), SDM access, and channel configuration and control. The instruction formats are defined in such a way that allow particular combinations of two or three of these operations with unconflicting resources to be executed in parallel in the same microcycle, thus improving performance.

The microengine also has an independent multiply/divide/MAC unit that performs these complex operations in parallel with other microengine instructions.

Channel functionality is integrated into the instruction set through channel control operations and conditional branch operations, which support jumps/calls on channel-specific conditions. This allows quick and terse channel configuration and control code, contributing to reduced service time.

17.1.4.7 Debug Interface

Nexus level 3 debug support is available through the eTPU Nexus development interface (NDEDI). Refer to [Chapter 24, “Nexus Development Interface.”](#)

17.1.5 Features

The eTPU includes these distinctive features:

- Up to 32 channels for each eTPU engine: each channel is associated with an I/O signal pair
 - Enhanced input digital filters on the input pins for improved noise immunity. The eTPU digital filter can use two samples, three samples, or work in continuous mode.
 - Orthogonal channels, except for channel 0: each channel can perform any time function. Each time function can be assigned to more than one channel at a given time, so each signal can have any functionality. Channel 0 has the same capabilities of the others, but can also work with special angle counter logic.
 - A link service request allows activation of a channel thread by request of another channel, even between eTPU engines.
 - A host service request allows activation of a channel thread by the device core request.
 - Each channel has an event mechanism that supports single and double action functionality in various combinations. It includes two 24-bit capture registers, two 24-bit match registers, 24-bit greater-equal or equal-only comparator.

- Two independent 24-bit time bases for channel synchronization
 - The first time base can be clocked by the system clock with programmable prescaler division from 2 to 512 (in steps of 2).
 - The first time base can also be clocked by an external signal with programmable prescaler divisions of 1 to 256.
 - The second time base can be clocked by an external signal with programmable prescaler divisions from 1 to 64 or by the system clock divided by 8.
 - The second time base has a programmable prescaler that applies to all TCR2 clock inputs except the angle counter.
 - The second time base counter can work as an angle counter, enabling angle-based applications to match angle instead of time.
 - The second time base can alternatively be used as a pulse accumulator gated by an external signal.
 - Either time base can be written or read by either eTPU engine at any time.
 - Either time base can be read, but not written, by the host.
 - Both time bases can be exported or imported from engine to engine through the STAC (shared time and counter) bus.

NOTE

An engine cannot export/import to/from itself. An engine cannot import a time base and/or angle count if it is in angle mode.

- Event-triggered RISC processor (microengine)
 - 2-stage pipeline implementation (fetch and execution), with separate instruction memory (SCM) and data memory (SDM).
 - Two-system-clock microcycle fixed-length instruction execution for the ALU.
 - 12 KB of shared code memory (SCM).
 - 2.5 KB of shared data memory (SDM)
 - Instruction set with embedded channel support, including specialized channel control subinstructions and conditional branching on channel-specific flags.
 - Channel-oriented addressing: channel-bound address mode with host configured channel base address allows the same function to operate independently on different channels.
 - Channel-bound data address space of up to 128 32-bit parameters (512 bytes).
 - Global parameter address mode allows access to common channel data of up to 256 32-bit parameters (1024 bytes).
 - Support for indirect and stacked data access schemes.
 - Parallel execution of: data access, ALU, channel control and flow control subinstructions in selected combinations.
 - 24-bit registers and ALU, plus one 32-bit register for full-width SDM access.
 - Additional 24-bit multiply/MAC/divide unit which supports all signed/unsigned/multiply/MAC combinations, and unsigned 24-bit divide. The MAC/divide unit works in parallel with the regular microcode commands.

- Resource sharing features resolve channel contention for common use of channel registers, memory and microengine time
 - Hardware scheduler works as a ‘task management’ unit, dispatching event service routines by predefined, host-configured priority.
 - Hardware breakpoints on data access, qualified by address and/or data values.
 - Hardware breakpoints on instruction address.
 - Automatic channel context switch when a ‘task switch’ occurs; that is, one function thread ends and another begins to service a request from another channel. Channel-specific registers, flags and parameter base address are automatically loaded for the next serviced channel.
 - Individual channel priority setting in three levels: high, middle, and low.
 - Scheduler priority scheme allows calculation of worst case latency for event servicing and ensures servicing of all channels by preventing permanent blockage.
 - SDM shared between host core and both eTPU engines, supporting channel-channel or host-channel communication.
 - Hardware implementation of four semaphores allows for resource arbitration between channels in both eTPU engines.
 - Hardware semaphores are directly supported by the microengine instruction set.
 - Dual-parameter coherency hardware support allows coherent (to host) access to 2 parameters by microengines in back-to-back accesses.
 - Coherent dual-parameter controller allows coherent (to microengines) accesses to two parameters by the host.
- Test and development support features
 - Nexus level 3 debug support through the eTPU Nexus block (NDEDI)
 - Software breakpoints
 - SCM (code memory) continuous signature-check built-in code integrity test multiple input signature calculator (MISC): runs concurrently with eTPU normal operation

17.2 Modes of Operation

The eTPU is capable of working in the following modes.

17.2.1 User Configuration Mode

By having access to the shared code memory (SCM), the core has the ability to program the eTPU cores with time functions.

17.2.2 User Mode

In user mode the core does not access the eTPU shared code memory, and pre-defined eTPU functions are used.

17.2.3 Debug Mode

The core debugs eTPU code, accessing special trace/debug features via Nexus interface:

- Hardware breakpoint/watchpoint setting
- Access to internal registers
- Single-step execution
- Forced instruction execution
- Software breakpoint insertion and removal

17.2.4 Module Disable Mode

eTPU engine clocks are stopped through a register write to ETPU_ECR bit MDIS, saving power. Input sampling stops. eTPU engines can be in stop mode independently. Module disable mode stops only the engine clock, so that the shared BIU and global channel registers can be accessed, and interrupts and DMA requests can be cleared and enabled/disabled. An engine only enters module disable mode when any currently running thread is finished.

These modes are loosely selected: there is no unique register field or signals to choose between them. Some features of one mode can be used with features of other modes.

17.2.5 eTPU Mode Selection

User and user configuration are the production operating modes, and differ from each other only in access to SCM.

Module disable mode is entered by setting ETPU_ECR[MDIS]. eTPU engines can be individually stopped (there is one ETPU_ECR for each engine).

17.3 External Signal Description

17.3.1 Overview

There are 65 external signals in each eTPU engine:

- 32 channel input signals,
- 32 channel output signals,
- TCRCLK clock input,

There are a total of 65 external signals in a single-engine system, or 130 external signals in a dual-engine system. There are four internal output disable signals for each eTPU engine that implement the output disable feature needed for motor control.

Refer to [16.2.1.1, “Output Disable Input—eMIOS Output Disable Input Signals,”](#) for more information.

17.3.2 Output and Input Channel Signals

Each eTPU channel has an input and output associated with it, and these can be connected to external pins or wired internally to other peripheral devices. As shown in [Chapter 19, “Deserial Serial Peripheral](#)

Interface (DSPI),” Figure 19-22 and Table 19-20, eTPU output channel 0 (ETPUA[0]_ETPUA[12]_GPIO[114]) is serialized to DSPI C and then connected to input 2 on IMUX for external $\overline{\text{IRQ}}[3]$. Most eTPU channels are serialized, but eTPU channels 22 and 23 are connected only to their pin.

Some channels are serialized through one DSPI to two different locations. The eTPU channel 29 (ETPUA[29]_PCSC[2]_GPIO[143]) is serialized to both eTPU_A input channel 29 and input 1 on IMUX for external $\overline{\text{IRQ}}[8]$. This serialization is performed by DSPI B. Finally, some channels are serialized through different DSPIs. The eTPU channel 17 is serialized through DSPI B to input 1 on IMUX for external $\overline{\text{IRQ}}[6]$, but is also serialized by DSPI D to input 3 on IMUX for external $\overline{\text{IRQ}}[2]$.

Figure 19-21, Figure 19-22, and Figure 19-23 along with Table 19-19, Table 19-20, and Table 19-21 explain the serial connectivities of the eTPU and eMIOS channels.

Table 17-1. eTPU A Channel Connection Table

eTPU_A Channels	eTPU Input/Output Signals	DSPI Inputs ¹	DSPI Outputs	Signals muxed with ETPUA		Pin Assignment
0–9	ETPUA[0:9] Input/Output	DSPI C[4:13]	None	ETPUA[0:9]_ ETPUA[12:21]_ GPIO[114:123]	EMIOS[0:9]_ ETPUA[0:9]_ GPIO[179:188]	Primary Alternate General-purpose I/O
10–11	ETPUA[10:11] Input/Output	DSPI C[14:15]	None	ETPUA[10:11]_ ETPUA[21:23]_ GPIO[124:125]		Primary Alternate General-purpose I/O
12–15	ETPUA[12:15] Input/Output	DSPI C[0:3]	None	ETPUA[12:15]_ PCSB[1, 3:5]_ GPIO[126:129]	ETPUA[0:3]_ ETPUA[12:15]_ GPIO[114:117]	Primary Alternate General-purpose I/O
16–19	ETPUA[16:19] Input/Output	DSPI B[7:4] DSPI D[5:2]	None	ETPUA[16:19]_ PCSD[1:4]_ GPIO[130:133]	ETPUA[4:7]_ ETPUA[16:19]_ GPIO[118:121]	Primary Alternate General-purpose I/O
20–21	ETPUA[20:21] Input/Output	DSPI B[3:2] DSPI D[1:0]	None	ETPUA[20:21]_ IRQ[8:9]_ GPIO[134:135]	ETPUA[8:9]_ ETPUA[20:21]_ GPIO[122:123]	Primary Alternate General-purpose I/O
22–23	ETPUA[22:23] Input/Output	None	None	ETPUA[22:23]_ IRQ[10:11]_ GPIO[136:137]	ETPUA[10:11]_ ETPUA[22:23]_ GPIO[124:125]	Primary Alternate General-purpose I/O
24–27	ETPUA[24:27] Input/Output	DSPI B[13:10] DSPI D[15:12]	DSPI B[13:10]	ETPUA[24:27]_ IRQ[12:15]_ GPIO[138:141]		Primary Alternate General-purpose I/O
28–29	ETPUA[28:29] Input/Output	DSPI B[9:8] DSPI D[11:10]	DSPI B[9:8]	ETPUA[28:29]_ PCSC[1:2]_ GPIO[142:143]		Primary Alternate General-purpose I/O
30–31	ETPUA[30:31] Input/Output	None	None	ETPUA[30:31]_ PCSC[3:4]_ GPIO[144:145]		Primary Alternate General-purpose I/O

¹ The channel numbers for some of the DSPI channels connections are reversed, for example if eTPU A[16:19] is mapped to DSPI B[7:4], then eTPU A[16] is connected to DSPI B[7], eTPU A[17] is connected to DSPI B[6],..., and eTPU A[19] is connected to DSPI B[4]

17.3.2.1 Time Base Clock Signal (TCRCLK[A])

The TCRCLK[A] input signals are used to control the TCR1 and TCR2 time bases for eTPU A.

NOTE

Throughout this document, TCRCLKA is referred to generically as TCRCLK.

There is one independent TCRCLK input for each engine. [Table 17-2](#) shows the TCRCLK pin connections. For pulse accumulator operations TCRCLK can be used as a gate for a counter based on the system clock divided by eight. For angle operations TCRCLK can be used to get the tooth transition indications in angle mode. Refer to the *eTPU Reference Manual's* Sections 5.9 and 5.10.

Table 17-2. MPC5565 TCRCLK Signal

Signal Name	Pin Assignment	I/O	Pin Connection	
			496 BGA	324 BGA
TCRCLKA_ TRQ[7]_ GPIO[113]	Primary Alternate General-purpose I/O	I I I/O	M2	M2

17.3.2.2 Channel Output Disable Signals

Each eTPU engine has four input signals that are used to force the outputs of a group of 8 channels to an inactive level. These signals originate from the eMIOS. When an output disable signal is active, all the eight channels assigned to the disable signal that have their ODIS bits set to one in ETPU_CnCR register have their outputs forced to the opposite of the value specified in the ETPU_CnCR[OPOL] bit. Therefore, individual channels can be selected to be affected by the output disable signals, as well as their disabling forced polarity.

Refer to [Section 16.2.1.1, “Output Disable Input—eMIOS Output Disable Input Signals,”](#) for more information on the output disable signals.

The output disable channel groups are defined in [Table 17-3](#).

Table 17-3. Output Disable Channel Groups

eMIOS Channel	Engine	eTPU Channels Disabled
11	A	0–7
10		8–15
9		16–23
8		24–31

17.4 Memory Map and Register Definition

17.4.1 eTPU Memory Map Overview

The eTPU system simplified memory map is shown in [Table 17-4](#). The base address for the eTPU module is listed as BASE. Each of the register areas shown can have their own reserved address areas.

Table 17-4. eTPU High-Level Memory Map

Address	Register Description
Base (C3FC_0000) – Base + 0x0000_001F	eTPU system module configuration registers
Base + 0x0000_0020– Base + 0x0000_002F	eTPU A time base registers
Base + 0x0000_0030– Base + 0x0000_01FF	Reserved
Base + 0x0000_0200– Base + 0x0000_02FF	eTPU A global channel registers
Base + 0x0000_0300– Base + 0x0000_03FF	Reserved
Base + 0x0000_0400– Base + 0x0000_07FF	eTPU A channel registers
Base + 0x0000_0800– Base + 0x0000_7FFF	Reserved
Base + 0x0000_8000– Base + 0x0000_89FF	Shared data memory (2.5 KB)
Base + 0x0000_8A00– Base + 0x0000_BFFF	Reserved
Base + 0x0000_C000– Base + 0x0000_C9FF	Shared data memory PSE mirror ¹ (2.5 KB)
Base + 0x0000_CA00– Base + 0x0000_FFFF	Reserved
Base + 0x0001_0000– Base + 0x0001_2FFF	Shared code memory (12 KB)
Base + 0x0001_3000– Base + 0x0001_FFFF	Not writable Reads the return value of ETPU_SCMOFFDATAR register.

¹ Parameter Sign Extension access area. Refer to the *eTPU Reference Manual*.

17.4.2 eTPU Register Addresses

Table 17-5 shows the eTPU registers and their locations, without examples or explanation of how the fields are used. For a complete description of these registers, refer to the *Enhanced Time Processing Unit (eTPU) Reference Manual*. The features are explained in detail there.

Table 17-5. Detailed Memory Map

Address	Register Name	Register Description	Bits
Base = 0xC3FC_0000	ETPU_MCR	eTPU module configuration register	32
Base + 0x0000_0004	ETPU_CDCR	eTPU coherent dual-parameter controller register	32
Base + 0x0000_0008	—	Reserved	—
Base + 0x0000_000C	ETPU_MISCCMPR	eTPU MISC compare register	32

Base + 0x0001_3000– Base + 0x0001_FFFF	—	Reserved	—

¹ Parameter sign extension access area. Refer to the *eTPU Reference Manual*.

² SCM access is only available under certain conditions when ETPU_MCR[VIS] = 1. The SCM can only be written in 32-bit accesses.

17.4.3 System Configuration Registers

17.4.3.1 eTPU Module Configuration Register (ETPU_MCR)

This register is global to both eTPU engines, and resides in the shared BIU. ETPU_MCR gathers global configuration and status in the eTPU system, including global exception. It is also used for configuring the SCM (shared code memory) operation and test.

Address: Base + 0x0000_0000

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 17-5. eTPU Module Configuration Register (ETPU_MCR)
Table 17-6. ETPU_MCR Field Descriptions

Field	Description
0 GEC	Global exception clear. Negates global exception request and clears global exception status bits MGEA, MGEB, ILFA, ILFB and SCMMISF. A read always returns 0. Writes have the following effect: 0 Keep global exception request and status bits ILFA, ILFB, MGEA, MGEB, and SCMMISF as is. 1 Negate global exception, clear status bits ILFA, ILFB, MGEA, MGEB, and SCMMISF. GEC works the same way with either one or both engines in stop mode.
1–3	Reserved.

Table 17-6. ETPU_MCR Field Descriptions (continued)

Field	Description
4 MGEA	Microcode global exception engine A. Indicates that a global exception was asserted by microcode executed on the respective engine. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0 No microcode-requested global exception pending. 1 Global exception requested by microcode is pending.
5 MGEB	Microcode global exception engine B. Indicates that a global exception was asserted by microcode executed on the respective engine. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0 No microcode requested global exception pending. 1 Global exception requested by microcode is pending.
6 ILFA	Illegal instruction flag eTPU A. Set by the microengine to indicate that an illegal instruction was decoded in engine A. This bit is cleared by host writing 1 to GEC. For more information about illegal instructions, refer to Section 9.6 in the <i>eTPU Reference Manual</i> . 0 Illegal Instruction not detected. 1 Illegal Instruction detected by eTPU A.
7–10	Reserved.
11–15 SCMSIZE [0:4]	SCM size. Holds the number of 2 KB SCM Blocks minus 1. This value is MCU-dependent.
16–20	Reserved.
21 SCMMISF	SCM MISC Flag. Set by the SCM MISC (multiple input signature calculator) logic to indicate that the calculated signature does not match the expected value, at the end of a MISC iteration. For more details, refer to the <i>eTPU Reference Manual</i> for more details. 0 Signature mismatch not detected. 1 MISC has read entire SCM array and the expected signature in ETPU_MISCCMPR does not match the value calculated. This bit is cleared by writing 1 to GEC.
22 SCM MISEN	SCM MISC enable. Used for enabling/disabling the operation of the MISC logic. SCMMISEN is readable and writable at any time. The MISC logic only operates when this bit is set to 1. When the bit is reset the MISC address counter is set to the initial SCM address. When enabled, the MISC continuously cycles through the SCM addresses, reading each and calculating a CRC. To save power, the MISC can be disabled by clearing the SCMMISEN bit. For more details, refer to the <i>eTPU Reference Manual</i> . 0 MISC operation disabled. The MISC logic is reset to its initial state. 1 MISC operation enabled. (Toggling to 1 clears the SCMMISF bit) SCMMISEN is cleared automatically when MISC logic detects an error; that is, when SCMMISF transitions from 0 to 1, disabling the MISC operation.
23–24	Reserved.
25 VIS	SCM visibility. Determines SCM visibility to the slave bus interface and resets the MISC state (but SCMMISEN keeps its value). 0 SCM is not visible to the slave bus. Accessing SCM address space issues a bus error. 1 SCM is visible to the slave bus. The MISC state is reset. This bit is write protected when any of the engines are not in halt or stop states. When VIS=1, the ETPU_ECR MDIS bits are write protected, and only 32-bit aligned SCM writes are supported. The value written to SCM is unpredictable if other transfer sizes are used.

Table 17-6. ETPU_MCR Field Descriptions (continued)

Field	Description
26 – 30	Reserved.
31 GTBE	Global time base enable. Enables time bases in both engines, allowing them to be started synchronously. An assertion of GTBE also starts the eMIOS time base ¹ . This enables the eTPU time bases and the eMIOS time base to all start synchronously. 1 time bases in both eTPU engines and eMIOS are enabled to run. 0 time bases in both engines are disabled to run. Note: When GTBE is turned off with Angle Mode enabled, the EAC must be reinitialized before GTBE is turned on again.

¹ The eMIOS also has a GTBE bit. Assertion of either the eMIOS or eTPU GTBE bit starts time bases for the eMIOS and eTPU, refer to the *eTPU Reference Manual*.

17.4.3.2 eTPU Coherent Dual-Parameter Controller Register (ETPU_CDCR)

ETPU_CDCR configures and controls dual-parameter coherent transfers. For more information, refer to the *eTPU Reference Manual*.

Address: Base + 0x0000_0004

Access: R/W

Figure 17-6. eTPU Coherent Dual-Parameter Controller Register (ETPU_CDCR)
Table 17-7. ETPU_CDCR Field Descriptions

Field	Description
0 STS	Start. Set by the host to start the data transfer between the parameter buffer pointed by PBBASE and the target addresses selected by the concatenation of fields CTBASE and PARM0/1. The host receives wait-states until the data transfer is complete. Coherency logic resets STS after the data transfer is complete. For more information, refer to the <i>eTPU Reference Manual</i> . 0 (Write) does not start a coherent transfer. 1 (Write) starts a coherent transfer.
1–5 CTBASE [0:4]	Channel transfer base. This field concatenates with fields PARM0/PARM1 to determine the absolute offset (from the SDM base) of the parameters to be transferred: Parameter 0 address = {CTBASE, PARM0} × 4 + SDM base Parameter 1 address = {CTBASE, PARM1} × 4 + SDM base

Table 17-7. ETPU_CDCR Field Descriptions (continued)

Field	Description
6–15 PBBASE [0:9]	Parameter buffer base address. Points to the base address of the parameter buffer location, with granularity of 2 parameters (8 bytes). The host (byte) address of the first parameter in the buffer is PBBASE × 8 + SDM Base Address.
16 PWIDTH	Parameter width selection. Selects the width of the parameters to be transferred between the PB and the target address. 0 Transfer 24-bit parameters. The upper byte remains unchanged in the destination address. 1 Transfer 32-bit parameters. All 32 bits of the parameters are written in the destination address.
17–23 PARM0 [0:6]	Channel parameter number 0. This field in concatenation with CTBASE[3:0] determine the address offset (from the SDM base address) of the parameter which is the destination or source (defined by WR) of the coherent transfer. The SDM address offset of the parameter is {CTBASE, PARM0}*4. PARM0 allows non-contiguous parameters to be transferred coherently ¹ .
24 WR	Read/Write selection. This bit selects the direction of the coherent data transfer. 0 Read operation. Data transfer is from the selected parameter RAM address to the PB. 1 Write operation. Data transfer is from the PB to the selected parameter RAM address.
25–31 PARM1 [0:6]	Channel parameter number 1. This field in concatenation with CTBASE[3:0] determines the address offset (from the SDM base) of the parameter which is the destination or source (defined by WR) of the coherent transfer. The SDM address offset of the parameter is {CTBASE, PARM1}*4. PARM1 allows non-contiguous parameters to be transferred coherently ¹ .

¹ The parameter pointed by {CTBASE, PARM0} is the first transferred.

17.4.3.3 eTPU MISC Compare Register (ETPU_MISCCMPR)

The multiple input signature calculator compare register (ETPU_MISCCMPR) holds the 32-bit signature expected from the whole shared code memory (SCM) array. This register must be written by the host with the 32-bit word to be compared against the calculated signature at the end of the MISC cycle. This register is global to both eTPU engines. For more details, refer to the *eTPU Reference Manual*.

Address: Base + 0x0000_000C

Access: R/W

Figure 17-7. eTPU MISC Compare Register (ETPU_MISCCMPR)

Table 17-8. ETPU_MISCCMPR Field Descriptions

Field	Description
0–31 EMISCCMP [0:31]	Expected multiple input signature calculator compare register value. For more information, refer to the <i>eTPU Reference Manual</i> .

17.4.3.4 eTPU SCM Off-Range Data Register (ETPU_SCMOFFDATAR)

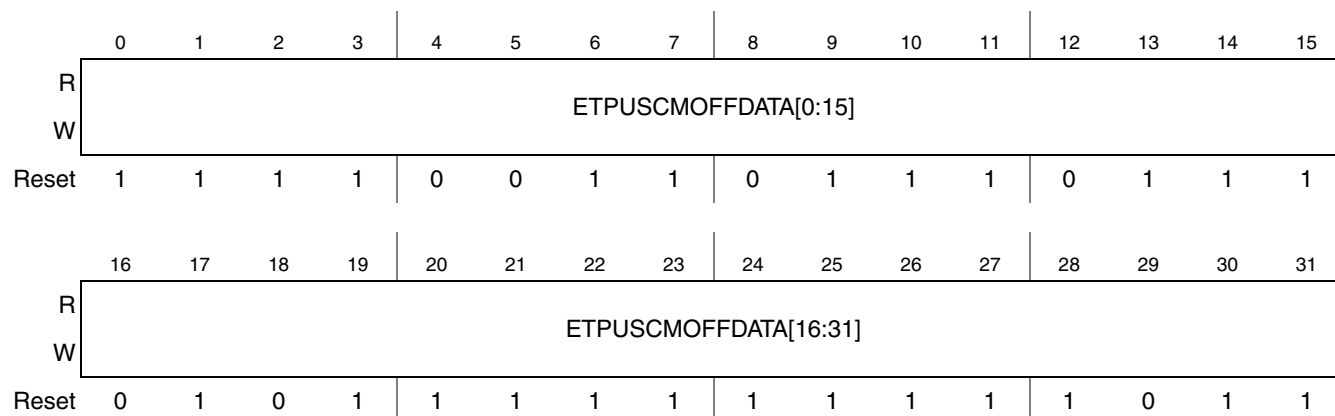

ETPU_SCMOFFDATAR holds the 32-bit value returned when the SCM array is accessed at non implemented addresses, either by the host or by the microengine. This register can be written by the host with the 32-bit instruction to be executed by the microengine to recover from runaway code. This register is global to both ETPU engines.

NOTE

The ETPU_SCMOFFDATAR reset value is the opcode of an instruction that disables matches, clears the TDLs and the MRLs; the opcode also issues an illegal instruction Global Exception, and ends the thread.

Address: Base + 0x0000_0010

Access: R/W

Table 17-9. ETPU_SCMOFFDATAR Field Descriptions

Field	Description
0–31 ETPU SCMOFF DATAR	SCM Off-range read data value.

17.4.3.5 eTPU Engine Configuration Register (ETPU_ECR)

Each engine has its own ETPU_ECR. The ETPU_ECR holds configuration and status fields that are programmed independently in each engine.

Enhanced Time Processing Unit (eTPU)

Address: Base + 0x0000_0014 (eTPU A)

Access: R/W

Figure 17-9. eTPU Engine Configuration Register (ETPU_ECR)

Table 17-10. ETPU_ECR Field Descriptions

Field	Description
0 FEND	Force end. Assertion terminates any current running thread as if an END instruction have been executed. For more information, refer to the <i>eTPU Reference Manual</i> . 0 Normal operation. 1 Terminates current thread. This bit is self-negating.
1 MDIS	Module disable internal stop. This is the low power stop bit. When MDIS is set, the engine shuts down its internal clocks. TCR1 and TCR2 cease to increment, and input sampling stops. The engine asserts the stop flag (STF) bit to indicate that it has stopped. However, the BIU continues to run, and the host can access all registers except for the channel registers ¹ and writes to time base registers. For more information on channel registers, refer to Section 17.4.6, “Channel Configuration and Control Registers.” After MDIS is set, even before STF asserts, data read from the channel registers is not meaningful, a Bus Error is issued, and writes are unpredictable. When the MDIS bit is asserted while the microcode is executing, the eTPU stops when the thread is complete. 0 eTPU engine runs. 1 Commands engine to stop its clocks. Stop completes on the next system clock after the stop condition is valid. The MDIS bit is write-protected when ETPU_MCR[VIS]=1. Note: After the MDIS has been switched from 1 to 0 or vice-versa, do not switch its value again until STF is switched to the same value.
2	Reserved.
3 STF	Stop flag bit. Each engine asserts its stop flag (STF) to indicate that it has stopped. Only then the host can assume that the engine has actually stopped. The eTPU system is fully stopped when the STF bits of both eTPU engines are asserted. The engine only stops when any ongoing thread is complete in this case. 0 The engine is operating. 1 The engine has stopped (after the local MDIS bit has been asserted). Summarizing engine stop conditions, which STF reflects: STF_A:= (after stop completed) MDIS_A STF_B:= (after stop completed) MDIS_B STF_A and STF_B mean STF bit from engine A and STF bit from engine B respectively.
4–7	Reserved.

Table 17-10. ETPU_ECR Field Descriptions (continued)

Field	Description																		
8 HLTF	Halt mode flag. If eTPU engine entered halt state, this flag is asserted. The flag remains asserted while the microengine is in halt state, even during a single-step or forced instruction execution. Refer to the <i>eTPU Reference Manual</i> for further details about entering halt mode. 0 eTPU engine is not halted. 1 eTPU engine is halted																		
9–12	Reserved.																		
13–15 FPSCK [0:2]	<p>Filter prescaler clock control. Controls the prescaling of the clocks used in digital filters for the channel input signals and TCRCLK input. The following table illustrates filter prescaler clock control.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>Filter Control</th> <th>Sample on System Clock Divided by:</th> </tr> </thead> <tbody> <tr><td>000</td><td>2</td></tr> <tr><td>001</td><td>4</td></tr> <tr><td>010</td><td>8</td></tr> <tr><td>011</td><td>16</td></tr> <tr><td>100</td><td>32</td></tr> <tr><td>101</td><td>64</td></tr> <tr><td>110</td><td>128</td></tr> <tr><td>111</td><td>256</td></tr> </tbody> </table> <p>Filtering can be controlled independently by the engine, but all input digital filters in the same engine have same clock prescaling. ¹ The time base registers can still be read in stop mode, but writes are ineffective and a bus error is issued. Global channel registers and SDM can be accessed normally.

17.4.4 Time Base Registers

Time base registers allow the configuration and visibility of internally-generated time bases TCR1 and TCR2. There is one of each of these registers for each eTPU engine.

NOTE

Writes to this register generate a bus error and are ineffective when MDIS = 1. Reads are always permitted.

17.4.4.1 eTPU Time Base Configuration Register (ETPU_TBCCR)

This register configures several time base options.

Address: Base + 0x0000_0020 (eTPU A)

Access: R/W

Figure 17-10. eTPU Time Base Configuration Register (ETPU_TBCCR)

Table 17-11. ETPU_TBCR Field Descriptions

Field	Description																											
0–2 TCR2CTL	<p>TCR2 clock and gate control are part of the TCR2 clocking system. These bits determine the clock source for TCR2 before the prescaler. TCR2 can count on any detected edge of the TCRCLK signal or use it for gating the system clock divided by 8. After reset, the TCRCLK signal rising edge is selected. TCR2 can also be clocked by the system clock divided by 8. TCR2CTL also determines the TCRCLK edge selected for angle tooth detection in angle mode. Refer to the <i>eTPU Reference Manual</i> for more information. TCR2 clock sources are listed in the following table.</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">TCR2CTL</th> <th style="text-align: center;">AM = 0 (TCR2 Clock)</th> <th style="text-align: center;">AM = 1 (Angle Tooth Detection)</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">000</td> <td>Gated DIV8 clock (system clock / 8). 3–4 TCRCF	<p>TCRCLK signal filter control. Controls the TCRCLK digital filter determining whether the TCRCLK signal input (after a synchronizer) is filtered with the same filter clock as the channel input signals or uses the system clock divided by 2, and also whether the TCRCLK digital filter works in integrator mode or two sample mode. The following table describes TCRCLK filter clock/mode.</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">TCRCF</th> <th style="text-align: center;">Filter Input</th> <th style="text-align: center;">Filter Mode</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">00</td> <td>System clock divided by 2</td> <td>two sample</td> </tr> <tr> <td style="text-align: center;">01</td> <td>Filter clock of the channels</td> <td>two sample</td> </tr> <tr> <td style="text-align: center;">10</td> <td>System clock divided by 2</td> <td>integration</td> </tr> <tr> <td style="text-align: center;">11</td> <td>Filter clock of the channels</td> <td>integration</td> </tr> </tbody> </table> <p>For more information, refer to the <i>eTPU Reference Manual</i>.</p>	TCRCF	Filter Input	Filter Mode	00	System clock divided by 2	two sample	01	Filter clock of the channels	two sample	10	System clock divided by 2	integration	11	Filter clock of the channels	integration												
TCRCF	Filter Input	Filter Mode																										
00	System clock divided by 2	two sample																										
01	Filter clock of the channels	two sample																										
10	System clock divided by 2	integration																										
11	Filter clock of the channels	integration																										

Table 17-11. ETPU_TBCR Field Descriptions (continued)

Field	Description										
5	Reserved.										
6 AM	<p>Angle mode selection. When the AM bit is set, the EAC (eTPU Angle Clock) hardware provides angle information to the channels using the TCR2 bus. When the AM bit is cleared (non-angle mode), EAC operation is disabled, and its internal registers can be used as general purpose registers.</p> <p>0 EAC operation is disabled. 1 TCR2 works in angle mode;</p> <p>Note: AM must not be changed when ETPU_MCR[GTBE] = 1. Note: Changing AM can cause expurious transition detections on channel 0, depending on the channel mode and state. For more information, refer to the <i>eTPU Reference Manual</i>.</p>										
7–9	Reserved.										
10–15 TCR2P	<p>Timer count register 2 prescaler control. Part of the TCR2 clocking system. TCR2 is clocked from the output of a prescaler. The prescaler divides its input by (TCR2P+1) allowing frequency divisions from 1 to 64. The prescaler input is the system clock divided by 8 (in gated or non-gated clock mode) or Internal Timebase input, or TCRCLK filtered input. This field has no effect on TCCR2 in Angle Mode. For more information on TCR2, refer to the <i>eTPU Reference Manual</i>.</p>										
16–23 TCR1CTL	<p>TCR1 clock/gate control. Part of the TCR1 clocking system. It determines the clock source for TCR1. TCR1 can count on detected rising edge of the TCRCLK signal or the system clock divided by 2. After reset TCRCLK signal is selected. The following table shows the selection of the TCR1 clock source.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>TCR1CTL</th> <th>TCR1 Clock</th> </tr> </thead> <tbody> <tr> <td>00</td> <td>selects TCRCLK as clock source for the TCR1 prescaler (must not be use in Angle Mode)</td> </tr> <tr> <td>01</td> <td>Reserved</td> </tr> <tr> <td>10</td> <td>selects system clock divided by 2 as clock source for the TCR1 prescaler</td> </tr> <tr> <td>11</td> <td>TCR1CTL shuts down TCR1 clock. TCR1 can still change if STAC client.</td> </tr> </tbody> </table> <p>For more information on the TCR1 clocking system, refer to the <i>eTPU Reference Manual</i>.</p>	TCR1CTL	TCR1 Clock	00	selects TCRCLK as clock source for the TCR1 prescaler (must not be use in Angle Mode)	01	Reserved	10	selects system clock divided by 2 as clock source for the TCR1 prescaler	11	TCR1CTL shuts down TCR1 clock. TCR1 can still change if STAC client.
TCR1CTL	TCR1 Clock										
00	selects TCRCLK as clock source for the TCR1 prescaler (must not be use in Angle Mode)										
01	Reserved										
10	selects system clock divided by 2 as clock source for the TCR1 prescaler										
11	TCR1CTL shuts down TCR1 clock. TCR1 can still change if STAC client.										
24–31 TCR1P	<p>Timer count register 1 prescaler control. Clocked from the output of a prescaler. The input to the prescaler is the internal eTPU system clock divided by 2 or the output of TCRCLK filter, or Peripheral Timebase input. The prescaler divides this input by (TCR1P+1) allowing frequency divisions from 1 up to 256.</p>										

17.4.4.2 eTPU Time Base 1 (TCR1) Visibility Register (ETPU_TB1R)

This register provides visibility of the TCR1 time base for core host read access. This register is read-only. The value of the TCR1 time base shown can be driven by the TCR1 counter or imported, depending on the configuration set in ETPU_REDCR. For more information, refer to the *eTPU Reference Manual*.

Address: Base + 0x0000_0024 (eTPU A)

Access: R/O

Figure 17-11. eTPU Time Base 1 (TCR1) Visibility Register (ETPU_TB1R)

Table 17-12. ETPU_TB1R Field Descriptions

Field	Description
0–7	Reserved.
8–31 TCR1 [0:23]	TCR1 value. Used on matches and captures. For more information, refer to the <i>eTPU Reference Manual</i> .

17.4.4.3 eTPU Time Base 2 (TCR2) Visibility Register (ETPU_TB2R)

This register provides visibility of the TCR2 time base for core host read access. This register is read-only. The value of the TCR2 time base shown can be driven by the TCR2 counter, the angle mode logic, or imported from the STAC interface, depending on angle mode (an engine cannot import when in angle mode) and STAC interface configurations set in registers ETPU_TBCR and ETPU_REDCR. For more information on time bases, refer to the *eTPU Reference Manual*.

Address: Base + 0x0000_0028 (eTPU A)

Access: R/O

Figure 17-12. eTPU Time Base 2 (TCR2) Visibility Register (ETPU_TB2R)

Table 17-13. ETPU_TB2R Bit Field Descriptions

Field	Description
0–7	Reserved.
8–31 TCR2 [0:23]	TCR2 value. Used on matches and captures. For information on TCR2, refer to the <i>eTPU Reference Manual</i> .

17.4.4.4 STAC Bus Configuration Register (ETPU_REDCR)

This register configures the eTPU STAC bus interface module and operation. For more information on the STAC interface, refer to the *eTPU Reference Manual*.

Address: Base + 0x0000_002C (eTPU A)

Access: R/W

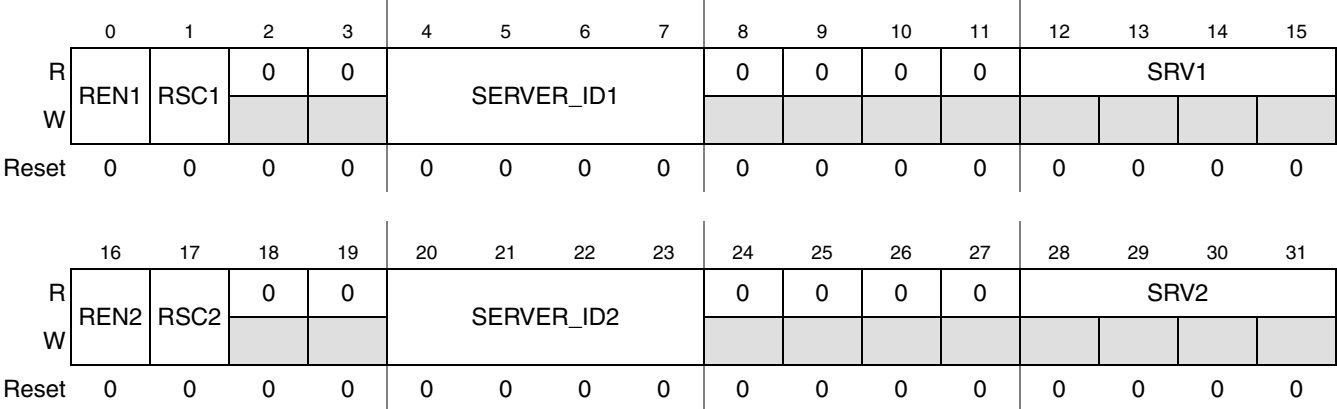

Figure 17-13. STAC Bus Configuration Register (ETPU_REDCR)

Table 17-14. ETPU_REDCR Field Descriptions

Field	Description
0 REN1	TCR1 resource ¹ client/server operation enable. Enables or disables client/server operation for the eTPU STAC interface. REN1 enables TCR1. 0 Server/client operation for resource 1 is disabled. 1 Server/client operation for resource 1 is enabled.
1 RSC1	TCR1 resource server/client assignment. Selects the eTPU data resource assignment to be used as a server or client. RSC1 selects the functionality of TCR1. For server mode, external plugging determines the unique server address assigned to each TCR. For a client mode, the SRV1 field determines the server address to which the client listens. 0 Resource client operation. 1 Resource server operation.
2–3	Reserved.
4–7 SERVER_ID1	STAC bus address for TCR1 as a server. For more information on the STAC interface, refer to the <i>eTPU Reference Manual</i> .
8–11	Reserved.
12–15 SRV1 [0:3]	TCR1 resource server. Selects the address of the specific STAC Server the local TCR1 listens to when configured as a STAC client. For more information on the STAC interface, refer to the <i>eTPU Reference Manual</i> .
16 REN2	TCR2 resource ¹ client/server operation enable. Enables or disables client/server operation for eTPU slave resources. REN2 enables TCR2 slave bus operations. 1 Server/client operation for resource 2 is enabled. 0 Server/client operation for resource 2 is disabled.

Table 17-14. ETPU_REDCR Field Descriptions (continued)

Field	Description
17 RSC2	TCR2 ² resource server/client assignment. Selects the eTPU data resource assignment to be used as a server or client. RSC2 selects the functionality of TCR2. For server mode, external plugging determines the unique server address assigned to each TCR. For a client mode, the SRV2 field determines the Server address to which the client listens. 0 Resource Client operation. 1 Resource Server operation.
18–19	Reserved.
20–23 SERVER_ID2	STAC bus address for TCR2 as a server.
24–27	Reserved.
28–31 SRV2 [0:3]	TCR2 resource server. Selects the address of the specific STAC server the local TCR2 listens to when configured as a STAC Client. For more information on the STAC interface, refer to the <i>eTPU Reference Manual</i> .

¹ Resource identifies any parameter that changes in time and can be exported / imported from other device. For the eTPU, a resource can be TCR1 or TCR2 (either time or angle values).

² When TCR2 is configured as a STAC bus client (REN2 = 1, RSC2 = 0) the angle clock hardware must be disabled (ETPU_TBCR[AM] = 0).

17.4.5 Global Channel Registers

The registers in this section group, by type, the interrupt status and enable bits from all the channels. This organization eases management of all channels or groups of channels by a single interrupt handler routine. These bits are mirrored by the individual channel registers.

17.4.5.1 eTPU Channel Interrupt Status Register (ETPU_CISR)

Host interrupt status from all channels are grouped in ETPU_CISR. The bits are mirrored by the channels' status/control registers. For more information, refer to [Section 17.4.6.3, “eTPU Channel n Status Control Register \(ETPU_CnSCR\),”](#) and the *eTPU Reference Manual*.

NOTE

The host core must write 1 to clear (w1c) an interrupt status bit.

Field	Description
0–31 CISn	Channel <i>n</i> interrupt status. 0 indicates that channel <i>n</i> has no pending interrupt to the host core. 1 indicates that channel <i>n</i> has a pending interrupt to the host core. To clear a status bit, the host must write 1 to it. For details about interrupts refer to the <i>eTPU Reference Manual</i> .

17.4.5.2 eTPU Channel Data Transfer Request Status Register (ETPU_CDTRSR)

Data transfer request status from all channels are grouped in ETPU_CDTRSR. The bits are mirrored by the channels’ status/control registers. For more information on data transfers and channel control registers, refer to the *eTPU Reference Manual*.

In the MPC5566, eTPU A channels [0:2,12:15,28:29] are connected to the DMA; in the MPC5565, eTPU channels [0:2, 14:15] are DMA connected. The data transfer request lines that are not connected to the DMA controller are left disconnected and do not generate transfer requests, even if their request status bits are asserted in registers ETPU_CDTRSR and ETPU_CnSCR. Channels that are not connected can still have their status bits (DTRSn) cleared by writing a 1 to the appropriate field.

17.4.5.3 eTPU Channel Interrupt Overflow Status Register (ETPU_CIOSR)

An interrupt overflow occurs when an interrupt is issued for a channel when the previous interrupt status bit for the same channel has not been cleared. Interrupt overflow status from all channels are grouped in ETPU_CIOSR. The bits are mirrored by the channels’ status/control registers. For information about channel status registers and overflow, refer to [Section 17.4.6.3, “eTPU Channel *n* Status Control Register \(ETPU_CnSCR\),”](#) and the *eTPU Reference Manual*.

NOTE

The host must write 1 to clear an interrupt overflow status bit.

17.4.5.7 eTPU Channel Pending Service Status Register (ETPU_CPSSR)

ETPU_CPSSR is a read-only register that holds the status of the pending channel service requests. For information on channel service requests, refer to the *eTPU Reference Manual*.

NOTE

More than one source can request service when a channel’s service request bit is set.

Address: Base + 0x0000_0280 (eTPU A)

Access: R/O

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 17-20. eTPU Channel Pending Service Status Register (ETPU_CPSSR)

Table 17-21. ETPU_CPSSR Bit Field Descriptions

Field	Description
0–31 SR n	<p>Pending service request n. Indicates a pending service request for channel n. The SR status for the pending request is negated at the time slot transition for the respective service thread.</p> <p>0 no service request pending for channel n 1 pending service request for channel n</p>

NOTE

The pending service status bit for a channel is set when a service request is pending, even if the Channel is disabled ($CPR_n = 0$).

17.4.5.8 eTPU Channel Service Status Register (ETPU_CSSR)

ETPU_CSSR holds the current channel service status on whether it is being serviced or not. Only one bit can be asserted in this register at a given time. When no channel is being serviced, the register read value is 0x0000_0000. ETPU_CSSR is a read-only register. This register can be read during normal eTPU operation for monitoring the scheduler activity. For more information on channels being serviced, refer to the *eTPU Reference Manual*.

NOTE

The ETPU_CSSR is not an absolute indication of channel status. If more than one source is requesting service, the asserted status bit only indicates that one of the requests has been granted.

NOTE

Channel service status does not always reflect decoding of the CHAN register, since the CHAN register can be changed by the service thread microcode.

Figure 17-21. ETPU_CSSR Register

Table 17-22. ETPU_CSSR Field Descriptions

Field	Description
0–31 SS n	Service status n . Indicates that channel n is currently being serviced. It is updated at the 1st microcycle of a time slot transition. 0 channel n is not currently being serviced 1 channel n is currently being serviced Refer to the <i>eTPU Reference Manual</i> for more information on time slot transitions.

17.4.6 Channel Configuration and Control Registers

Each channel, for both eTPU engines, has a group of three registers used to control, configure and check status of that channel as shown in [Table 17-23](#).

Table 17-23. Channel Registers Structure

Channel Offset	Register Name
0x0000	eTPU channel configuration register (ETPU_CnCR)
0x0004	eTPU channel status/control register ¹ (ETPU_CnSCR)
0x0008	eTPU channel host service request register (ETPU_CnHSRR)
0x000C	Reserved

¹ In the MPC5565, eTPU A channels [0:2, 14:15] are connected. The data transfer request lines that are not connected to the DMA controller are left disconnected and do not generate interrupt requests, even if their request status bits assert in registers ETPU_CDTRSR and ETPU_CnSCR.

17.4.6.1 Channel Registers Layout

One contiguous area is used to map all channel registers of each eTPU engine as shown in [Table 17-24](#).

Table 17-24. eTPU Channel Register Map

Address	Registers Structure
Base + 0x0000_0400	eTPU A channel 0 register structure
Base + 0x0000_0410	eTPU A channel 1 register structure
Base + 0x0000_0420	eTPU A channel 2 register structure
Base + 0x0000_0430– Base + 0x0000_05D0	⋮
Base + 0x0000_05E0	eTPU A channel 30 register structure
Base + 0x0000_05F0	eTPU A channel 31 register structure
Base + 0x0000_0600– Base + 0x0000_07FF	Reserved

There are 64 structures defined, one for each available channel in the eTPU System (32 for each engine). The base address for the structure presented can be calculated by using the following equation:

$$\text{Channel_Register_Structure_Base_Address} = \text{ETPU_Engine_Channel_Base} + (\text{channel_number} \times 0x0000_0010)$$

where:

$$\text{ETPU_Engine_Channel_Base} = \text{ETPU_Base} + 0x0000_0400 = \text{ETPU A}$$

17.4.6.2 eTPU Channel *n* Configuration Register (ETPU_CnCR)

The ETPU_CnCR is a collection of the configuration bits related to an individual channel. Some of these bits are mirrored from the global channel registers.

Address: Channel_Register_Base + 0x0000

Access: R/W

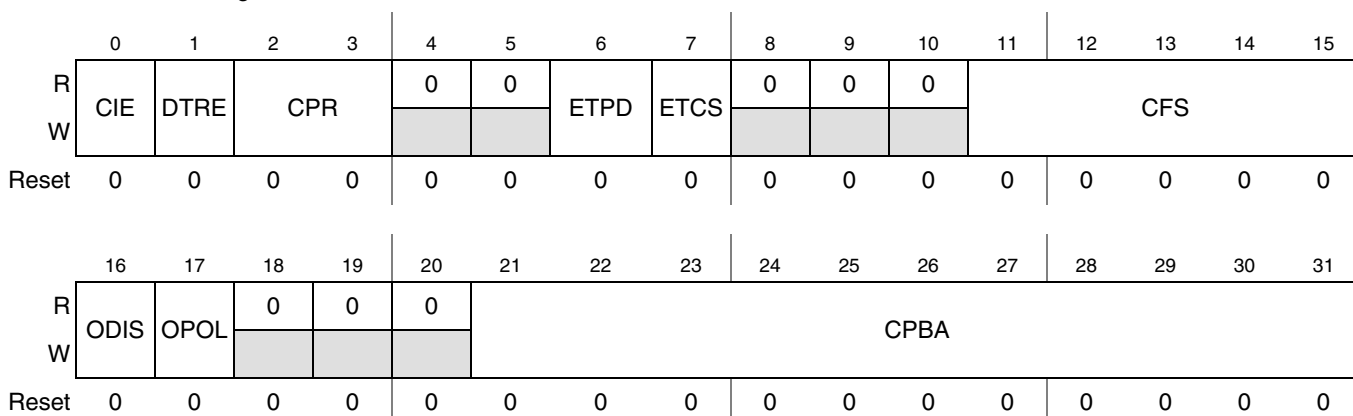

Figure 17-22. ETPU Channel *n* Configuration Register (ETPU_CnCR)

Table 17-25. ETPU_CnCR Field Descriptions

Field	Description										
0 CIE	Channel interrupt enable. This bit is mirrored from the ETPU_CIER 0 Disable interrupt for this channel. For more information, refer to the <i>eTPU Reference Manual</i> . 1 Enable interrupt for this channel.										
1 DTRE	Channel data transfer request enable. This bit is mirrored from the ETPU_CDTRER. 0 Disable data transfer request for this channel. Refer to the <i>eTPU Reference Manual</i> for more information. 1 Enable data transfer request for this channel.										
2–3 CPR [0:1]	Channel priority. Defines the priority level for the channel. The priority level is used by the hardware scheduler. The values for CPR[1:0] and corresponding levels are shown in the table below. <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>CPR</th> <th>Priority</th> </tr> </thead> <tbody> <tr> <td>00</td> <td>Disabled</td> </tr> <tr> <td>01</td> <td>Low</td> </tr> <tr> <td>10</td> <td>Middle</td> </tr> <tr> <td>11</td> <td>High</td> </tr> </tbody> </table> <p>For more information on the hardware scheduler, refer to the <i>eTPU Reference Manual</i>.</p>	CPR	Priority	00	Disabled	01	Low	10	Middle	11	High
CPR	Priority										
00	Disabled										
01	Low										
10	Middle										
11	High										
4–5	Reserved.										
6 ETPD	This bit selects which channel signal, input or output, is used in the entry point selection. The ETPD value has to be compatible with the function chosen for the channel, selected in the field CFS. For details about entry table and condition encoding schemes, refer to the <i>eTPU Reference Manual</i> . The ETPD bit is only present in the MPC5565 and MPC5567. 0 Use PSTI for entry point selection. 1 Use PSTO for entry point selection.										
7 ETCS	Entry table condition select. Determines the channel condition encoding scheme that selects the entry point to be taken in an entry table. The ETCS value has to be compatible with the function chosen for the channel, selected in ETPU_CnCR[CFS]. Two condition encoding schemes are available. 1 Select alternate entry table condition encoding scheme. 0 Select standard entry table condition encoding scheme. For details about entry table and condition encoding schemes, refer to the <i>eTPU Reference Manual</i> .										
8–10	Reserved.										
11–15 CFS [0:4]	Channel function select. Defines the function to be performed by the channel. The function assigned to the channel has to be compatible with the channel condition encoding scheme, selected by ETPU_CnCR[ETCS]. For more information about functions, refer to the <i>eTPU Reference Manual</i> .										
16 ODIS	Output disable. Enables the channel to have its output forced to the value opposite to OPOL when the output disable input signal corresponding to the channel group that it belongs is active. 0 Turns off the output disable feature for the channel. For more information on output disable, refer to the <i>eTPU Reference Manual</i> . 1 Turns on the output disable feature for the channel										
17 OPOL	Output polarity. Determines the output signal polarity. The activation of the output disable signal forces, when enabled by ETPU_CnCR[ODIS], the channel output signal to the opposite of this polarity. 0 Output active low (output disable drives output to high) 1 Output active high (output disable drives output to low)										

Table 17-25. ETPU_CnCR Field Descriptions (continued)

Field	Description
18–20	Reserved.
21–31 CPBA [0:10]	Channel <i>n</i> parameter base address. The value of this field multiplied by 8 specifies the SDM parameter base host (byte) address for channel <i>n</i> (2-parameter granularity). The formula for calculating the absolute channel parameter base (byte) address, as seen by the host, is $eTPU_Base + 0x8000 + CPBA * 8$. The SDM is mirrored in the parameter sign extension (PSE) area. The formula to calculate the absolute channel parameter base (byte) address in the PSE area is $eTPU_Base + 0xC000 + CPBA * 8$. For more information on SDM addresses, refer to the <i>eTPU Reference Manual</i> .

17.4.6.3 eTPU Channel *n* Status Control Register (ETPU_CnSCR)

ETPU_CnSCR is a collection of the interrupt status bits of the channel, and also the function mode definition (read-write). Bits CIS, CIOS, DTRS, and DTROS for each channel can also be accessed from ETPU_CISR, ETPU_CIOSR, ETPU_CDTRSR, and ETPU_CDTROSR respectively. For more information on the three previously mentioned registers, refer to the *eTPU Reference Manual*.

NOTE

The device core must write 1 to clear a status bit.

NOTE

In the MPC5565, eTPU A channels [0:2, 14:15] are DMA connected. The data transfer request lines that are not connected to the DMA controller are left disconnected and do not generate transfer requests, even if their request status bits assert in registers ETPU_CDTRSR and ETPU_CnSCR

Address: Channel_Register_Base + 0x0004

Figure 17-23. eTPU Channel *n* Status Control Register (ETPU_CnSCR)

Table 17-26. ETPU_CnSCR Field Descriptions

Field	Description
0 CIS	Channel interrupt status. 0 Channel has no pending interrupt to the device core. 1 Channel has a pending interrupt to the device core. CIS is mirrored in the ETPU_CISR. For more information on ETPU_CISR and interrupts, refer to Section 17.4.5.1, “eTPU Channel Interrupt Status Register (ETPU_CISR)” , and the <i>eTPU Reference Manual</i> . The core must write 1 to clear CIS.
1 CIOS	Channel interrupt overflow status. 0 Interrupt overflow negated for this channel 1 Interrupt overflow asserted for this channel CIOS is mirrored in the ETPU_CIOSR. For more information on the ETPU_CIOSR and interrupt overflow, refer to Section 17.4.5.3, “eTPU Channel Interrupt Overflow Status Register (ETPU_CIOSR)” and the <i>eTPU Reference Manual</i> . The core must write 1 to clear CIOS.
2–7	Reserved.
8 DTRS	Data transfer request status. 0 Channel has no pending data transfer request. 1 Channel has a pending data transfer request. DTRS is mirrored in the ETPU_CDTRSR. For more information on the ETPU_CDTRSR and data transfer, refer to Section 17.4.5.2, “eTPU Channel Data Transfer Request Status Register (ETPU_CDTRSR)” and the <i>eTPU Reference Manual</i> . The core must write 1 to clear DTRS.
9 DTROS	Data transfer request overflow status. 0 Data transfer request overflow negated for this channel. 1 Data transfer request overflow asserted for this channel. DTROS is mirrored in the ETPU_CDTROS. Refer to Section 17.4.5.4, “eTPU Channel Data Transfer Request Overflow Status Register (ETPU_CDTROS)” and the <i>eTPU Reference Manual</i> for more information on ETPU_CDTROS and data transfer overflows. The core must write 1 to clear DTROS.
10–15	Reserved.
16 IPS	Channel input pin state. Shows the current value of the filtered channel input signal state
17 OPS	Channel output pin state. Shows the current value driven in the channel output signal, including the effect of the external output disable feature. If the channel input and output signals are connected to the same pad, OPS reflects the value driven to the pad. This is not necessarily the actual pad value, which drives the value in the IPS bit.
18–29	Reserved.
30–31 FM [0:1]	Channel function mode. ¹ Each function can use this field for specific configuration. These bits can be tested by microengine code.

¹ These bits are equivalent to the TPU/TPU2/TPU3 host sequence (HSQ) bits.

17.4.6.4 eTPU Channel *n* Host Service Request Register (ETPU_CnHSRR)

ETPU_CnHSRR is used by the device core to issue service requests to the channel.

Address: Channel_Register_Base + 0x0008

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 17-24. eTPU Channel *n* Host Service Request Register (ETPU_CnHSRR)

Table 17-27. ETPU_CnHSRR Field Descriptions

Field	Description
0–28	Reserved.
29–31 HSR [0:2]	Host service request. Used by the host core to request service to the channel <ul style="list-style-type: none"> • HSR = 000: no host service request pending • HSR > 000: function-dependent host service request pending. The HSR value turns to 000 automatically at the end of microengine service for that channel. The host must write HSR > 0 only when HSR = 0. Writing HSR = 000 withdraws a pending request if the scheduler has not started to resolve the entry point, however after the scheduler starts resolving, do not abort the service thread.

17.5 Functional Description

Refer to the *eTPU Reference Manual* for information regarding the functional description of the eTPU module.

17.6 Initialization/Application Information

After initial power-on reset, the eTPU remains in an idle state (except when debug is asserted on power-on reset—in this case, the microengine awakens in the halt state). In addition, initialize the SCM with the eTPU application prior to configuring the eTPU.

17.7 Document Revision History

Table 17-28. Changes Between MPC5565RM Revisions 0.1 and 1

Description of Change
<p>In Section 17.1.3, “eTPU Operation Overview”, changed:</p> <ul style="list-style-type: none"> FROM: “A thread may be interrupted only by resetting the entire eTPU module.” TO: “The core may terminate the thread by writing 1 to the FEND bit in the ETPUECR register.”
<p>In Section 17.1.4.1, “Time Bases” removed the words “or be driven by” from the sentence</p> <ul style="list-style-type: none"> FROM: “The TCRs may also drive or be driven by an eMIOS time base through the shared time and counter (STAC) bus, or they may be written by eTPU function software.” TO: It now reads “The TCRs may also drive an eMIOS time base through the shared time and counter (STAC) bus, or they may be written by eTPU function software.”
<p>Figure 18-3: changed title from SDM Write to SDM PSE Area Write.</p>
<p>In Section 17.1.5, “Features” changed:</p> <ul style="list-style-type: none"> FROM: “The first time base may be clocked by the system clock with programmable prescaler division from 2 to 512 (in steps of 2), or by the output of the second time base prescaler.” TO: “The first time base may be clocked by the system clock with programmable prescaler division from 2 to 512 (in steps of 2) <p>In Section 17.1.5, “Features” added this bullet:</p> <ul style="list-style-type: none"> “The second time base has a programmable prescaler that applies to all TCR2 clock inputs except the angle counter.” <p>In Section 17.1.5, “Features” changed:</p> <ul style="list-style-type: none"> FROM: “32-bit microengine registers and 24-bit resolution ALU, with 1 microcycle addition and subtraction, absolute value, bitwise logical operations on 24-bit, 16-bit, or byte operands: single bit manipulation, shift operations, sign extension and conditional execution.” TO: “24-bit registers and ALU, plus one 32-bit register for full-width SDM access” <p>In Section 17.1.5, “Features” added these bullets:</p> <ul style="list-style-type: none"> Hardware breakpoints on data access, qualified by address and/or data values. Hardware breakpoints on instruction address.
<p>In Section 17.3, “External Signal Description” corrected the number of external signals to 65 from 69. The four output disable input signals are now designated as internal signals.</p> <p>Changed wording in SCMMISF bit:</p> <ul style="list-style-type: none"> FROM: “This bit is automatically cleared when SCMMISEN changes from 0 to 1, or when global exception is cleared by writing 1 to GEC.” TO: “This bit is cleared by writing 1 to GEC.”
<p>In Section 17.4.3.4, “eTPU SCM Off-Range Data Register (ETPU_SCMOFFDATAR)” added a NOTE</p>
<p>In Section 17.4.3.5, “eTPU Engine Configuration Register (ETPU_ECR)” in the MDIS bit, changed the Note to read:</p> <ul style="list-style-type: none"> “After MDIS has been switched from 1 to 0 or vice-versa, do not switch its value again until STF switches to the same value.”
<p>In Section 17.4.3.5, “eTPU Engine Configuration Register (ETPU_ECR)” in the STF bit</p> <ul style="list-style-type: none"> removed the words “or after the STAC but stop has been asserted” from the STF bit description.
<p>In Table 17-11, “ETPU_TBR Field Descriptions, in the TCR2CTL field, removed the phrase</p> <ul style="list-style-type: none"> “TCR2 can also be clocked by an internal peripheral timebase signal” and changed TCR2CTL=101 to “Reserved.”

Chapter 18

Enhanced Queued Analog-to-Digital Converter (eQADC)

18.1 Introduction

The enhanced queued analog-to-digital converter (eQADC) provides accurate and fast conversions for a wide range of applications. The eQADC provides a parallel interface to two on-chip analog-to-digital converters (ADCs), and a single master to single slave serial interface to an off-chip external device. The two on-chip ADCs are architected to allow access to all the analog channels.

18.1.1 Block Diagram

Figure 18-1 shows the primary components inside the eQADC.

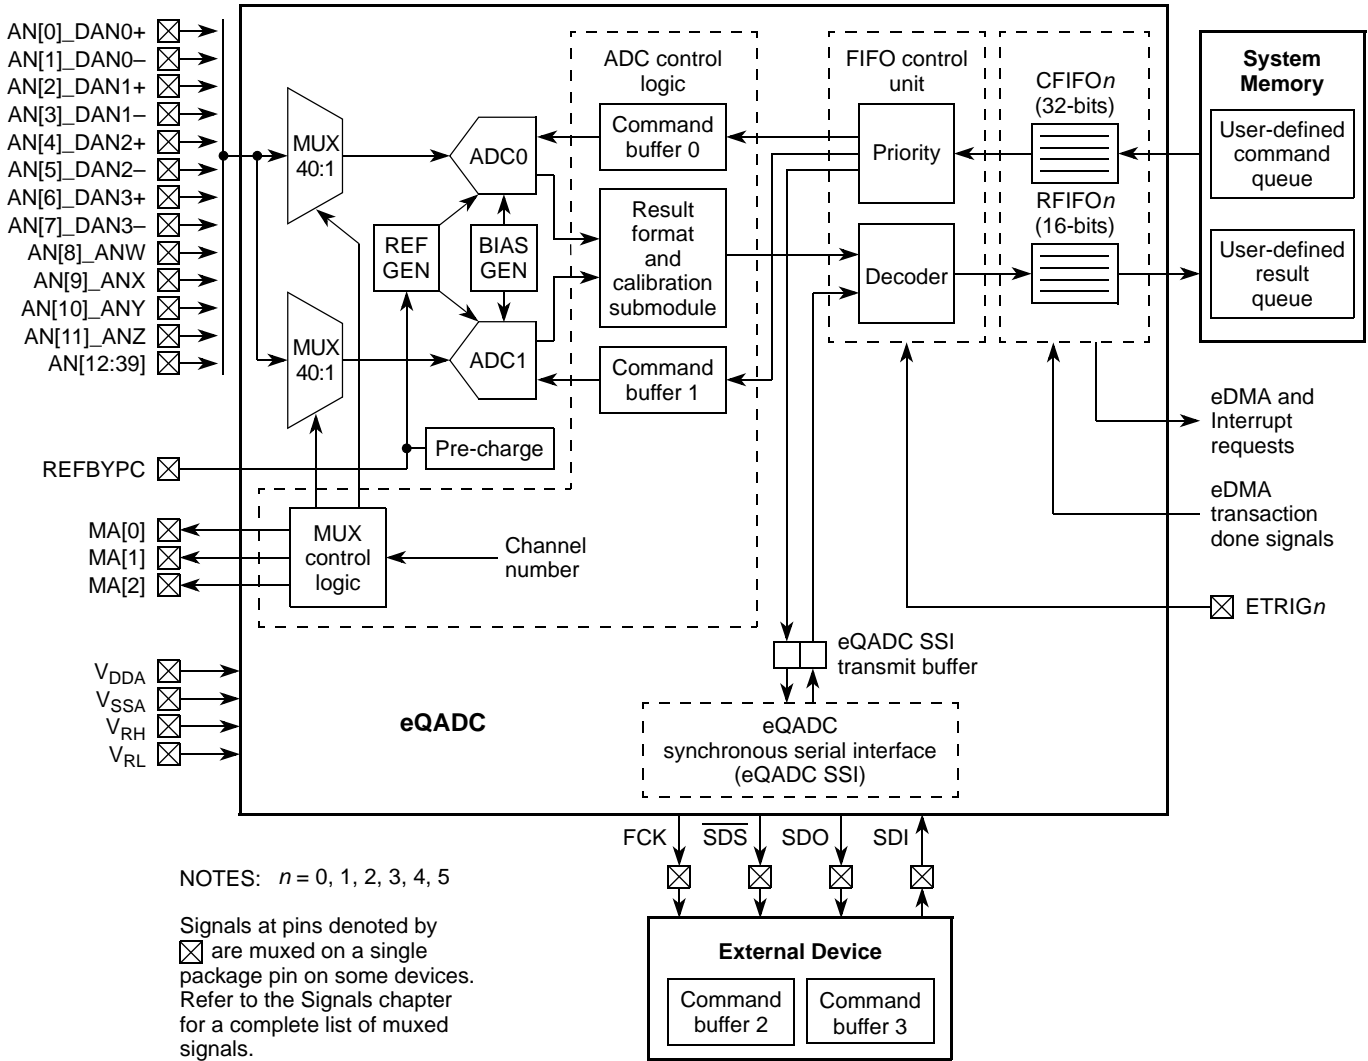

Figure 18-1. Simplified eQADC Block Diagram

18.1.2 Overview

The eQADC transfers commands from multiple command FIFOs (CFIFOs) to the on-chip ADCs or to the external device. The module can also in parallel (independently of the CFIFOs) receive data from the on-chip ADCs or from an off-chip external device into multiple result FIFOs (RFIFOs). The eQADC supports software and external hardware triggers from other modules to initiate transfers of commands from the CFIFOs to the on-chip ADCs or to the external device. (Refer to [Section 6.4.5.1, “eQADC External Trigger Input Multiplexing.”](#)) It also monitors the fullness of CFIFOs and RFIFOs, which may result in either underflow or overflow conditions. A CFIFO underflow occurs when the CFIFO is in the TRIGGERED state and it becomes empty. An RFIFO overflow occurs when an RFIFO is full and more data is ready to be moved to the RFIFO by the host CPU or by eDMA. Accordingly, the eQADC generates

eDMA or interrupt requests to control data movement between the FIFOs and the system memory, which is external to the eQADC.

The eQADC consists of the FIFO control unit which controls the CFIFOs and the RFIFOs, two ADCs with control logic, and the eQADC synchronous serial interface (eQADC SSI) which allows communication with an external device. There are six CFIFOs and six RFIFOs, each with four entries.

The FIFO control unit performs the following functions:

- Prioritizes the CFIFOs to determine which CFIFOs transfer commands
- Supports software and hardware triggers to start command transfers from a particular CFIFO
- Decodes command data from the CFIFOs and sends the commands to one of the two on-chip ADCs or to the external device
- Decodes result data from on-chip ADCs or from the external device, and transfers data to the RFIFO

The ADC control logic manages the execution of commands bound for on-chip ADCs from the CFIFOs and with the RFIFOs via the result format and calibration submodule. The ADC control logic performs the following functions:

- Buffers command data for execution
- Decodes command data and accordingly generates control signals for the two on-chip ADCs
- Formats and calibrates conversion result data coming from the on-chip ADCs
- Generates the internal multiplexer control signals and the select signals used by the external multiplexers

The eQADC SSI allows for a full duplex, synchronous, serial communication between the eQADC and an external device.

[Figure 18-1](#) also depicts data flow through the eQADC. Commands are contained in system memory in a user-defined queue data structure. Command data is moved from the user-defined command queue to the CFIFOs by either the host CPU or by the eDMA. After a CFIFO is triggered and becomes the highest priority, CFIFO command data is transferred from the CFIFO to the on chip ADCs, or to the external device. The ADC executes the command, and the result is moved through the result format and calibration submodule and to the RFIFO. The RFIFO target is specified by a field in the command that initiated the conversion. Data from the external device bypasses the result format and calibration submodule and is moved directly to its specified RFIFO. When data is stored in an RFIFO, data is moved from the RFIFO by the host CPU or by the eDMA to a data structure in system memory depicted in [Figure 18-1](#) as a user-defined result queue.

For users familiar with the QADC, the eQADC system upgrades the functionality provided by that module. Refer to [Section 18.5.7, “eQADC versus QADC,”](#) for a comparison between the eQADC and QADC.

18.1.3 Features

The eQADC includes these distinctive features:

- Two independent on-chip RSD cyclic ADCs
 - 12 bit AD resolution.
 - Targets up to 10 bit accuracy at 400 kilosamples per second ($ADC_CLK = 6\text{ MHz}$) and eight bit accuracy at 800 kilosamples per second ($ADC_CLK = 12\text{ MHz}$) for differential conversions.
 - Differential conversions (range -2.5 V to $+2.5\text{ V}$).
 - Single-ended signal range from $0-5\text{ V}$.
 - Sample times of two (default), 8, 64, or 128 ADC clock cycles.
 - Sample time stamp information when requested.
 - Parallel interface to eQADC CFIFOs and RFIFOs.
 - Supports both right-justified unsigned and signed formats for conversion results.
- Optional automatic application of ADC calibration constants
 - Provision of reference voltages ($25\% V_{REF}^1$ and $75\% V_{REF}$) for ADC calibration purposes
- 40 input channels available to the two on-chip ADCs
- Four pairs of differential analog input channels
- Full duplex synchronous serial interface to an external device
 - A free-running clock is provided for use by the external device.
 - Supports a 26-bit message length.
 - Transmits a null message when there are no triggered CFIFOs with commands bound for external command buffers, or when there are triggered CFIFOs with commands bound for external command buffers but the external command buffers are full.
- Priority-based CFIFOs
 - Supports six CFIFOs with fixed priority. The lower the CFIFO number, the higher its priority. When commands of distinct CFIFOs are bound for the same ADC, the higher priority CFIFO is always served first.
 - Supports software and several hardware trigger modes to arm a particular CFIFO.
 - Generates interrupt when command coherency is not achieved.
- External hardware triggers
 - Supports rising edge, falling edge, high level and low level triggers
 - Supports configurable digital filter
- Supports four external 8-to-1 muxes that can expand the input channel number from 40 to 68
- Upgrades the functionality provided by the QADC

1. $V_{REF} = V_{RH} - V_{RL}$.

18.1.4 Modes of Operation

This section describes the operating modes of the eQADC.

18.1.4.1 Normal Mode

This is the default operational mode when the eQADC is not in background debug or stop mode.

18.1.4.2 Debug Mode

Upon a debug mode entry request, eQADC behavior varies according to the status of the DBG field in [Section 18.3.2.1, “eQADC Module Configuration Register \(EQADC_MCR\).”](#) If DBG is programmed to 0b00, the debug mode entry request is ignored. If DBG is programmed to 0b10 or to 0b11, the eQADC enters debug mode. In case the eQADC SSI is enabled, the free running clock (FCK) output to external device does not stop when DBG is programmed to 0b11, but FCK stops in low phase, when DBG is programmed to 0b10.

During debug mode, the eQADC does not transfer commands from any CFIFOs, no null messages are transmitted to the external device, no data is returned to any RFIFO, no hardware trigger event is captured, and all eQADC registers can be accessed as in normal mode. Access to eQADC registers implies that CFIFOs can still be triggered using software triggers, because no scheme is implemented to write-protect registers during debug mode. eDMA and interrupt requests continue to be generated as in normal mode.

If at the time the debug mode entry request is detected, there are commands in the ADC that were already under execution, these commands are completed but the generated results, if any, are not sent to the RFIFOs until debug mode is exited. Commands that have not begun to execute are not executed until after exiting debug mode. The clock with an on-chip ADC stops, during its low phase, after the ADC stops executing commands. The time base counter only stops after all on-chip ADCs stop executing commands.

When exiting debug mode, the eQADC relies on the FIFO control unit and on the CFIFO status to determine the next command entry to transfer.

The eQADC internal behavior after the debug mode entry request is detected differs depending on the status of command transfers.

- No command transfer is in progress.
The eQADC immediately halts future command transfers from any CFIFO.
If a null message is being transmitted, eQADC completes the serial transmission before halting future command transfers. If valid data (conversion result or data read from an ADC register) is received by the result format and calibration submodule at the end of transmission, this data is not sent to an RFIFO until debug mode is exited.
If the null message transmission is aborted, the eQADC completes the abort procedure before halting future command transfers from any CFIFO. The message of the CFIFO that caused the abort of the previous serial transmission is transmitted only after exiting debug mode.
- Command transfer is in progress.
eQADC completes the transfer and updates CFIFO status before halting future command transfers from any CFIFO.

Command transfers to the external device are considered completed when the serial transmission of the command is completed. If valid data (conversion result or data read from an ADC register) is received at the end of a serial transmission, it is not sent to an RFIFO until debug mode is exited. The CFIFO status bits are still updated after the completion of the serial transmission, therefore, after debug mode entry request is detected, the eQADC status bits stop changing several system clock cycles after the on-going serial transmission completes.

If the command message transmission aborts, the eQADC completes the abort procedure before halting future command transfers from any CFIFO. The message of the CFIFO that caused the abort of the previous serial transmission is transmitted only after debug mode exits.

- Command/null message transfer through serial interface was aborted but next serial transmission did not start.

If the debug mode entry request is detected between the time a previous serial transmission was aborted and the start of the next transmission, the eQADC completes the abort procedure before halting future command transfers from any CFIFO. The message of the CFIFO that caused the abort of the previous serial transmission is transmitted only after debug mode exits.

18.1.4.3 Stop Mode

Upon a stop mode entry request detection, the eQADC progressively halts its operations until it reaches a static, stable state from which it can recover when returning to normal mode. The eQADC then asserts an acknowledge signal, indicating that it is static and that the clock input can be stopped. In stop mode, the free running clock (FCK) output to external device stops during its low phase if the eQADC SSI is enabled, and no hardware trigger events is captured. No capturing of hardware trigger events means that — as long as the system clock is running — CFIFOs can still be triggered using software triggers because no scheme is implemented to write-protect registers during stop mode.

If at the time the stop mode entry request is detected, there are commands in the ADC that were already under execution, these commands are completed but the generated results, if any, are not sent to the RFIFOs until stop mode is exited. Commands whose execution has not started do not execute until stop mode exits.

After these remaining commands are executed, the clock input to the ADCs is stopped. The time base counter stops after all on-chip ADCs cease executing commands and then the stop acknowledge signal is asserted. When exiting stop mode, the eQADC relies on the CFIFO operation modes and on the CFIFO status to determine the next command entry to transfer.

The eQADC internal behavior after the stop mode entry request is detected differs depending on the status of the command transfer.

- No command transfer is in progress

The eQADC immediately halts future command transfers from any CFIFO.

If a null message is being transmitted, eQADC completes the transmission before halting future command transfers. If valid data (conversion result or data read from an ADC register) is received at the end of the transmission, it is not sent to an RFIFO until stop mode exits.

If the null message transmission is aborted, the eQADC completes the abort procedure before halting future command transfers from any CFIFO. The message of the CFIFO that caused the abort of the previous serial transmission is only transmitted after stop mode exits.

- Command transfer is in progress.

The eQADC completes the transfer and update CFIFO status before halting future command transfers from any CFIFO.

Command transfers to the external device are considered completed when the serial transmission of the command is completed. If valid data (conversion result or data read from an ADC register) is received at the end of a serial transmission, it is not sent to an RFIFO until stop mode exits. The CFIFO status bits are still updated after the completion of the serial transmission, therefore, after stop mode entry request is detected, the eQADC status bits stop changing several system clock cycles after the on-going serial transmission completes.

If the command message transmission is aborted, the eQADC completes the abort procedure before halting future command transfers from any CFIFO. The message of the CFIFO that caused the abort of the previous serial transmission are transmitted only after stop mode exits.

- Command/null message transfer through serial interface was aborted but next serial transmission did not start.

If the stop mode entry request is detected between the time a previous serial transmission was aborted and the start of the next transmission, the eQADC completes the abort procedure before halting future command transfers from any CFIFO. The message of the CFIFO that caused the abort of the previous serial transmission is transferred only after stop mode is exited.

18.2 External Signal Description

These signals are external to the eQADC module, but may or may not be physical pins. Refer to [Chapter 2, “Signal Description”](#) for a complete list of all physical pins and signals.

Table 18-1. eQADC External Signals

Function	Description	I/O Type	Status During Reset ¹	Status After Reset ²	Type	Package

Table 18-1. eQADC External Signals (continued)

Function	Description	I/O Type	Status During Reset ¹	Status After Reset ²	Type	Package
V _{DDA}	Analog positive power supply	I	N/A	V _{DDA}	Power	496 324
V _{SSA}	Analog negative power supply	I	N/A	V _{SSA}	Power	496 324

¹ Terminology is O — output, I — input, Up — weak pullup enabled, Down — weak pulldown enabled, Low — output driven low, High — output driven high. A dash on the left side of the slash denotes that both the input and output buffers for the pin are off. A dash on the right side of the slash denotes that there is no weak pullup/down enabled on the pin. The signal name to the left or right of the slash indicates the pin is enabled.

² Function after reset of GPI is general-purpose input. A dash on the left side of the slash denotes that both the input and output buffers for the pin are off. A dash on the right side of the slash denotes that there is no weak pullup/down enabled on the pin.

18.3 Memory Map and Register Definition

This section provides memory maps and detailed descriptions of all registers. Data written to or read from reserved areas of the memory map is undefined.

18.3.1 eQADC Memory Map

This section provides memory maps for the eQADC.

Table 18-2. eQADC Memory Map

Address	Register Name	Register Description	Bits
Base (0xFFFF8_0000)	EQADC_MCR	EQADC module configuration register	32
Base + 0x004	—	Reserved	—
Base + 0x008	EQADC_NMSFR	eQADC null message send format register	32

18.3.2 eQADC Register Descriptions

18.3.2.1 eQADC Module Configuration Register (EQADC_MCR)

The EQADC_MCR contains bits used to control how the eQADC responds to a debug mode entry request, and to enable the eQADC SSI interface.

Address: Base+ 0x000

Access: R/W

Figure 18-2. eQADC Module Configuration Register (EQADC_MCR)

Table 18-3. EQADC_MCR Field Descriptions

Field	Description
0–26	Reserved.
27–28 ESSIE [0:1]	eQADC synchronous serial interface enable. Defines the eQADC synchronous serial interface operation. 00 eQADC SSI is disabled 01 Invalid value 10 eQADC SSI is enabled, FCK is free running, and serial transmissions are disabled 11 eQADC SSI is enabled, FCK is free running, and serial transmissions are enabled
29	Reserved.
30–31 DBG [0:1]	Debug enable. Defines the eQADC response to a debug mode entry request. 00 Do not enter debug mode 01 Invalid value 10 Enter debug mode. If the eQADC SSI is enabled, FCK stops while the eQADC is in debug mode. 11 Enter debug mode. If the eQADC SSI is enabled, FCK is free running while the eQADC is in debug mode

NOTE

Disabling the eQADC SSI (0b00 write to ESSIE) or serial transmissions from the eQADC SSI (0b10 write to ESSIE) while a serial transmission is in progress results in the abort of that transmission.

NOTE

When disabling the eQADC SSI, the FCK does not stop until it reaches its low phase.

18.3.2.2 eQADC Null Message Send Format Register (EQADC_NMSFR)

The EQADC_NMSFR defines the format of the null message sent to the external device.

Address: Base + 0x008

Access: Read/Write

Figure 18-3. eQADC Null Message Send Format Register (EQADC_NMSFR)

Table 18-4. EQADC_NMSFR Field Descriptions

Field	Description
0–5	Reserved.
6–31 NMF [0:25]	<p>Null message format. Contains the programmable null message send value for the eQADC. The value written to this register is sent as a null message when serial transmissions from the eQADC SSI are enabled (ESSIE field is configured to 0b11 in EQADC_MCR (Section 18.3.2.1, “eQADC Module Configuration Register (EQADC_MCR)”) and either</p> <ul style="list-style-type: none"> • there are no triggered CFIFOs with commands bound for external command buffers, or; • there are triggered CFIFOs with commands bound for external command buffers but the external command buffers are full. <p>Refer to Section , “Null Message Format for External Device Operation” for more information on the format of a null message.</p>

NOTE

The eQADC null message send format register only affects how the eQADC sends a null message, but it has no control on how the eQADC detects a null message on receiving data. The eQADC detects a null message by decoding the MESSAGE_TAG field on the receive data. Refer to Table 18-34 for more information on the MESSAGE_TAG field.

NOTE

Writing to the eQADC null message send format register while serial transmissions are enabled is not recommended. Refer to EQADC_MCR[ESSIE] field in Section 18.3.2.1, “eQADC Module Configuration Register (EQADC_MCR).”

18.3.2.3 eQADC External Trigger Digital Filter Register (EQADC_ETDFR)

The EQADC_ETDFR is used to set the minimum time a signal must be held in a logic state on the CFIFO triggers inputs to be recognized as an edge or level gated trigger. The digital filter length field specifies the

minimum number of system clocks that must be counted by the digital filter counter to recognize a logic state change.

Address: Base + 0x00C

Access: Read/Write

0b1100	4097	34141.67
0b1101	8193	68275.00
0b1110	16385	136541.67
0b1111	32769	273075.00

18.3.2.4 eQADC CFIFO Push Registers 0–5 (EQADC_CFPR n)

The EQADC_CFPRs provide a mechanism to fill the CFIFOs with command messages from the command queues. Refer to [Section 18.4.3, “eQADC Command FIFOs,”](#) for more information on the CFIFOs and to [Section 18.4.1.2, “Message Format in eQADC,”](#) for a description on command message formats.

Address: Base + 0x010 (EQADC_CFPR0)
 Base + 0x014 (EQADC_CFPR1);
 Base + 0x018 (EQADC_CFPR2)
 Base + 0x01C (EQADC_CFPR3)

Figure 18-5. eQADC CFIFO Push Registers 0–5 (EQADC_CFPR n)
Table 18-7. EQADC_CFPR n Field Descriptions

Field	Description
0–31 CF_PUSH n [0:31]	CFIFO push data n . When CFIFO n is not full, writing to the whole word or any bytes of EQADC_CFPR n pushes the 32-bit CF_PUSH n value into CFIFO n . Writing to the CF_PUSH n field also increments the corresponding CFCTR n value by one in Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)” . When the CFIFO n is full, the eQADC ignores any write to the CF_PUSH n . Reading the EQADC_CFPR n always returns 0. Note: Only whole words must be written to EQADC_CFPR. Writing halfwords or bytes to EQADC_CFPR pushes the entire 32-bit CF_PUSH field into the CFIFO, but undefined data fills the areas of CF_PUSH that were not specifically designated as target locations for the write.

18.3.2.5 eQADC Result FIFO Pop Registers 0–5 (EQADC_RFPR n)

The eQADC_RFPRs provide a mechanism to retrieve data from RFIFOs.

NOTE

The EQADC_RFPR n must not be read speculatively. For future compatibility, the TLB entry covering the EQADC_RFPR n must be configured to be guarded.

Address: Base + 0x030 (EQADC_RFPR0)
 Base + 0x034 (EQADC_RFPR1)
 Base + 0x038 (EQADC_RFPR2)
 Base + 0x03C (EQADC_RFPR3)

Figure 18-6. eQADC RFIFO Pop Registers 0–5 (EQADC_RFPR n)

Table 18-8. EQADC_RFPR n Field Descriptions

Field	Description
0–15	Reserved.
16–31 RF_POP n [0:15]	Result FIFO pop data n . When RFIFO n is not empty, the RF_POP n contains the next unread entry value of RFIFO n . Reading the whole word, a halfword, or any bytes of EQADC_RFPR n pops one entry from RFIFO n , and the RFCTR n value is decremented by 1. Refer to Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn).” When the RFIFO n is empty, any read on EQADC_RFPR n returns undefined data value and does not decrement the RFCTR n value. Writing to EQADC_RFPR n has no effect.

18.3.2.6 eQADC CFIFO Control Registers 0–5 (EQADC_CFCR n)

The eQADC_CFCRs contain bits that affect CFIFOs. These bits specify the CFIFO operation mode and can invalidate all of the CFIFO contents.

Address: EQADC_BASE + 0x050 (EQADC_CFCR0)
 EQADC_BASE + 0x052 (EQADC_CFCR1)
 EQADC_BASE + 0x054 (EQADC_CFCR2)

Figure 18-7. eQADC CFIFO Control Registers (EQADC_CFCR_n)

Table 18-9. EQADC_CFCR_n Field Descriptions

Field	Description
0–4	Reserved.
5 SSE _n	CFIFO single-scan enable bit <i>n</i> . Used to set the SSS _n bit, as described in Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISR_n)” . Writing a 1 to SSE _n sets the SSS _n if the CFIFO is in single-scan mode. When SSS _n is already asserted, writing a 1 to SSE _n has no effect. If the CFIFO is in continuous-scan mode or is disabled, writing a 1 to SSE _n does not set SSS _n . Writing a 0 to SSE _n has no effect. SSE _n always is read as 0. 0 No effect. 1 Set the SSS _n bit.
6 CFINV _n	CFIFO invalidate bit <i>n</i> . Causes the eQADC to invalidate all entries of CFIFO _n . Writing a 1 to CFINV _n resets the value of CFCTR _n in the EQADC_FISR register (refer to Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISR_n)”). Writing a 1 to CFINV _n also resets the push next data pointer, transfer next data pointer to the first entry of CFIFO _n in Figure 18-35 . Reading CFINV _n always returns a 0. Writing a 0 has no effect. 0 No effect. 1 Invalidate all of the entries in the corresponding CFIFO. Note: Writing CFINV _n only invalidates commands stored in CFIFO _n ; previously transferred commands that are waiting for execution (commands stored in the ADC command buffers) are executed, and the results are stored in the RFIFO. Note: Do not write to CFINV _n unless MODE _n is disabled, and CFIFO status is IDLE.
7	Reserved.
8–11 MODE _n [0:3]	CFIFO operation mode <i>n</i> . Selects the CFIFO operation mode for CFIFO _n . Refer to Section 18.4.3.5, “CFIFO Scan Trigger Modes,” for more information on CFIFO trigger mode. Note: If MODE _n is not disabled, it must not be changed to any other mode besides disabled. If MODE _n is disabled and the CFIFO status is IDLE, MODE _n can be changed to any other mode.
12–15	Reserved.

Figure 18-8. eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCR_n)

Table 18-11. EQADC_IDCR n Field Descriptions

Field	Description
0 NCIE n	<p>Non-coherency interrupt enable n. Enables the eQADC to generate an interrupt request when the corresponding NCFn, described in Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)”, is asserted.</p> <p>0 Disable non-coherency interrupt request 1 Enable non-coherency interrupt request</p>
1 TORIE n	<p>Trigger overrun interrupt enable n. Enables the eQADC to generate an interrupt request when the corresponding TORFn (described in Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)”) is asserted.</p> <p>Apart from generating an independent interrupt request for a CFIFOn trigger overrun event, the eQADC also provides a combined interrupt at which the result FIFO overflow interrupt, the command FIFO underflow interrupt, and the command FIFO trigger overrun interrupt requests of all CFIFOs are ORed. When RFOIEn, CFUIEn, and TORIEn are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOFn, CFUFn, and TORFn (assuming that all interrupts are enabled). Refer to Section 18.4.7, “eQADC eDMA/Interrupt Request,” for details.</p> <p>0 Disable trigger overrun interrupt request 1 Enable trigger overrun interrupt request</p>
2 PIE n	<p>Pause interrupt enable n. Enables the eQADC to generate an interrupt request when the corresponding PFx in EQADC_FISRn is asserted. Refer to Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)”.</p> <p>0 Disable pause interrupt request 1 Enable pause interrupt request</p>
3 EOQIE n	<p>End-of-queue interrupt enable n. Enables the eQADC to generate an interrupt request when the corresponding EOQFn in EQADC_FISRn is asserted. Refer to Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)”.</p> <p>0 Disable end of queue interrupt request. 1 Enable end of queue interrupt request.</p>
4 CFUIE n	<p>CFIFO underflow interrupt enable n. Enables the eQADC to generate an interrupt request when the corresponding CFUFn in EQADC_FISRn is asserted.</p> <p>Apart from generating an independent interrupt request for a CFIFOn underflow event, the eQADC also provides a combined interrupt at which the result FIFO overflow interrupt, the command FIFO underflow interrupt, and the command FIFO trigger overrun interrupt requests of all CFIFOs are ORed. When RFOIEn, CFUIEn, and TORIEn are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOFn, CFUFn, and TORFn (assuming that all interrupts are enabled). Refer to Section 18.4.7, “eQADC eDMA/Interrupt Request,” for details.</p> <p>0 Disable underflow interrupt request 1 Enable underflow interrupt request</p>
5	Reserved.
6 CFFE n	<p>CFIFO fill enable n. Enables the eQADC to generate an interrupt request (CFFSn is asserted) or eDMA request (CFFSn is negated) when CFFFn in EQADC_FISRn is asserted. Refer to Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)”.</p> <p>0 Disable CFIFO fill eDMA or interrupt request 1 Enable CFIFO fill eDMA or interrupt request</p> <p>Note: CFFEn must not be negated while an eDMA transaction is in progress.</p>
7 CFFS n	<p>CFIFO fill select n. Selects if an eDMA or interrupt request is generated when CFFFn in EQADC_FISRn (Refer to Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)”) is asserted. If CFFEn is asserted, the eQADC generates an interrupt request when CFFSn is negated, or it generates an eDMA request if CFFSn is asserted.</p> <p>0 Generate interrupt request to move data from the system memory to CFIFOn. 1 Generate eDMA request to move data from the system memory to CFIFOn.</p> <p>Note: CFFSn must not be negated while an eDMA transaction is in progress.</p>

Table 18-11. EQADC_IDCR n Field Descriptions (continued)

Field	Description
8–11	Reserved.
12 RFOIE n	<p>RFIFO overflow interrupt enable n. Enables the eQADC to generate an interrupt request when the corresponding RFOFn in EQADC_FISRn is asserted. Refer to Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)”.</p> <p>Apart from generating an independent interrupt request for an RFIFOn overflow event, the eQADC also provides a combined interrupt at which the result FIFO overflow Interrupt, the command FIFO underflow interrupt, and the command FIFO trigger overrun interrupt requests of all CFIFOs are ORed. When RFOIEn, CFUIEn, and TORIEn are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOFn, CFUFn, and TORFn (assuming that all interrupts are enabled). Refer to Section 18.4.7, “eQADC eDMA/Interrupt Request,” for details.</p> <p>0 Disable overflow interrupt request 1 Enable overflow Interrupt request</p>
13	Reserved.
14 RFDE n	<p>RFIFO drain enable n. Enables the eQADC to generate an interrupt request (RFDSn is asserted) or eDMA request (RFDSn is negated) when RFDFn in EQADC_FISRn (Refer to Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)”) is asserted.</p> <p>0 Disable RFIFO drain eDMA or interrupt request 1 Enable RFIFO drain eDMA or interrupt request</p> <p>Note: RFDEn must not be negated while an eDMA transaction is in progress.</p>
15 RFDS n	<p>RFIFO drain select n. Selects if an eDMA or interrupt request is generated when RFDFn in EQADC_FISRn (Refer to Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn)”) is asserted. If RFDEn is asserted, the eQADC generates an interrupt request when RFDSn is negated, or it generates an eDMA request when RFDSn is asserted.</p> <p>0 Generate interrupt request to move data from RFIFn to the system memory 1 Generate eDMA request to move data from RFIFOn to the system memory</p> <p>Note: RFDSn must not be negated while an eDMA transaction is in progress.</p>

18.3.2.8 eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISR n)

The EQADC_FISRs contain flag and status bits for each CFIFO and RFIFO pair. Writing 1 to a flag bit clears it. Writing 0 has no effect. Status bits are read only. These bits indicate the status of the FIFO itself.

Figure 18-9. eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISR_n)

Table 18-12. EQADC_FISR_n Field Descriptions

Field	Description
0 NCF _n	<p>Non-coherency flag <i>n</i>. NCF_n is set whenever a command sequence being transferred through CFIFO_n becomes non-coherent. If NCIE_n in EQADC_IDCR_n (Refer to Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCR_n)”) and NCF_n are asserted, an interrupt request is generated. Writing a 1 clears NCF_n. Writing a 0 has no effect. More for information on non-coherency refer to Section 18.4.3.6.5, “Command Sequence Non-Coherency Detection.”</p> <p>0 Command sequence being transferred by CFIFO_n is coherent 1 Command sequence being transferred by CFIFO_n became non-coherent</p> <p>Note: Non-coherency means that a command in the command FIFO was not immediately executed, but delayed. This may occur if the command is pre-empted, where a higher priority queue is triggered and has a competing conversion command for the same converter.</p>
1 TORF _n	<p>Trigger overrun flag for CFIFO <i>n</i>. TORF_n is set when trigger overrun occurs for the specified CFIFO in edge or level trigger mode. Trigger overrun occurs when an already triggered CFIFO receives an additional trigger. When EQADC_IDCR_n[TORIE_n] is set (Refer to Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCR_n)”) and TORF_n are asserted, an interrupt request is generated.</p> <p>Apart from generating an independent interrupt request for a CFIFO_n trigger overrun event, the eQADC also provides a combined interrupt at which the result FIFO overflow interrupt, the command FIFO underflow interrupt, and the command FIFO trigger overrun Interrupt requests of all CFIFOs are ORed. When RFOIE_n, CFUIE_n, and TORIE_n are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOF_n, CFUF_n, and TORF_n (assuming that all interrupts are enabled). Refer to Section 18.4.7, “eQADC eDMA/Interrupt Request,” for details.</p> <p>Write 1 to clear the TORF_n bit. Writing 0 has no effect.</p> <p>0 No trigger overrun occurred 1 Trigger overrun occurred</p> <p>Note: The trigger overrun flag is not set for CFIFOs configured for software trigger mode.</p>

Table 18-12. EQADC_FISR n Field Descriptions (continued)

Field	Description
<p>2 PFn</p>	<p>Pause flag n. PF behavior changes according to the CFIFO trigger mode.</p> <ul style="list-style-type: none"> In edge trigger mode, PFn is set when the eQADC completes the transfer of an entry with an asserted pause bit from CFIFOn. In level trigger mode, when CFIFOn is in the TRIGGERED state, PFn is set when CFIFO status changes from TRIGGERED due to the detection of a closed gate. <p>An interrupt routine, generated due to the asserted PF, can be used to verify if a complete scan of the user-defined command queue was performed. If a closed gate is detected while no command transfers are taking place, it has an immediate effect on the CFIFO status. If a closed gate is detected while a command transfer to an on-chip ADC is taking place, it only affects the CFIFO status when the transfer completes. If a closed gate is detected during the serial transmission of a command to the external device, it has no effect on the CFIFO status until the transmission completes.</p> <p>The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate ADC command buffer. The transfer of entries bound for the external device is considered completed when the serial transmission of the entry is completed. In software trigger mode, PFn is never asserted.</p> <p>If PIEn (Refer to Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCRn)”) and PFn are asserted, an interrupt is generated. Writing a 1 clears the PFn. Writing a 0 has no effect. Refer to Section 18.4.3.6.3, “Pause Status,” for more information on pause flag.</p> <p>0 Entry with asserted pause bit was not transferred from CFIFOn (CFIFO in edge trigger mode), or CFIFO status did not change from the TRIGGERED state due to detection of a closed gate (CFIFO in level trigger mode).</p> <p>1 Entry with asserted pause bit was transferred from CFIFOn (CFIFO in edge trigger mode), or CFIFO status changes from the TRIGGERED state due to detection of a closed gate (CFIFO in level trigger mode).</p> <p>Note: In edge trigger mode, an asserted PFn only implies that the eQADC has finished transferring a command with an asserted pause bit from CFIFOn. It does not imply that result data for the current command and for all previously transferred commands has been returned to the appropriate RFIFO.</p> <p>Note: In software or level trigger mode, when the eQADC completes the transfer of an entry from CFIFOn with an asserted pause bit, PFn is not set and commands continue to transfer without pausing.</p>
<p>3 EOQFn</p>	<p>End-of-queue flag n. Indicates that an entry with an asserted EOQ bit was transferred from CFIFOn to the on-chip ADCs or to the external device. Refer to Section 18.4.1.2, “Message Format in eQADC,” for details about command message formats. When the eQADC completes the transfer of an entry with an asserted EOQ bit from CFIFOn, EOQFn is set. The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate command buffer. The transfer of entries bound for the external device is considered completed when the serial transmission of the entry is completed. If the EOQIEn bit (Refer to Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCRn)”) and EOQFn are asserted, an interrupt is generated. Writing a 1 clears the EOQFn bit. Writing a 0 has no effect. Refer to Section 18.4.3.6.2, “Command Queue Completion Status,” for more information on end-of-queue flag.</p> <p>0 Entry with asserted EOQ bit was not transferred from CFIFOn</p> <p>1 Entry with asserted EOQ bit was transferred from CFIFOn</p> <p>Note: An asserted EOQFn only implies that the eQADC has finished transferring a command with an asserted EOQ bit from CFIFOn. It does not imply that result data for the current command and for all previously transferred commands has been returned to the appropriate RFIFO.</p>

Table 18-12. EQADC_FISR n Field Descriptions (continued)

Field	Description
4 CFUF n	<p>CFIFO underflow flag n. Indicates an underflow event on CFIFOn. CFUFn is set when CFIFOn is in the TRIGGERED state and it becomes empty. No commands are transferred from an underflowing CFIFO, and command transfers from lower priority CFIFOs are not blocked. When CFUIEn (see Section Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCRn)”) and CFUFn are both asserted, the eQADC generates an interrupt request.</p> <p>Apart from generating an independent interrupt request for a CFIFOn underflow event, the eQADC also provides a combined interrupt at which the result FIFO overflow interrupt, the command FIFO underflow interrupt, and the command FIFO trigger overrun interrupt requests of all CFIFOs are ORed. When RFOIEn, CFUIEn, and TORIEn are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOFn, CFUFn, and TORFn (assuming that all interrupts are enabled). Refer to Section 18.4.7, “eQADC eDMA/Interrupt Request,” for details. Writing a 1 clears CFUFn. Writing a 0 has no effect.</p> <p>0 No CFIFO underflow event occurred 1 A CFIFO underflow event occurred</p>
5 SSS n	<p>CFIFO single-scan status bit n. When asserted, enables the detection of trigger events for CFIFOs programmed into single-scan level- or edge-trigger mode, and works as trigger for CFIFOs programmed into single-scan software-trigger mode. Refer to Section 18.4.3.5.2, “Single-Scan Mode,” for further details. The SSSn bit is set by writing a 1 to the SSEn bit (see Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 (EQADC_CFCRn)”). The eQADC clears the SSSn bit when a command with an asserted EOQ bit is transferred from a CFIFO in single-scan mode, when a CFIFO is in single-scan level trigger mode and its status changes from the TRIGGERED state due to the detection of a closed gate, or when the value of the CFIFO operation mode MODEn (see Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 (EQADC_CFCRn)”) is changed to disabled. Writing to SSSn has no effect. SSSn has no effect in continuous-scan or in disabled mode.</p> <p>0 CFIFO in single-scan, level-, or edge-trigger mode ignores trigger events, or CFIFO in single-scan software-trigger mode is not triggered. 1 CFIFO in single-scan level- or edge-trigger mode detects a trigger event, or CFIFO in single-scan software-trigger mode is triggered.</p>
6 CFFF n	<p>CFIFO fill flag n. CFFFn is set when the CFIFOn is not full. When CFFEn (see Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCRn)”) and CFFFn are both asserted, an interrupt or an eDMA request is generated depending on the status of the CFFSn bit. When CFFSn is negated (interrupt requests selected), software clears CFFFn by writing a 1 to it. Writing a 0 has no effect. When CFFSn is asserted (eDMA requests selected), CFFFn is automatically cleared by the eQADC when the CFIFO becomes full.</p> <p>0 CFIFOn is full. 1 CFIFOn is not full.</p> <p>Note: When generation of interrupt requests is selected (CFFSn=0), CFFFn must only be cleared in the ISR after the CFIFOn push register is accessed. Note: CFFFn should not be cleared when CFFSn is asserted (eDMA requests selected).</p>
7–11	Reserved.

Table 18-12. EQADC_FISR n Field Descriptions (continued)

Field	Description
12 RFOF n	<p>RFIFO overflow flag n. Indicates an overflow event on RFIFOn. RFOFn is set when RFIFOn is already full, and a new data is received from the on-chip ADCs or from the external device. The RFIFOn does not overwrite older data in the RFIFO, and the new data is ignored. When RFOIEn (see Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCRn)”) and RFOFn are both asserted, the eQADC generates an interrupt request.</p> <p>Apart from generating an independent interrupt request for an RFIFOn overflow event, the eQADC also provides a combined interrupt at which the result FIFO overflow interrupt, the command FIFO underflow interrupt, and the command FIFO trigger overrun interrupt requests of all CFIFOs are ORed. When RFOIEn, CFUIEn, and TORIEn are all asserted, this combined interrupt request is asserted whenever one of the following 18 flags becomes asserted: RFOFn, CFUFn, and TORFn (assuming that all interrupts are enabled). Refer to Section 18.4.7, “eQADC eDMA/Interrupt Request,” for details.</p> <p>Write 1 to clear RFOFn. Writing a 0 has no effect.</p> <p>0 No RFIFO overflow event occurred. 1 An RFIFO overflow event occurred.</p>
13	Reserved.
14 RFDF n	<p>RFIFO drain flag n. Indicates if RFIFOn has valid entries that can be drained or not. RFDFn is set when the RFIFOn has at least one valid entry in it. When RFDEn (see Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCRn)”) and RFDFn are both asserted, an interrupt or an eDMA request is generated depending on the status of the RFDSn bit. When RFDSn is negated (interrupt requests selected), software clears RFDFn by writing a 1 to it. Writing a 0 has no effect. When RFDSn is asserted (eDMA requests selected), RFDFn is automatically cleared by the eQADC when the RFIFO becomes empty.</p> <p>0 RFIFOn is empty. 1 RFIFOn has at least one valid entry.</p> <p>Note: In the interrupt service routine, RFDF must be cleared only after the RFIFOn pop register is read. Note: RFDFn should not be cleared when RFDSn is asserted (eDMA requests selected).</p>
15	Reserved.
16–19 CFCTR n [0:3]	<p>CFIFOn entry counter. Indicates the number of commands stored in the CFIFOn. When the eQADC completes transferring a piece of new data from the CFIFOn, it decrements CFCTRn by 1. Writing a word or any bytes to the corresponding CFIFO Push Register (see Section 18.3.2.4, “eQADC CFIFO Push Registers 0–5 (EQADC_CFPRn)”) increments CFCTRn by 1. Writing any value to CFCTRn has no effect.</p>
20–23 TNX TPTR n [0:3]	<p>CFIFOn transfer next pointer. Indicates the index of the next entry to be removed from CFIFOn when it completes a transfer. When TNXTPTRn is 0, it points to the entry with the smallest memory-mapped address inside CFIFOn. TNXTPTRn is only updated when a command transfer is completed. If the maximum index number (CFIFO depth minus 1) is reached, TNXTPTRn is wrapped to 0, else, it is incremented by 1. For details refer to Section 18.4.3.1, “CFIFO Basic Functionality.” Writing any value to TNXTPTRn has no effect.</p>
24–27 RFCTR n [0:3]	<p>RFIFOn entry counter. Indicates the number of data items stored in the RFIFOn. When the eQADC stores a piece of new data into RFIFOn, it increments RFCTRn by 1. Reading the whole word, halfword or any bytes of the corresponding Result FIFO pop register (see Section 18.3.2.5, “eQADC Result FIFO Pop Registers 0–5 (EQADC_RFPRn)”) decrements RFCTRn by 1. Writing any value to RFCTRn itself has no effect.</p>
28–31 POPNX TPTR n [0:3]	<p>RFIFOn pop next pointer. Indicates the index of the entry that is returned when EQADC_RFPRn is read. When POPNXTPTRn is 0, it points to the entry with the smallest memory-mapped address inside RFIFOn. POPNXTPTRn is updated when EQADC_RFPRn is read. If the maximum index number (RFIFO depth minus 1) is reached, POPNXTPTRn is wrapped to 0, else, it is incremented by 1. For details refer to Section 18.4.4.1, “RFIFO Basic Functionality.” Writing any value to POPNXTPTRn has no effect.</p>

18.3.2.9 eQADC CFIFO Transfer Counter Registers 0–5 (EQADC_CFTCR n)

The EQADC_CFTCRs record the number of commands transferred from a CFIFO. The EQADC_CFTCR supports the monitoring of command transfers from a CFIFO.

Address: EQADC_BASE + 0x090 (EQADC_CFTCR0)

Access: Read/Write

EQADC_BASE + 0x092 (EQADC_CFTCR1)

EQADC_BASE + 0x094 (EQADC_CFTCR2)

EQADC_BASE + 0x096 (EQADC_CFTCR3)

EQADC_BASE + 0x098 (EQADC_CFTCR4)

Figure 18-10. eQADC CFIFO Transfer Counter Registers (EQADC_CFTCR n)

Table 18-13. EQADC_CFTCR n Field Descriptions

Field	Description
0–4	Reserved.
5–15 TC_CF n [0:10]	Transfer counter for CFIFO n . TC_CF n counts the number of commands that have been completely transferred from CFIFO n . TC_CF n =2, for example, signifies that two commands have been transferred. The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate command buffer. The transfer of entries bound for an external device is considered completed when the serial transmission of the entry is completed. The eQADC increments the TC_CF n value by 1 after a command is transferred. TC_CF n resets to 0 after eQADC completes transferring a command with an asserted EOQ bit. Writing any value to TC_CF n sets the counter to that written value. Note: If CFIFO n is in the TRIGGERED state when its MODE n field is programmed to disabled, the exact number of entries transferred from the CFIFO until that point (TC_CF n) is only known after the CFIFO status changes to IDLE, as indicated by CFS n . For details refer to Section 18.4.3.5.1, “Disabled Mode.”

18.3.2.10 eQADC CFIFO Status Snapshot Registers 0–2 (EQADC_CFSSR n)

The EQADC_CFSSRs contain status fields to track the operation status of each CFIFO and the transfer counter of the last CFIFO to initiate a command transfer to the internal ADCs and the external command buffers. EQADC_CFSSR0–1 are related to the on-chip ADC command buffers (buffers 0 and 1) while EQADC_CFSSR2 is related to the external command buffers (buffers 2 and 3). All fields of a particular EQADC_CFSSR are captured at the beginning of a command transfer to the buffer associated with that register.

Note that captured status register values are associated with a previous command transfer. This means that the EQADC_CFSSR registers capture the status registers before the status registers change, because of the transfer of the current command that is about to be popped from the CFIFO. The EQADC_CFSSRs are read only. Writing to the EQADC_CFSSRs has no effect.

Figure 18-15. eQADC SSI Control Register (EQADC_SSICR)

Table 18-19. EQADC_SSICR Field Descriptions

Field	Description
0–20	Reserved.
21–23 MDT [0:2]	Minimum delay after transmission. Defines the minimum delay after transmission time (t_{MDT}) expressed in serial clock (FCK) periods. t_{MDT} is the minimum time SDS should be kept negated between two consecutive serial transmissions. Table 18-20 lists the minimum delay after transfer time according to how MDT is set. The MDT field must only be written when the serial transmissions from the eQADC SSI are disabled - Refer to EQADC_MCR[ESSIE] field in Section 18.3.2.1, “eQADC Module Configuration Register (EQADC_MCR)” .
24–27	Reserved.
28–31 BR [0:3]	Baud rate. Selects system clock divide factor as shown in Table 18-21 . The baud clock is calculated by dividing the system clock by the clock divide factor specified with the BR field. Note: The BR field must only be written when the eQADC SSI is disabled - Refer to EQADC_MCR[ESSIE] field in Section 18.3.2.1, “eQADC Module Configuration Register (EQADC_MCR)” .

0b1101	15
0b1110	16
0b1111	17

¹ If the system clock is divided by an odd number then the serial clock has a duty cycle different from 50%.

18.3.2.13 eQADC SSI Receive Data Register (EQADC_SSIRDR)

The eQADC SSI receive data register (EQADC_SSIRDR) records the last message received from the external device.

Address: Base + 0x0B8

Access: Read

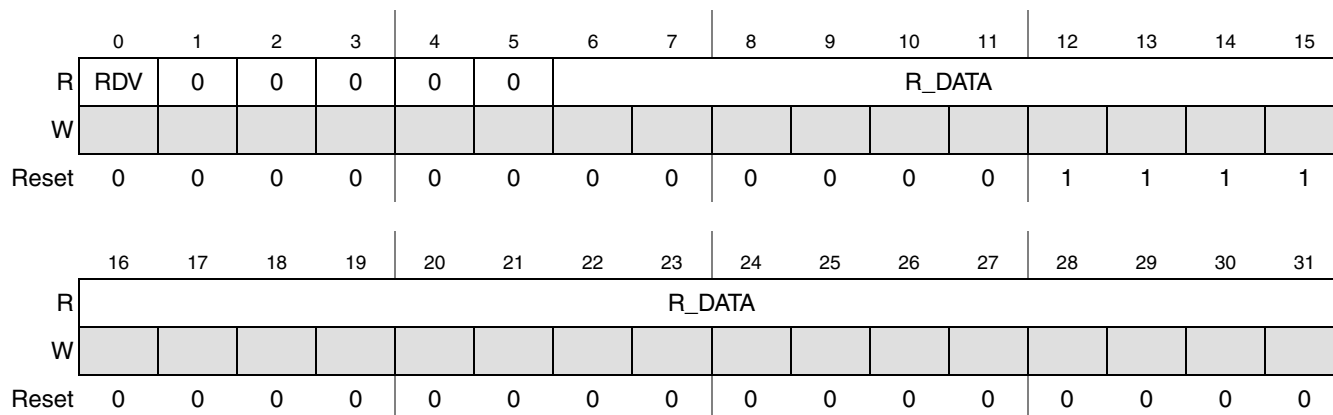

Figure 18-16. eQADC SSI Receive Data Register (EQADC_SSIRDR)

Table 18-22. EQADC_SSIRDR Field Descriptions

Field	Description
0 RDV	Receive data valid. Indicates if the last received data is valid. This bit is cleared automatically whenever the EQADC_SSIRDR is read. Writes have no effect. 0 Receive data is not valid. 1 Receive data is valid.
1–5	Reserved.
6–31 R_DATA [0:25]	eQADC receive DATA. Contains the last result message that was shifted in. Writes to the R_DATA have no effect. Messages that were not completely received due to a transmission abort is not copied into EQADC_SSIRDR.

18.3.2.14 eQADC CFIFO Registers (EQADC_CF[0–5]Rn)

EQADC_CF[0–5]Rn provide visibility of the contents of a CFIFO for debugging purposes. Each CFIFO has four registers that are uniquely mapped to its four 32-bit entries. Refer to [Section 18.4.3, “eQADC Command FIFOs,”](#) for more information on CFIFOs. These registers are read only. Data written to these registers is ignored.

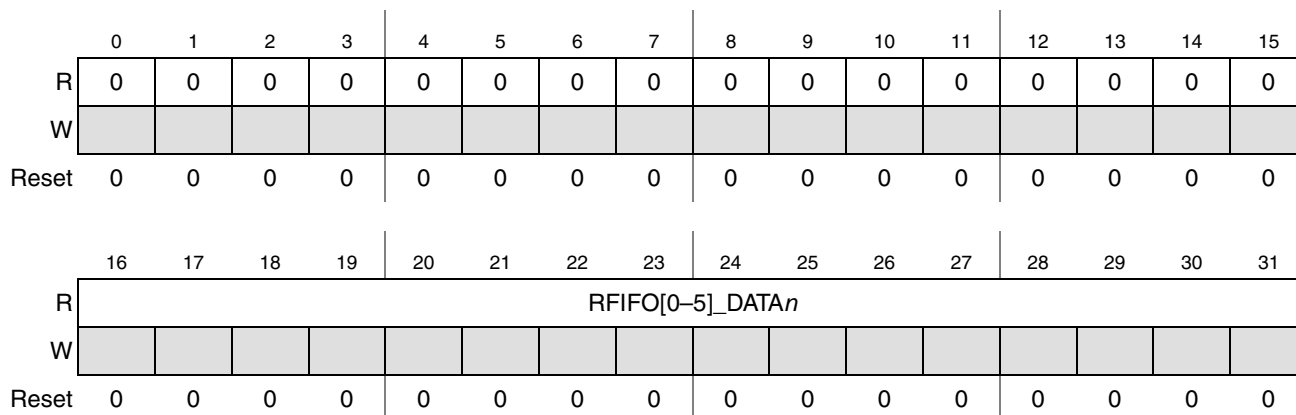

Figure 18-18. eQADC RFIFO_n Registers (EQADC_RF[0–5]R_n)

Table 18-24. EQADC_RF[0–5]R_n Field Descriptions

Field	Description
0–31 RFIFO[0–5] _DATA _n [0:15]	RFIFO[0–5] data <i>n</i> . Returns the value stored within the entry of RFIFO[0–5]. Each RFIFO is composed of four 16-bit entries, with register 0 being mapped to the entry with the smallest memory mapped address.

18.3.3 On-Chip ADC Registers

This section describes a list of registers that control on-chip ADC operation. The ADC registers are not part of the CPU accessible memory map. These registers can only be accessed indirectly through configuration commands. There are five non memory mapped registers per ADC, five for ADC0 and five for ADC1. The address, usage, and access privilege of each register is shown in [Table 18-25](#) and [Table 18-26](#). Data written to or read from reserved areas of the memory map is undefined.

Their assigned addresses are the values used to set the ADC_REG_ADDRESS field of the read/write configuration commands bound for the on-chip ADCs. These are halfword addresses. Further, the following restrictions apply when accessing these registers:

- Registers ADC0_CR, ADC0_GCCR, and ADC0_OCCR can only be accessed by configuration commands sent to the ADC0 command buffer.
- Registers ADC1_CR, ADC1_GCCR, and ADC1_OCCR can only be accessed by configuration commands sent to the ADC1 command buffer.
- Registers ADC_TSCR and ADC_TBCR can be accessed by configuration commands sent to the ADC0 command buffer or to the ADC1 command buffer. A data write to ADC_TSCR through a configuration command sent to the ADC0 command buffer writes the same memory location as when writing to it through a configuration command sent to the ADC1 command buffer. The same is valid for ADC_TBCR.

NOTE

Simultaneous write accesses from the ADC0 and ADC1 command buffers to ADC_TSCR or to ADC_TBCR are not allowed.

Table 18-25. ADC0 Registers

ADC0 Register Address	Use	Access
0x00	ADC0 Address 0x00 is used for conversion command messages.	
0x01	ADC0 Control Register (ADC0_CR)	Write/Read
0x02	ADC Time Stamp Control Register (ADC_TSCR) ¹	Write/Read
0x03	ADC Time Base Counter Register (ADC_TBCR) ¹	Write/Read
0x04	ADC0 Gain Calibration Constant Register (ADC0_GCCR)	Write/Read
0x05	ADC0 Offset Calibration Constant Register (ADC0_OCCR)	Write/Read
0x06–0xFF	Reserved	—

¹ This register is also accessible by configuration commands sent to the ADC1 command buffer.

Table 18-26. ADC1 Registers

ADC1 Register Address	Use	Access
0x00	ADC1 Address 0x00 is used for conversion command messages.	
0x01	ADC1 Control Register (ADC1_CR)	Write/Read
0x02	ADC Time Stamp Control Register (ADC_TSCR) ¹	Write/Read
0x03	ADC Time Base Counter Register (ADC_TBCR) ¹	Write/Read
0x04	ADC1 Gain Calibration Constant Register (ADC1_GCCR)	Write/Read
0x05	ADC1 Offset Calibration Constant Register (ADC1_OCCR)	Write/Read
0x06–0xFF	Reserved	—

¹ This register is also accessible by configuration commands sent to the ADC0 command buffer.

18.3.3.1 ADC_n Control Registers (ADC0_CR and ADC1_CR)

The ADC_n control registers (ADC_n_CR) are used to configure the on-chip ADCs.

Figure 18-19. ADC_n Control Registers (ADC0_CR and ADC1_CR)

Table 18-27. ADC_n_CR Field Descriptions

Field	Description
0 ADC _n _EN	<p>ADC_n enable. Enables ADC_n to perform A/D conversions. Refer to Section 18.4.5.1, “Enabling and Disabling the on-chip ADCs,” for details.</p> <p>0 ADC is disabled. Clock supply to ADC0/1 is stopped.</p> <p>1 ADC is enabled and ready to perform A/D conversions.</p> <p>Note: The bias generator circuit inside the ADC ceases functioning when both ADC0_EN and ADC1_EN bits are negated.</p> <p>Note: Conversion commands sent to a disabled ADC are ignored by the ADC control hardware.</p> <p>Note: When the ADC_n_EN status is changed from asserted to negated, the ADC clock does not stop until it reaches its low phase.</p>
1–3	Reserved.
4 ADC _n _EMUX	<p>ADC_n external multiplexer enable. When ADC_n_EMUX is asserted, the MA pins output digital values to the external channel number selected to convert external multiplexer inputs. Refer to Section 18.4.6, “Internal/External Multiplexing,” for a detailed description about how ADC_n_EMUX affects channel number decoding.</p> <p>0 External multiplexer disabled; no external multiplexer channels can be selected.</p> <p>1 External multiplexer enabled; external multiplexer channels can be selected.</p> <p>Note: Both ADC_n_EMUX bits must not be asserted at the same time.</p> <p>Note: The ADC_n_EMUX bit must only be written when the ADC_n_EN bit is negated. ADC_n_EMUX can be set during the same write cycle used to set ADC_n_EN.</p>
5–10	Reserved.
11–15 ADC _n _CLK_PS [0:4]	<p>ADC_n clock prescaler. The ADC_n_CLK_PS field controls the system clock divide factor for the ADC_n clock as in Table 18-28. Refer to Section 18.4.5.2, “ADC Clock and Conversion Speed,” for details about how to set ADC0/1_CLK_PS.</p> <p>The ADC_n_CLK_PS field must only be written when the ADC_n_EN bit is negated. This field can be configured during the same write cycle used to set ADC_n_EN.</p>

18.3.3.2 ADC Time Stamp Control Register (ADC_TSCR)

The ADC_TSCR contains a system clock divide factor used in the making of the time base counter clock. It determines at what frequency the time base counter runs. ADC_TSCR can be accessed by configuration commands sent to ADC0 or to ADC1. A data write to ADC_TSCR using a configuration command sent to ADC0 writes to the same memory location as a write using a configuration command sent to ADC1.

NOTE

Simultaneous write accesses from ADC0 and ADC1 to ADC_TSCR are not allowed.

Address: 0x02

Access: Read/Write

Figure 18-20. ADC Time Stamp Control Register (ADC_TSCR)

Table 18-29. ADC_TSCR Field Descriptions

Field	Description
0–11	Reserved.
12–15 TBC_CLK_PS [0:3]	Time base counter clock prescaler. Contains the system clock divide factor for the time base counter. It controls the accuracy of the time stamp. The prescaler is disabled when TBC_CLK_PS is set to 0b0000.

Table 18-30. Clock Divide Factor for Time Stamp

TBC_CLK_PS[0:3]	System Clock Divide Factor	Clock to Time Stamp Counter for a 120 MHz System Clock (MHz)
0b0000	Disabled	Disabled
0b0001	1	120
0b0010	2	60
0b0011	4	30
0b0100	6	20

0b0110	10	12
0b0111	12	10
0b1000	16	7.5
0b1001	32	3.75
0b1010	64	1.88
0b1011	128	0.94
0b1100	256	0.47
0b1101	512	0.23
0b1110 - 0b1111	Reserved	—

NOTE

If TBC_CLK_PS is not set to disabled, it must not be changed to any other value besides disabled. If TBC_CLK_PS is set to disabled it can be changed to any other value.

18.3.3.3 ADC Time Base Counter Registers (ADC_TBCR)

The ADC_TBCR contains the current value of the time base counter. ADC_TBCR can be accessed by configuration commands sent to ADC0 or to ADC1. A data write to ADC_TBCR using a configuration command sent to ADC0 writes the same memory location as a write using a configuration command sent to ADC1.

NOTE

Simultaneous write accesses from ADC0 and ADC1 to ADC_TBCR are not allowed.

Figure 18-21. ADC Time Base Counter Register (ADC_TBCR)

Table 18-31. ADC_TBCR Field Descriptions

Field	Description
0–15 TBC_VALUE [0:15]	Time base counter VALUE. Contains the current value of the time base counter. Reading TBC_VALUE returns the current value of time base counter. Writes to TBC_VALUE register load the written data to the counter. The time base counter counts from 0x0000 to 0xFFFF and wraps when reaching 0xFFFF.

18.3.3.4 ADC_n Gain Calibration Constant Registers (ADC0_GCCR and ADC1_GCCR)

The ADC_n_GCCR contains the gain calibration constant used to fine-tune the ADC_n conversion results. Refer to [Section 18.4.5.4, “ADC Calibration Feature,”](#) for details about the calibration scheme used in the eQADC.

Address: 0x04

Access: Read/Write

Figure 18-22. ADCn Gain Calibration Constant Registers (ADCn_GCCR)

Table 18-32. ADCn_GCCR Field Descriptions

Field	Description
0	Reserved.
1–15 GCCn [0:14]	ADCn gain calibration constant. Contains the gain calibration constant used to fine-tune ADCn conversion results. It is a unsigned 15-bit fixed pointed value. The gain calibration constant is an unsigned fixed point number expressed in the <i>GCC_INT.GCC_FRAC</i> binary format. The integer part of the gain constant (GCC_INT) contains a single binary digit while its fractional part (GCC_FRAC) contains 14 digits. For details about the GCC data format refer to Section 18.4.5.4.2, “MAC Unit and Operand Data Format.”

18.3.3.5 ADCn Offset Calibration Constant Registers (ADC0_OCCR and ADC1_OCCR)

The ADCn_OCCR contains the offset calibration constant used to fine-tune of ADC0/1 conversion results. The offset constant is a signed 14-bit integer value. Refer to [Section 18.4.5.4, “ADC Calibration Feature,”](#) for details about the calibration scheme used in the eQADC.

Address: 0x05

Access: Read/Write

Figure 18-23. ADCn Offset Calibration Constant Registers (ADCn_OCCR)

Table 18-33. ADC_n_OCCR Field Descriptions

Field	Description
0–1	Reserved.
2–15 OCC _n [0:13]	ADC _n offset calibration constant. Contains the offset calibration constant used to fine-tune ADC _n conversion results. Negative values should be expressed using the two's complement representation.

18.4 Functional Description

The eQADC provides a parallel interface to two on-chip ADCs, and a single master to single slave serial interface to an off-chip external device. The two on-chip ADCs are architected to allow access to all the analog channels.

Initially, command data is contained in system memory in a user defined data queue structure. Command data is moved between the user-defined queues and CFIFOs by the host CPU or by the eDMA which responds to interrupt and eDMA requests generated by the eQADC. The eQADC supports software and hardware triggers from other modules or external pins to initiate transfers of commands from the multiple CFIFOs to the on-chip ADCs or to the external device.

CFIFOs can be configured to be in single-scan or continuous-scan mode. When a CFIFO is configured to be in single-scan mode, the eQADC scans the user-defined command queue one time. The eQADC stops transferring commands from the triggered CFIFO after detecting the EOQ bit set in the last transfer. After an EOQ bit is detected, software involvement is required to rearm the CFIFO so that it can detect new trigger events.

When a CFIFO is configured for continuous-scan mode, the whole user command queue is scanned multiple times. After the detection of an asserted EOQ bit in the last command transfer, command transfers can continue or not depending on the mode of operation of the CFIFO.

The eQADC can also in parallel and independently of the CFIFOs receive data from the on-chip ADCs or from off-chip external device into multiple RFIFOs. Result data is moved from the RFIFOs to the user-defined result queues in system memory by the host CPU or by the eDMA.

18.4.1 Data Flow in the eQADC

Figure 18-24 shows how command data flows inside the eQADC system. A command message is the predefined format in which command data is stored in the user-defined command queues. A command message has 32 bits and is composed of two parts: a CFIFO header and an ADC command. Command messages are moved from the user command queues to the CFIFOs by the host CPU or by the eDMA as they respond to interrupt and eDMA requests generated by the eQADC. The eQADC generates these requests whenever a CFIFO is not full. The FIFO control unit transfers only the command part of the command message to the ADC. Information in the CFIFO header together with the upper bit of the ADC command is used by the FIFO control unit to arbitrate which triggered CFIFO transfers the next command. Because command transfer through the serial interface can take significantly more time than a parallel transfer to the on-chip ADCs, command transfers for on-chip ADCs occur concurrently with the transfers through the serial interface. Commands sent to the ADCs are executed in a first-in-first-out (FIFO) basis

and three types of results can be expected: data read from an ADC register, a conversion result, or a time stamp. The order at which ADC commands sent to the external device are executed, and the type of results that can be expected depends on the architecture of that device with the exception of unsolicited data like null messages for example.

NOTE

While the eQADC pops commands out from a CFIFO, it also is checking the number of entries in the CFIFO and generating requests to fill it. The process of pushing and popping commands to and from a CFIFO can occur simultaneously.

The FIFO control unit expects all incoming results to be shaped in a pre-defined result message format. [Figure 18-25](#) shows how result data flows inside the eQADC system. Results generated on the on-chip ADCs are formatted into result messages inside the result format and calibration submodule. Results returning from the external device are already formatted into result messages and therefore bypass the result format and calibration submodule located inside the eQADC. A result message is composed of an RFIFO header and an ADC Result. The FIFO control unit decodes the information contained in the RFIFO header to determine the RFIFO to which the ADC result should be sent. After in an RFIFO, the ADC result is moved to the corresponding user result queue by the host CPU or by the eDMA as they respond to interrupt and eDMA requests generated by the eQADC. The eQADC generates these requests whenever an RFIFO has at least one entry.

NOTE

While conversion results are returned, the eQADC is checking the number of entries in the RFIFO and generating requests to empty it. The process of pushing and popping ADC results to and from an RFIFO can occur simultaneously.

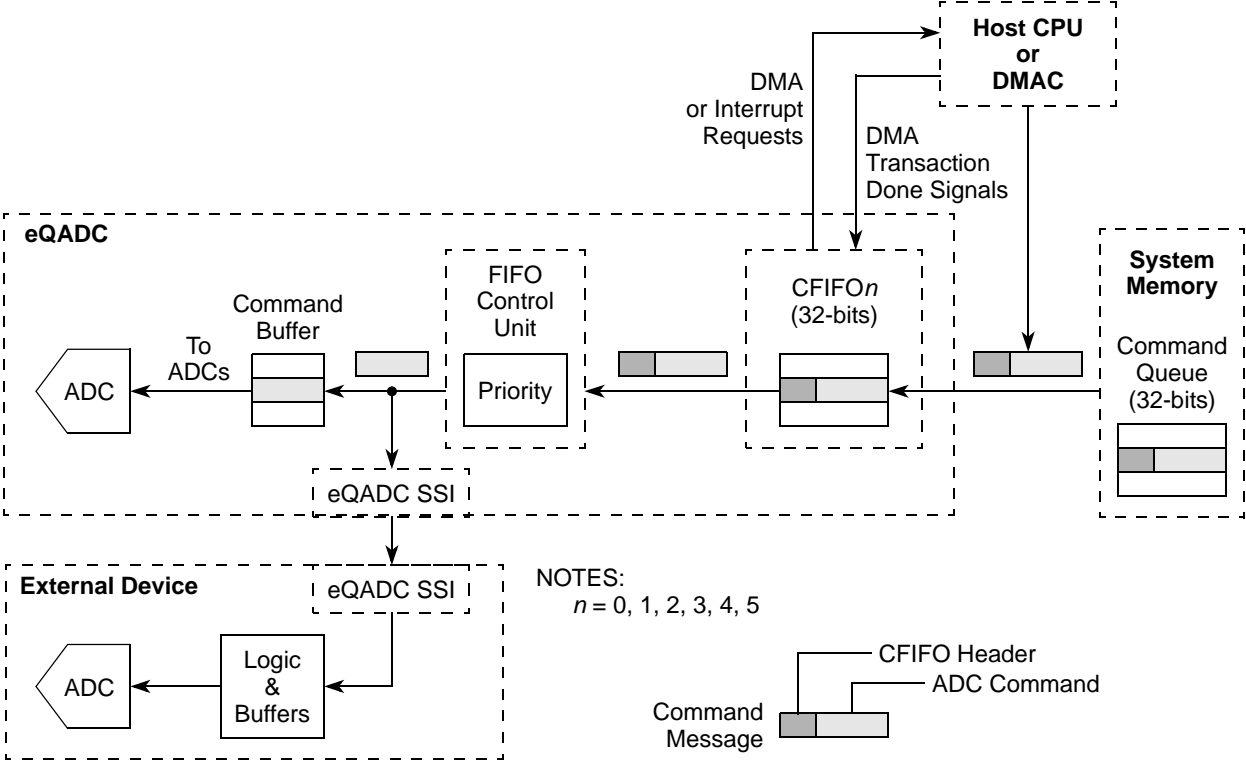

Figure 18-24. Command Flow During eQADC Operation

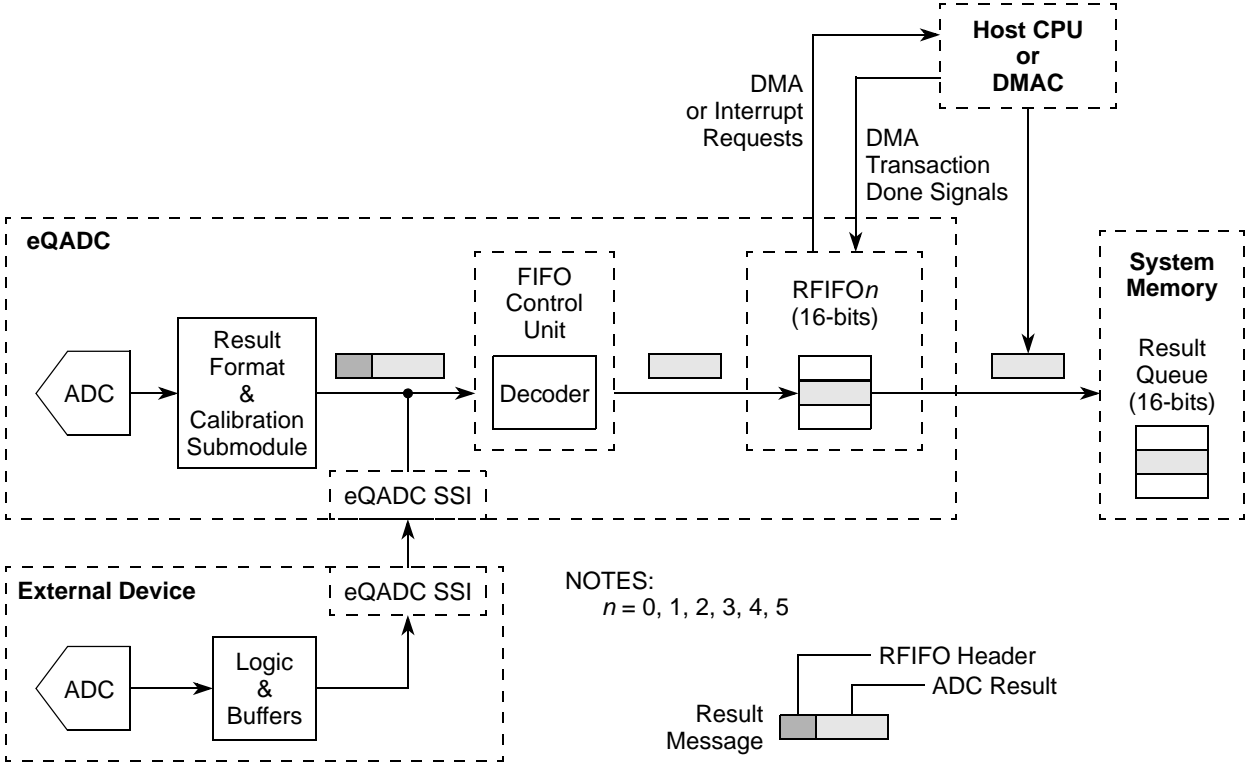

Figure 18-25. Result Flow During eQADC Operation

18.4.1.1 Assumptions/Requirements Regarding the External Device

The external device exchanges command and result data with the eQADC through the eQADC SSI interface. This section explains the minimum requirements an external device has to meet to properly interface with the eQADC. Some assumptions about the architecture of the external device are also described.

18.4.1.1.1 eQADC SSI Protocol Support

The external device must fully support the eQADC SSI protocol as specified in [Section 18.4.8, “eQADC Synchronous Serial Interface \(SSI\) Submodule,”](#) section of this document. Support for the abort feature is optional. When aborts are not supported, all command messages bound for an external command buffer must have the ABORT_ST bit negated - see [Section , “Command Message Format for External Device Operation.”](#)

18.4.1.1.2 Number of Command Buffers and Result Buffers

The external device should have a minimum of one and a maximum of two command buffers to store command data sent from the eQADC. If more than two command buffers are implemented in the external device, they are not recognized by the eQADC as valid destinations for commands. In this document, the two valid external command buffers are referred to as command buffer 2 and command buffer 3 (the two on-chip ADCs being command buffer 0 and 1). The external device decides to which external command buffer a command should go by decoding the upper bit (BN bit) of the ADC command - see [Section , “Command Message Format for External Device Operation.”](#) An external device that only implements one command buffer can ignore the BN bit.

The limit of two command buffers does not limit the number of result buffers in the slave device.

18.4.1.1.3 Command Execution and Result Return

Commands sent to a specific external command buffer should be executed in the order they were received.

Results generated by the execution of commands in an external command buffer should be returned in the order that the command buffer received these commands.

18.4.1.1.4 Null and Result Messages

The external device must be capable of correctly processing null messages as specified in the [Section 18.3.2.2, “eQADC Null Message Send Format Register \(EQADC_NMSFR\).”](#)

In case no valid result data is available to be sent to the eQADC, the external device must send data in the format specified in [Section , “Null Message Format for External Device Operation.”](#)

In case valid result data is available to be sent to the eQADC, the external device must send data in the format specified in [Section , “Result Message Format for External Device Operation.”](#)

The BUSY0/1 fields of all messages sent from the external device to the eQADC must be correctly encoded according to the latest information on the fullness state of the command buffers. For example, if external command buffer 2 is empty before the end of the current serial transmission and if at the end of this transmission the external device receives a command to command buffer 2, then the BUSY0 field, that

is to be sent to the eQADC on the next serial transmission, should be encoded assuming that the external command buffer has one entry.

18.4.1.2 Message Format in eQADC

This section explains the command and result message formats used for on-chip ADC operation and for external device operation.

A command message is the pre-defined format at which command data is stored in the user command queues. A command message has 32 bits and is composed of two parts: a CFIFO header and an ADC command. The size of the CFIFO header is fixed to 6 bits, and it works as inputs to the FIFO control unit. The header controls when a command queue ends, when it pauses, if commands are sent to internal or external buffers, and if it can abort a serial data transmission. Information contained in the CFIFO header, together with the upper bit of the ADC command, is used by the FIFO control unit to arbitrate which triggered CFIFO transfers the next command. ADC commands are encoded inside the least significant 26 bits of the command message.

A result message is composed of an RFIFO header and an ADC result. The FIFO control unit decodes the information contained in the RFIFO header to determine the RFIFO to which the ADC result should be sent. An ADC result is always 16 bits long.

18.4.1.2.1 Message Formats for On-Chip ADC Operation

This section describes the command/result message formats used for on-chip ADC operation.

NOTE

Although this subsection describes how the command and result messages are formatted to communicate with the on-chip ADCs, nothing prevents the programmer from using a different format when communicating with an external device through the serial interface. Refer to [Section 18.4.1.2.2, “Message Formats for External Device Operation.”](#) Apart from the BN bit, the ADC command of a command message can be formatted to communicate to an arbitrary external device provided that the device returns an RFIFO header in the format expected by the eQADC. When the FIFO control unit receives return data message, it decodes the message tag field and stores the 16-bit data into the corresponding RFIFO.

Conversion Command Message Format for On-Chip ADC Operation

[Figure 18-26](#) describes the command message format for conversion commands when interfacing with the on-chip ADCs. A conversion result is always returned for conversion commands and time stamp information can be optionally requested. The lower byte of conversion commands is always set to 0 to distinguish it from configuration commands.

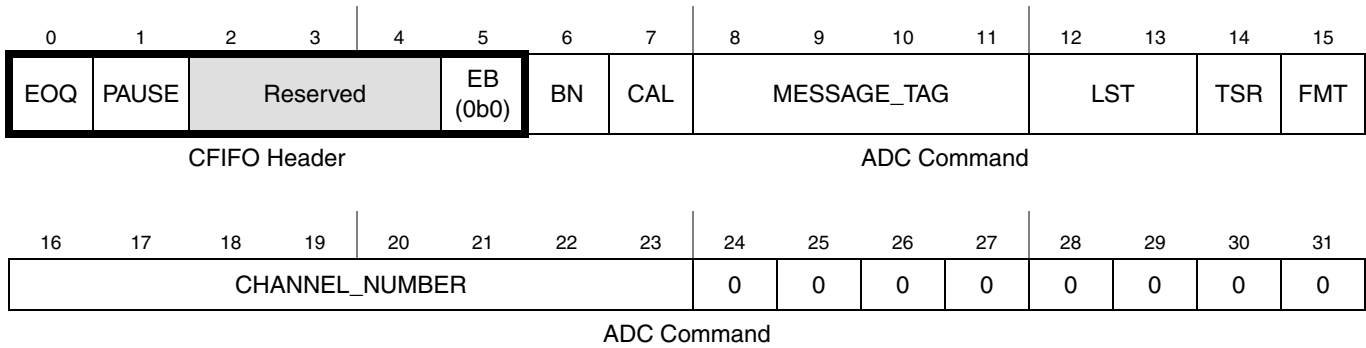

Figure 18-26. Conversion Command Message Format for On-Chip ADC Operation

Table 18-34. On-Chip ADC Field Descriptions: Conversion Command Message Format

Field	Description
0 EOQ	End-of-queue. Asserted in the last command of a command queue to indicate to the eQADC that a scan of the queue is completed. EOQ instructs the eQADC to reset its current CFIFO transfer counter value (TC_CF) to 0. Depending on the CFIFO operating mode, the CFIFO status changes when it detects when the EOQ bit on the last transferred command is asserted. Refer to Section 18.4.3.5, “CFIFO Scan Trigger Modes,” for details. 0 Not the last entry of the command queue. 1 Last entry of the command queue. Note: If both the pause and EOQ bits are asserted in the same command message the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.
1 PAUSE	Pause. Allows software to create sub-queues within a command queue. When the eQADC completes the transfer of a command with an asserted pause bit, the CFIFO enters the WAITING FOR TRIGGER state. Refer to Section 18.4.3.6.1, “CFIFO Operation Status,” for a description of the state transitions. The pause bit is only valid when CFIFO operation mode is configured to single or continuous-scan edge trigger mode. 0 Do not enter WAITING FOR TRIGGER state after transfer of the current command message. 1 Enter WAITING FOR TRIGGER state after transfer of the current command message. Note: If both the pause and EOQ bits are asserted in the same command message the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.
2–4	Reserved.
5 EB	External buffer bit. A negated EB bit indicates that the command is sent to an on chip ADC. 0 Command is sent to an internal buffer. 1 Command is sent to an external buffer.
6 BN	Buffer number. Indicates the ADC to which the message is sent. ADCs 1 and 0 can either be internal or external depending on the EB bit setting. 0 Message sent to ADC 0. 1 Message sent to ADC 1.
7 CAL	Calibration. Indicates if the returning conversion result must be calibrated. 0 Do not calibrate conversion result. 1 Calibrate conversion result.

Table 18-34. On-Chip ADC Field Descriptions: Conversion Command Message Format (continued)

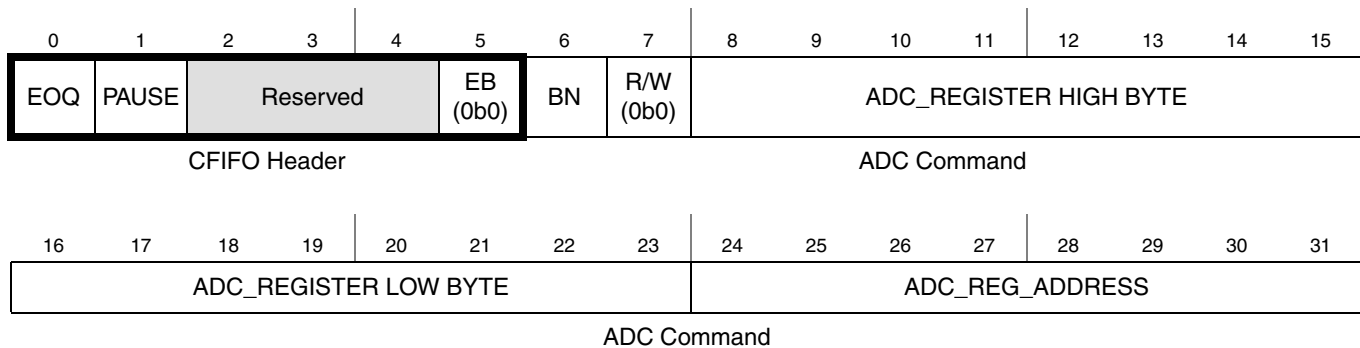

Field	Description																								
8–11 MESSAGE_TAG [0:3]	<p>MESSAGE_TAG field. Allows the eQADC to separate returning results into different RFIFOs. When the eQADC transfers a command, the MESSAGE_TAG is included as part of the command. Eventually the external device/on-chip ADC returns the result with the same MESSAGE_TAG. The eQADC separates incoming messages into different RFIFOs by decoding the MESSAGE_TAG of the incoming data.</p> <table border="1"> <thead> <tr> <th>MESSAGE_TAG[0:3]</th> <th>MESSAGE_TAG Meaning</th> </tr> </thead> <tbody> <tr> <td>0b0000</td> <td>Result is sent to RFIFO 0</td> </tr> <tr> <td>0b0001</td> <td>Result is sent to RFIFO 1</td> </tr> <tr> <td>0b0010</td> <td>Result is sent to RFIFO 2</td> </tr> <tr> <td>0b0011</td> <td>Result is sent to RFIFO 3</td> </tr> <tr> <td>0b0100</td> <td>Result is sent to RFIFO 4</td> </tr> <tr> <td>0b0101</td> <td>Result is sent to RFIFO 5</td> </tr> <tr> <td>0b0110–0b0111</td> <td>Reserved</td> </tr> <tr> <td>0b1000</td> <td>Null message received</td> </tr> <tr> <td>0b1001</td> <td>Reserved for customer use.¹</td> </tr> <tr> <td>0b1010</td> <td>Reserved for customer use.¹</td> </tr> <tr> <td>0b1011–0b1111</td> <td>Reserved</td> </tr> </tbody> </table> <p>¹ These messages are treated as null messages. Therefore, they must obey the format for incoming null messages and return valid BUSY0/1 fields. 14 TSR	<p>Time stamp request. TSR indicates the request for a time stamp. When TSR is asserted, the on-chip ADC control logic returns a time stamp for the current conversion command after the conversion result is sent to the RFIFOs. Refer to Section 18.4.5.3, “Time Stamp Feature,” for details.</p> <p>0 Return conversion result only. 1 Return conversion time stamp after the conversion result.</p>																								
15 FMT	<p>Conversion data format. FMT specifies to the eQADC how to format the 12-bit conversion data returned by the ADCs into the 16-bit format which is sent to the RFIFOs. Refer to Section , “ADC Result Format for On-Chip ADC Operation,” for details.</p> <p>0 Right justified unsigned. 1 Right justified signed.</p>																								

Table 18-34. On-Chip ADC Field Descriptions: Conversion Command Message Format (continued)

Field	Description
16–23 CHANNEL_NUMBER [0:7]	Channel number. Selects the analog input channel. The software programs this field with the channel number corresponding to the analog input pin to be sampled and converted. Refer to Section 18.4.6.1, “Channel Assignment,” for details.
24–31	Reserved.

Write Configuration Command Message Format for On-Chip ADC Operation

Figure 18-27 describes the command message format for a write configuration command when interfacing with the on-chip ADCs. A write configuration command is used to set the control registers of the on-chip ADCs. No conversion data is returned for a write configuration command. Write configuration commands are differentiated from read configuration commands by a negated R/W bit.

Figure 18-27. Write Configuration Command Message Format for On-chip ADC Operation
Table 18-35. On-Chip ADC Field Descriptions: Write Configuration

Field	Description
0 EOQ	End-of-queue. Asserted in the last command of a command queue to indicate to the eQADC that a scan of the queue is completed. EOQ instructs the eQADC to reset its current CFIFO transfer counter value (TC_CF) to 0. Depending on the CFIFO mode of operation, the CFIFO status also changes upon the detection of an asserted EOQ bit on the last transferred command. Refer to Section 18.4.3.5, “CFIFO Scan Trigger Modes,” for details. 0 Not the last entry of the command queue. 1 Last entry of the command queue. Note: If both the pause and EOQ bits are asserted in the same command message the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.
1 PAUSE	Pause bit. Allows software to create sub-queues within a command queue. When the eQADC completes the transfer of a command with an asserted pause bit, the CFIFO enters the WAITING FOR TRIGGER state. Refer to Section 18.4.3.6.1, “CFIFO Operation Status,” for a description of the state transitions. The pause bit is only valid when CFIFO operation mode is configured to single or continuous-scan edge trigger mode. 0 Do not enter WAITING FOR TRIGGER state after transfer of the current command message. 1 Enter WAITING FOR TRIGGER state after transfer of the current command message. Note: If both the pause and EOQ bits are asserted in the same command message, the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.
2–4	Reserved.

Table 18-35. On-Chip ADC Field Descriptions: Write Configuration

Field	Description
5 EB	External buffer bit. This bit should always be cleared for messages sent to an on-chip ADC. 0 Command is sent to an internal command buffer. 1 Command is sent to an external command buffer.
6 BN	Buffer number. Indicates in which buffer the message is stored. Buffers 1 and 0 can either be internal or external depending on the EB bit setting. 0 Message stored in buffer 0. 1 Message stored in buffer 1.
7 R/W	Read/write. A negated R/W indicates a write configuration command. 0 Write 1 Read
8–15 ADC_ REGISTER _HIGH_ BYTE[0:7]	ADC register high byte. The value to be written into the most significant 8 bits of control/configuration register when the R/W bit is negated.
16–23 ADC_ REGISTER _LOW_ BYTE[0:7]	ADC register low byte. The value to be written into the least significant 8 bits of a control/configuration register when the R/W bit is negated.
24–31 ADC_REG_ ADDRESS [0:7]	ADC register address. Selects a register on the ADC register set to be written or read. Only halfword addresses can be used. Refer to Table 18-25 .

Read Configuration Command Message Format for On-Chip ADC Operation

Figure 18-28 describes the command message format for a read configuration command when interfacing with the on-chip ADCs. A read configuration command is used to read the contents of the on-chip ADC registers which are only accessible via command messages. Read configuration commands are differentiated from write configuration commands by an asserted R/W bit.

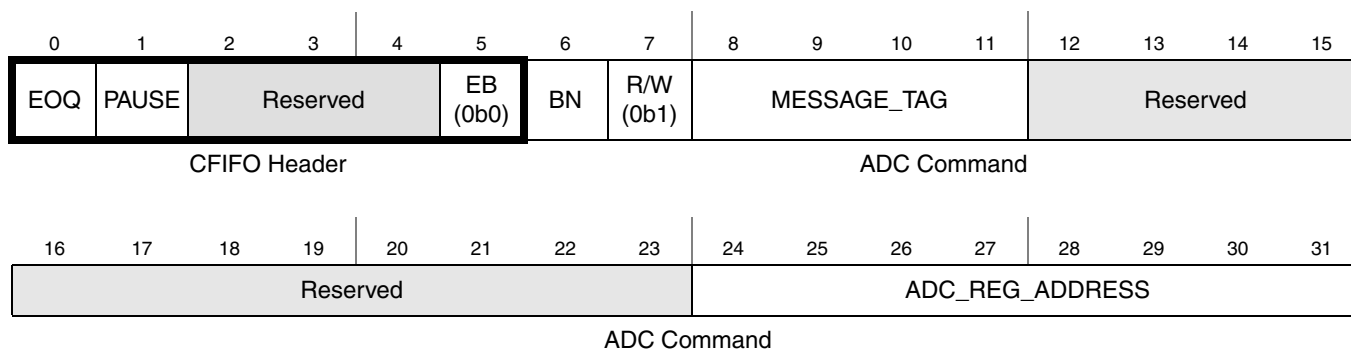

Figure 18-28. Read Configuration Command Message Format for On-Chip ADC Operation

Table 18-36. On-Chip ADC Field Descriptions: Read Configuration

Field	Description
0 EOQ	<p>End-of-queue. Asserted in the last command of a command queue to indicate to the eQADC that a scan of the queue is completed. EOQ instructs the eQADC to reset its current CFIFO transfer counter value (TC_CF) to 0. Depending on the CFIFO mode of operation, the CFIFO status changes upon the detection of an asserted EOQ bit on the last transferred command. Refer to Section 18.4.3.5, “CFIFO Scan Trigger Modes,” for details.</p> <p>0 Not the last entry of the command queue. 1 Last entry of the command queue.</p> <p>Note: If both the pause and EOQ bits are asserted in the same command message the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.</p>
1 PAUSE	<p>Pause bit. Allows software to create sub-queues within a command queue. When the eQADC completes the transfer of a command with an asserted pause bit, the CFIFO enters the WAITING FOR TRIGGER state. Refer to Section 18.4.3.6.1, “CFIFO Operation Status,” for a description of the state transitions. The pause bit is only valid when CFIFO operation mode is configured to single or continuous-scan edge trigger mode.</p> <p>0 Do not enter WAITING FOR TRIGGER state after transfer of the current command message. 1 Enter WAITING FOR TRIGGER state after transfer of the current command message.</p> <p>Note: If both the pause and EOQ bits are asserted in the same command message the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.</p>
2–4	Reserved.
5 EB	<p>External buffer bit. This bit should always be cleared for messages sent to an on-chip ADC.</p> <p>0 Command is sent to an internal command buffer. 1 Command is sent to an external command buffer.</p>
6 BN	<p>Buffer number. Indicates in which buffer the message is stored. Buffers 1 and 0 can either be internal or external depending on the EB bit setting.</p> <p>0 Message stored in buffer 0. 1 Message stored in buffer 1.</p>
7 R/W	<p>Read/write. An asserted R/W bit indicates a read configuration command.</p> <p>0 Write 1 Read</p>

Table 18-36. On-Chip ADC Field Descriptions: Read Configuration (continued)

Field	Description																								
8–11 MESSAGE_TAG[0:3]	<p>MESSAGE_TAG field. Allows the eQADC to separate returning results into different RFIFOs. When the eQADC transfers a command, the MESSAGE_TAG is included as part of the command. Eventually the external device/on-chip ADC returns the result with the same MESSAGE_TAG. The eQADC separates incoming messages into different RFIFOs by decoding the MESSAGE_TAG of the incoming data.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>MESSAGE_TAG[0:3]</th> <th>MESSAGE_TAG Meaning</th> </tr> </thead> <tbody> <tr> <td>0b0000</td> <td>Result is sent to RFIFO 0</td> </tr> <tr> <td>0b0001</td> <td>Result is sent to RFIFO 1</td> </tr> <tr> <td>0b0010</td> <td>Result is sent to RFIFO 2</td> </tr> <tr> <td>0b0011</td> <td>Result is sent to RFIFO 3</td> </tr> <tr> <td>0b0100</td> <td>Result is sent to RFIFO 4</td> </tr> <tr> <td>0b0101</td> <td>Result is sent to RFIFO 5</td> </tr> <tr> <td>0b0110–0b0111</td> <td>Reserved</td> </tr> <tr> <td>0b1000</td> <td>Null message received</td> </tr> <tr> <td>0b1001</td> <td>Reserved for customer use. ¹</td> </tr> <tr> <td>0b1010</td> <td>Reserved for customer use. ¹</td> </tr> <tr> <td>0b1011–0b1111</td> <td>Reserved</td> </tr> </tbody> </table> <p>¹ These messages are treated as null messages. ADC Result Format for On-Chip ADC Operation

When the FIFO control unit receives a return data message, it decodes the MESSAGE_TAG field and stores the 16-bit data into the appropriate RFIFO. This section describes the ADC result portion of the result message returned by the on-chip ADCs.

The 16-bit data stored in the RFIFOs can be the following:

- Data read from an ADC register with a read configuration command. In this case, the stored 16-bit data corresponds to the contents of the ADC register that was read.
- A time stamp. In this case, the stored 16-bit data is the value of the time base counter latched when the eQADC detects the end of the analog input voltage sampling. For details see [Section 18.4.5.3, “Time Stamp Feature.”](#)
- A conversion result. In this case, the stored 16-bit data contains a right justified 14-bit result data. The conversion result can be calibrated or not depending on the status of CAL bit in the command that requested the conversion. When the CAL bit is negated, this 14-bit data is obtained by executing a 2-bit left-shift on the 12-bit data received from the ADC. When the CAL bit is asserted,

this 14-bit data is the result of the calculations performed in the EQADC MAC unit using the 12-bit data received from the ADC and the calibration constants GCC and OCC (Refer to [Section 18.4.5.4, “ADC Calibration Feature”](#)). Then, this 14-bit data is further formatted into a 16-bit format according to the status of the FMT bit in the conversion command. When FMT is asserted, the 14-bit result data is reformatted to look as if it was measured against an imaginary ground at VREF/2 (the msb (most significant bit) bit of the 14-bit result is inverted), and is sign-extended to a 16-bit format as in [Figure 18-29](#). When FMT is negated, the eQADC zero-extends the 14-bit result data to a 16-bit format as in [Figure 18-30](#). Correspondence between the analog voltage in a channel and the calculated digital values is shown in [Table 18-39](#).

Figure 18-29. ADC Result Format when FMT = 1 (Right Justified Signed)—On-Chip ADC Operation

Table 18-37. ADC Result Format when FMT = 1 Field Descriptions

Field	Description
0–1 SIGN_EXT[0:1]	Sign extension. Only has meaning when FMT is asserted. SIGN_EXT is 0b00 when CONVERSION_RESULT is positive, and 0b11 when CONVERSION_RESULT is negative.
2–15 CONVERSION_RESULT [0:13]	Conversion result. A digital value corresponding to the analog input voltage in a channel when the conversion command was initiated. The two’s complement representation is used to express negative values.

Figure 18-30. ADC Result Format when FMT = 0 (Right Justified Unsigned)—On-Chip ADC Operation

Table 18-38. ADC Result Format when FMT = 0 Field Descriptions

Field	Description
0–1 SIGN_EXT[0:1]	Sign extension. Only has meaning when FMT is asserted. SIGN_EXT is 0b00 when CONVERSION_RESULT is positive, and 0b11 when CONVERSION_RESULT is negative.
2–15 CONVERSION_RESULT [0:13]	Conversion result. A digital value corresponding to the analog input voltage in a channel when the conversion command was initiated.

Table 18-39. Correspondence between Analog Voltages and Digital Values^{1, 2}

	Voltage Level on Channel (V)	Corresponding 12-bit Conversion Result Returned by the ADC	16-bit Result Sent to RFIFOs (FMT=0) ³	16-bit Result Sent to RFIFOs (FMT=1) ³
Single-Ended Conversions	5.12	0xFFF	0x3FFC	0x1FFC
	5.12 – 1sb	0xFFF	0x3FFC	0x1FFC

	2.56	0x800	0x2000	0x0000

	1 1sb	0x001	0x0004	0xE004
	0	0x000	0x0000	0xE000
Differential Conversions	2.56	0xFFF	0x3FFC	0x1FFC
	2.56 – 1sb	0xFFF	0x3FFC	0x1FFC

	0	0x800	0x2000	0x0000

	-2.56 + 1sb	0x001	0x0004	0xE004
	-2.56	0x000	0x0000	0xE000

¹ $V_{REF}=V_{RH} -V_{RL}=5.12V$. Resulting in one 12-bit count (1sb) =1.25mV.
² The two’s complement representation is used to express negative values.
³ Assuming uncalibrated conversion results.

18.4.1.2.2 Message Formats for External Device Operation

This section describes the command messages, data messages, and null messages formats used for external device operation.

Command Message Format for External Device Operation

Figure 18-31 describes the command message format for external device operation. Command message formats for on-chip operation and for external device operation share the same CFIFO header format. However, there are no limitations regarding the format an ADC Command used to communicate to an arbitrary external device. Only the upper bit of an ADC Command has a fixed format (BN field) to indicate to the FIFO control unit/external device to which external command buffer the corresponding command should be sent. The remaining 25 bits can be anything decodable by the external device. Only the ADC command portion of a command message is transferred to the external device.

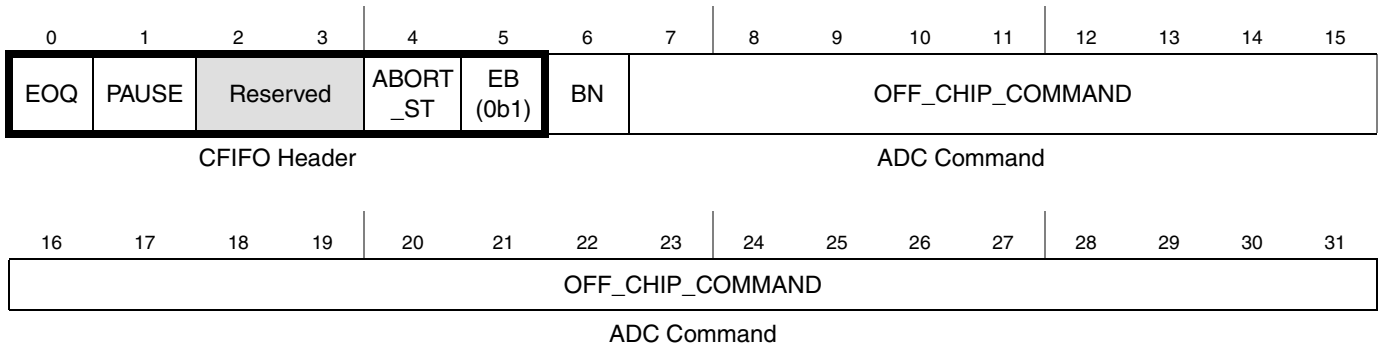

Figure 18-31. Command Message Format for External Device Operation

Table 18-40. On-Chip ADC Field Descriptions: External Device Operation

Field	Description
0 EOQ	End-of-queue. Asserted in the last command of a command queue to indicate to the eQADC that a scan of the queue is completed. EOQ instructs the eQADC to reset its current CFIFO transfer counter value (TC_CF) to 0. Depending on the CFIFO mode of operation, the CFIFO status changes upon the detection of an asserted EOQ bit on the last transferred command. Refer to Section 18.4.3.5, “CFIFO Scan Trigger Modes,” for details. 0 Not the last entry of the command queue. 1 Last entry of the command queue. Note: If both the pause and EOQ bits are asserted in the same command message the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.
1 PAUSE	Pause bit. Allows software to create sub-queues within a command queue. When the eQADC completes the transfer of a command with an asserted pause bit, the CFIFO enters the WAITING FOR TRIGGER state. Refer to Section 18.4.3.6.1, “CFIFO Operation Status,” for a description of the state transitions. The pause bit is only valid when CFIFO operation mode is configured to single or continuous-scan edge trigger mode. 0 Do not enter WAITING FOR TRIGGER state after transfer of the current command message. 1 Enter WAITING FOR TRIGGER state after transfer of the current command message. Note: If both the pause and EOQ bits are asserted in the same command message the respective flags are set, but the CFIFO status changes as if only the EOQ bit were asserted.
2–3	Reserved.
4 ABORT_ST	ABORT serial transmission. Indicates whether an on-going serial transmission should be aborted or not. All CFIFOs can abort null message transmissions when triggered but only CFIFO0 can abort command transmissions of lower priority CFIFOs. For more on serial transmission aborts see Section 18.4.3.2, “CFIFO Prioritization and Command Transfer.” 0 Do not abort current serial transmission. 1 Abort current serial transmission.
5 EB	External buffer. This bit should always be set for messages sent to an external ADC. 0 Command is sent to an internal command buffer. 1 Command is sent to an external command buffer.
6 BN	Refer to Section , “Conversion Command Message Format for On-Chip ADC Operation.”
7–31 OFF_CHIP_COMMAND [0:24]	OFF-CHIP COMMAND Field. The OFF_CHIP_COMMAND field can be anything decodable by the external device. It is 25 bits long and it is transferred together with the BN bit to the external device when the CFIFO is triggered. Refer to Section , “Conversion Command Message Format for On-Chip ADC Operation,” for a description of the command message used when interfacing with the on-chip ADCs.

Result Message Format for External Device Operation

Data is returned from the ADCs in the form of result messages. A result message is composed of an RFIFO header and an ADC result. The FIFO control unit decodes the information contained in the RFIFO header and sends the contents of the ADC result to the appropriate RFIFO. Only data stored on the ADC_RESULT field is stored in the RFIFOs/result queues. The ADC result of any received message with a null data message tag is ignored. The format of a result message returned from the external device is shown in Figure 18-32. It is 26 bits long, and is composed of a MESSAGE_TAG field, information about the status of the buffers (BUSY fields), and result data. The BUSY fields are needed to inform the eQADC about when it is appropriate to transfer commands to the external command buffers.

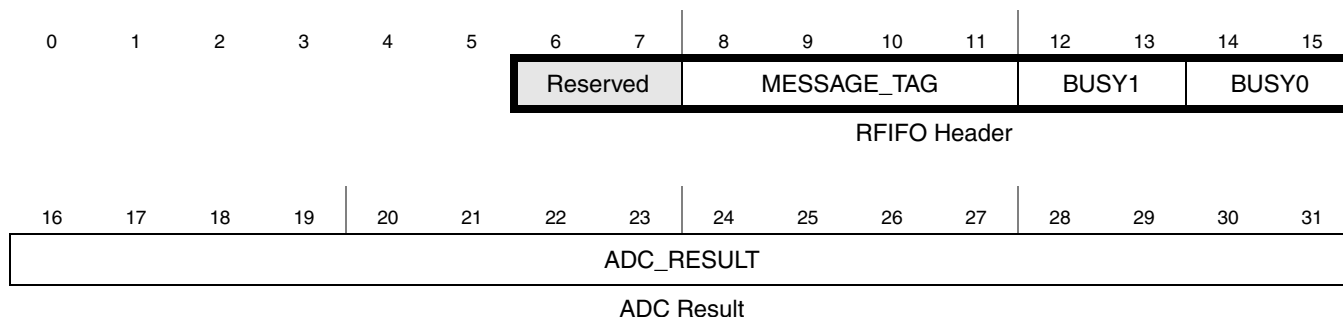

Figure 18-32. Result Message Format for External Device Operation

Table 18-41. Result Message Format for External Device Operation

Field	Description
6–7	Reserved.
8–11 MESSAGE_TAG[0:3]	MESSAGE_TAG Field. Refer to Section , “Conversion Command Message Format for On-Chip ADC Operation.”
12–15 BUSY _n [0:1]	BUSY status. The BUSY fields indicate if the external device can receive more commands. Table 18-42 shows how these two bits are encoded. When an external device cannot accept any more new commands, it must set BUSY _n to a value indicating “Do not send commands” in the returning message. The BUSY fields of values 0b10 and 0b10 can be freely encoded by the external device to allow visibility of the status of the external command buffers for debug. As an example, they could indicate the number of entries in an external command buffer.
16–31 ADC_RESULT [0:15]	ADC RESULT Field. The result data received from the external device or on-chip ADC. This can be the result of a conversion command, data requested via a read configuration command, or time stamp value. The ADC_RESULT of any incoming message with a null message tag is ignored. When the MESSAGE_TAG is for an RFIFO, the eQADC extracts the 16-bit ADC_RESULT from the raw message and stores it into the appropriate RFIFO.

Table 18-42. Command $BUSY_n$ BUSY Status¹

BUSY _n [0:1]	Meaning
0b00	Send available commands—command buffer is empty
0b01	Send available commands
0b10	Send available commands
0b11	Do not send commands

¹ After reset, the eQADC always assumes that the external command buffers are full and cannot receive commands.

Null Message Format for External Device Operation

Null messages are only transferred through the serial interface to allow results and unsolicited control data, like the status of the external command buffers, to return when there are no more commands pending to transfer. Null messages are only transmitted when serial transmissions from the eQADC SSI are enabled (see ESSIE field in Section 18.3.2.1, “eQADC Module Configuration Register (EQADC_MCR),”), and when one of the following conditions apply:

1. There are no triggered CFIFOs with commands bound for external command buffers.
2. There are triggered CFIFOs with commands bound for external command buffers but the external buffers are full. The eQADC detected returning BUSY_n fields indicating “Do not send commands.”

Figure 18-33 illustrates the null message send format. When the eQADC transfers a null message, it directly shifts out the 26-bit data content inside the Section 18.3.2.2, “eQADC Null Message Send Format Register (EQADC_NMSFR).” The register must be programmed with the null message send format of the external device.

Figure 18-34 illustrates the null message receive format. It has the same fields found in a result message with the exception that the ADC result is not used. Refer to Section , “Result Message Format for External Device Operation,” for more information. The MESSAGE_TAG field must be set to the null message tag (0b1000). The eQADC does not store into an RFIFO any incoming message with a null message tag.

Figure 18-33. Null Message Send Format for External Device Operation

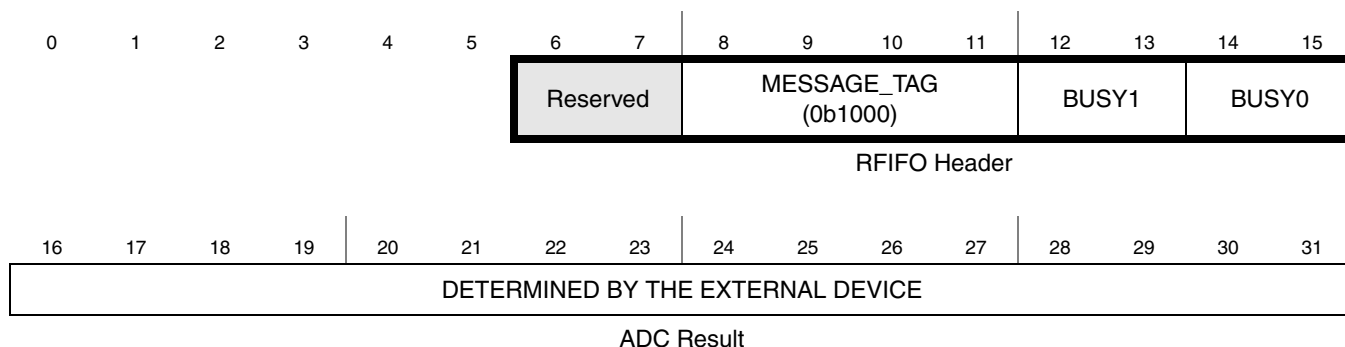

Figure 18-34. Null Message Receive Format for External Device Operation

Table 18-43. Null Message Receive Format for External Device Operation

Field	Description
6–7	Reserved.
8–11 MESSAGE_TAG[0:3]	MESSAGE_TAG field. Refer to Section , “ Conversion Command Message Format for On-Chip ADC Operation. ”
12–15 BUSY _n [0:1]	BUSY status. Refer to Section , “ Result Message Format for External Device Operation. ”
16–31	Determined by the external device.

18.4.2 Command/Result Queues

The command and result queues are actually part of the eQADC system although they are not hardware implemented inside the eQADC. Instead command and result queues are user-defined queues located in system memory. Each command queue entry is a 32-bit command message. The last entry of a command queue has the EOQ bit asserted to indicate that it is the last entry of the queue. The result queue entry is a 16-bit data item.

Refer to [Section 18.1.4, “Modes of Operation,”](#) for a description of the message formats and their flow in eQADC.

Refer to [Section 18.5.5, “Command Queue and Result Queue Usage,”](#) for examples of how command queues and result queues can be used.

18.4.3 eQADC Command FIFOs

18.4.3.1 CFIFO Basic Functionality

There are six prioritized CFIFOs located in the eQADC. Each CFIFO is four entries deep, and each CFIFO entry is 32 bits long. A CFIFO serves as a temporary storage location for the command messages stored in the command queues in system memory. When a CFIFO is not full, the eQADC sets the corresponding CFFF bit in [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISR_n\).”](#) If

CFFE is asserted as in [Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 \(EQADC_IDCRn\),”](#) the eQADC generates requests for more commands from a command queue. An interrupt request, served by the host CPU, is generated when CFFS is negated, and a eDMA request, served by the eDMA, is generated when CFFS is asserted. The host CPU or the eDMA respond to these requests by writing to the [Section 18.3.2.4, “eQADC CFIFO Push Registers 0–5 \(EQADC_CFPRn\),”](#) to fill the CFIFO.

NOTE

Only whole words must be written to EQADC_CFPR. Writing halfwords or bytes to EQADC_CFPR pushes the entire 32-bit CF_PUSH field into the corresponding CFIFO, but undefined data fills the areas of CF_PUSH that were not specifically designated as target locations for writing.

[Figure 18-35](#) describes the important components in the CFIFO. Each CFIFO is implemented as a circular set of registers to avoid the need to move all entries at each push/pop operation. The push next data pointer points to the next available CFIFO location for storing data written into the eQADC command FIFO push register. The transfer next data pointer points to the next entry to be removed from CFIFO_n when it completes a transfer. The CFIFO transfer counter control logic counts the number of entries in the CFIFO and generates eDMA or interrupt requests to fill the CFIFO. TNXTPTR in [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\),”](#) indicates the index of the entry that is currently being addressed by the transfer next data pointer, and CFCTR, in the same register, provides the number of entries stored in the CFIFO.

Using TNXTPTR and CFCTR, the absolute addresses for the entries indicated by the transfer next data pointer and by the push next data pointer can be calculated using the following formulas:

$$\begin{aligned} \text{Transfer Next Data Pointer Address} &= \text{CFIFO}_n\text{_BASE_ADDRESS} + \text{TNXTPTR}_n * 4 \\ \text{Push Next Data Pointer Address} &= \text{CFIFO}_n\text{_BASE_ADDRESS} + \\ &[(\text{TNXTPTR}_n + \text{CFCTR}_n) \bmod \text{CFIFO_DEPTH}] * 4 \end{aligned}$$

where

- $a \bmod b$ returns the remainder of the division of a by b .
- CFIFO_n_BASE_ADDRESS is the smallest memory mapped address allocated to a CFIFO_n entry.
- CFIFO_DEPTH is the number of entries contained in a CFIFO - four in this implementation.

When CFS_n in [Section 18.3.2.11, “eQADC CFIFO Status Register \(EQADC_CFSR\),”](#) is in the TRIGGERED state, the eQADC generates the proper control signals for the transfer of the entry pointed by transfer next data pointer. CFUF_n in [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\),”](#) is set when a CFIFO_n underflow event occurs. A CFIFO underflow occurs when the CFIFO is in the TRIGGERED state and it becomes empty. No commands are transferred from an underflowing CFIFO, and command transfers from lower priority CFIFOs are not blocked. CFIFO_n is empty when the transfer next data pointer n equals the push next data pointer n and CFCTR_n is 0. CFIFO_n is full when the transfer next data pointer n equals the push next data pointer n and CFCTR_n is not 0.

When the eQADC completes the transfer of an entry from CFIFO_n: the transferred entry is popped from CFIFO_n, the CFIFO counter CFCTR in the [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\),”](#) is decremented by 1, and transfer next data pointer n is incremented by 1 (or wrapped around) to point to the next entry in the CFIFO. The transfer of entries bound for the on-chip

ADCs is considered completed when they are stored in the appropriate ADC command buffer. The transfer of entries bound for the external device is considered completed when the serial transmission of the entry is completed.

When the EQADC_CFPR n is written and CFIFO n is not full, the CFIFO counter CFCTR n is incremented by 1, and the push next data pointer n then is incremented by 1 (or wrapped around) to point to the next entry in the CFIFO.

When the EQADC_CFPR n is written but CFIFO n is full, the eQADC does not increment the counter value and does not overwrite any entry in CFIFO n .

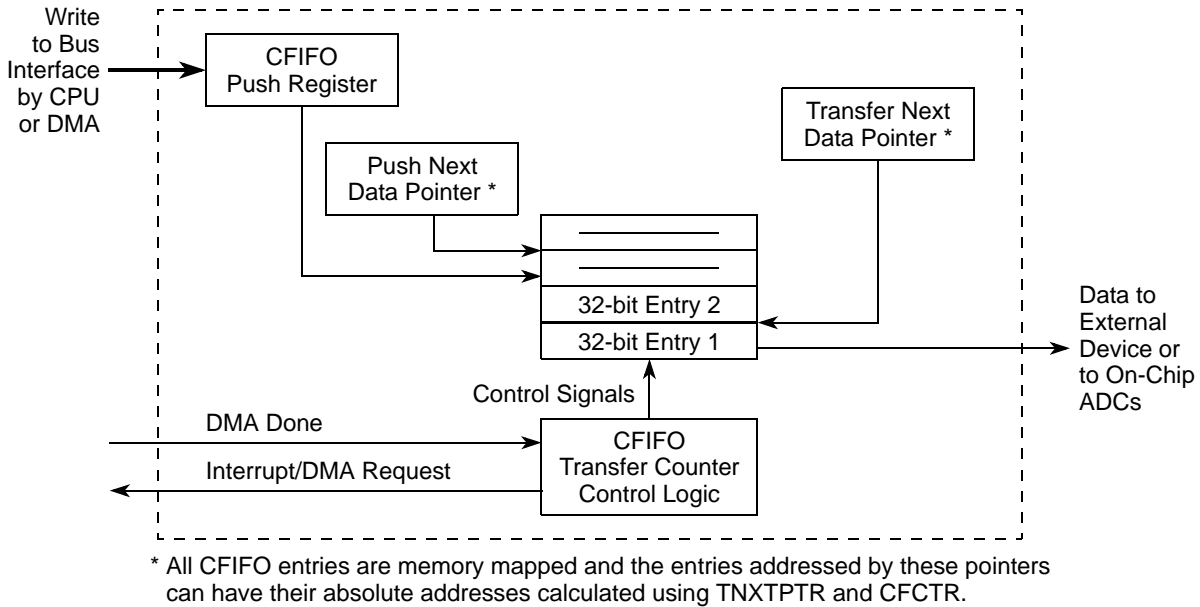

Figure 18-35. CFIFO Diagram

The detailed behavior of the push next data pointer and transfer next data pointer is described in the example shown in [Figure 18-36](#) where a CFIFO with 16 entries is shown for clarity of explanation, the actual hardware implementation has only four entries. In this example, CFIFO n with 16 entries is shown in sequence after pushing and transferring entries.

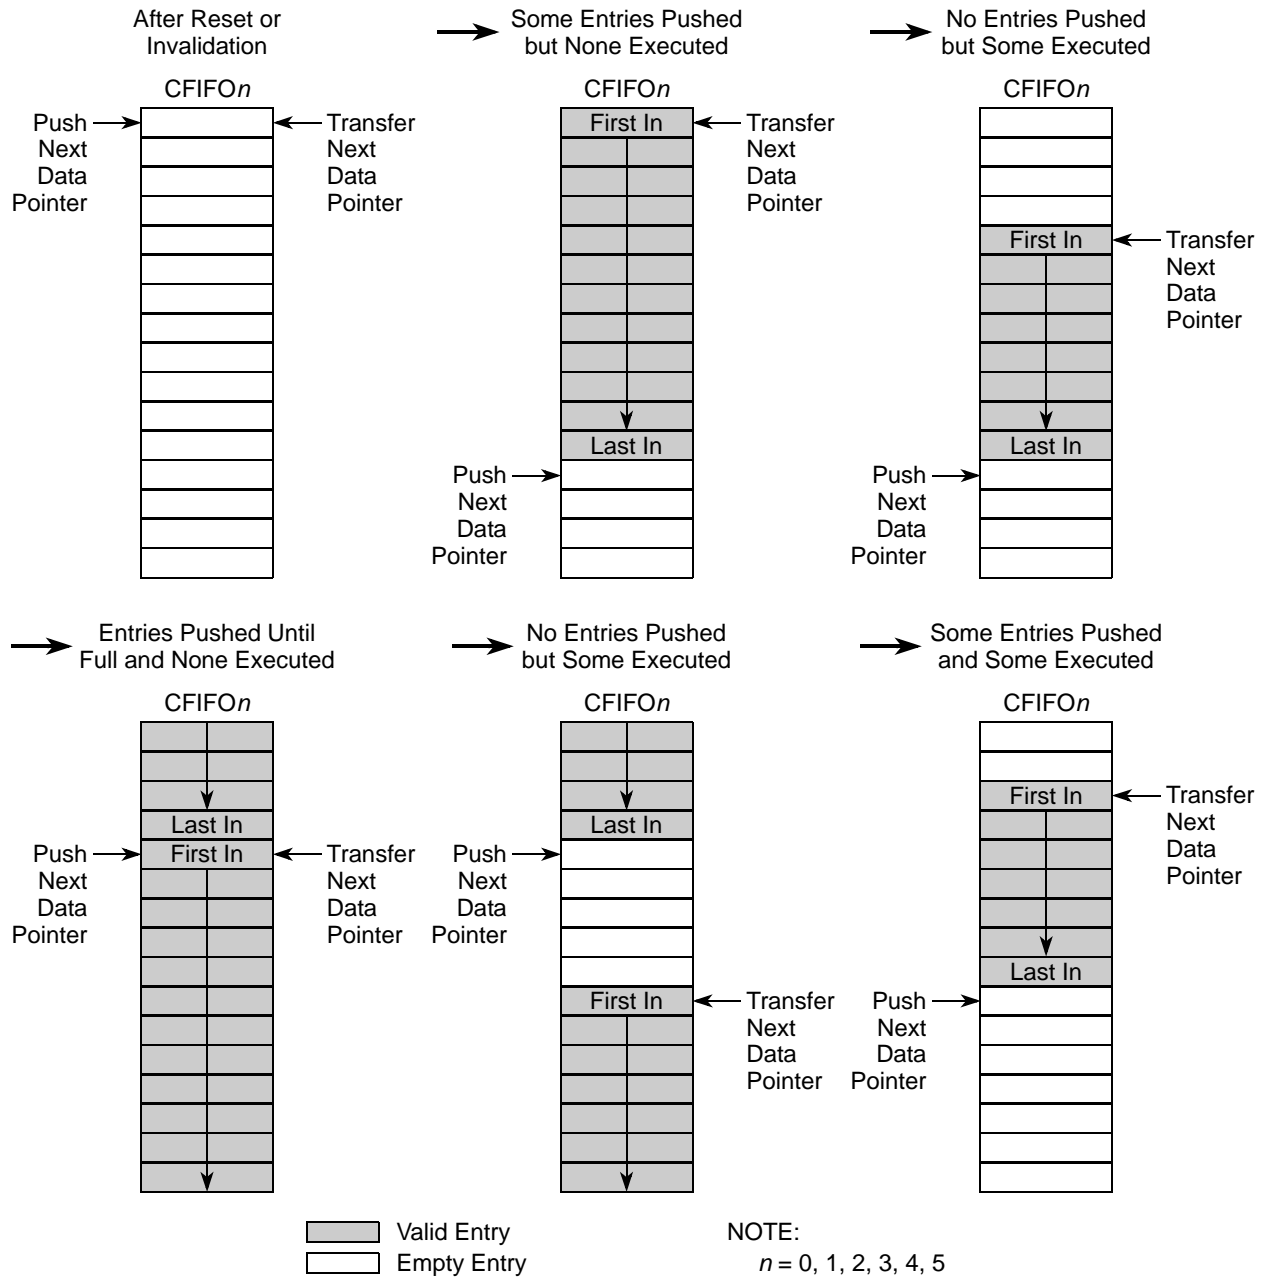

Figure 18-36. CFIFO Entry Pointer Example

18.4.3.2 CFIFO Prioritization and Command Transfer

The CFIFO priority is fixed according to the CFIFO number. A CFIFO with a smaller number has a higher priority. When commands of distinct CFIFOs are bound for the same destination (the same on-chip ADC), the higher priority CFIFO is always served first. A triggered, not-underflowing CFIFO starts to transfer commands when the following occur:

- Its commands are bound for an internal command buffer that is not full, and it is the highest priority triggered CFIFO sending commands to that buffer.

- Its commands are bound for an external command buffer that is not full, and it is the highest priority triggered CFIFO sending commands to an external buffer that is not full.

A triggered CFIFO with commands bound for a certain command buffer consecutively transfers its commands to the buffer until one of the following occurs:

- An asserted end of queue bit is reached.
- An asserted pause bit is encountered and the CFIFO is configured for edge trigger mode.
- CFIFO is configured for level trigger mode and a closed gate is detected.
- In case its commands are bound for an internal command buffer, a higher priority CFIFO that uses the same internal buffer is triggered.
- In case its commands are bound for an external command buffer, a higher priority CFIFO that uses an external buffer is triggered.

The prioritization logic of the eQADC, depicted in [Figure 18-37](#), is composed of three independent submodules: one that prioritizes CFIFOs with commands bound for ADC0, another that prioritizes CFIFOs with commands for ADC1, and a last one that prioritizes CFIFOs with commands for external command buffer 2 and buffer 3. As these three submodules are independent, simultaneous commands to ADC0, to ADC1, and to eQADC SSI transmit buffer are allowed. The hardware identifies the destination of a command by decoding the EB and BN bits in the command message (see [Section 18.4.1.2, “Message Format in eQADC,”](#) for details).

NOTE

Triggered but empty CFIFOs, underflowing CFIFOs, are not considered for prioritization. No data from these CFIFOs is sent to the on-chip ADCs or the external command buffers, and lower priority CFIFOs are not stopped from transferring commands.

Whenever ADC0 is able to receive new commands, the prioritization submodule selects the highest-priority triggered CFIFO with a command bound for ADC0, and sends it to the ADC. In case ADC0 is able to receive new entries but there are no triggered CFIFOs with commands bound for it, nothing is sent. The submodule prioritizing ADC1 usage behaves in the same way.

When the eQADC SSI is enabled and ready to start serial transmissions, the submodule prioritizing eQADC SSI usage writes command or null messages into the eQADC SSI transmit buffer, data written to the eQADC SSI transmit buffer is subsequently transmitted to the external device through the eQADC SSI link. The submodule writes commands to the eQADC SSI transmit buffer when there are triggered CFIFOs with commands bound for not-full external command buffers. The command written to the transmit buffer belongs to the highest priority CFIFO sending commands to an external buffer that is not full. This implies that a lower priority CFIFO can have its commands sent if a higher priority CFIFO cannot send its commands due to a full command buffer. The submodule writes null messages to the eQADC SSI transmit buffer when there are no triggered CFIFOs with commands bound for external command buffers, or when there are triggered CFIFOs with commands bound for external buffers but the external buffers are full. The eQADC monitors the status of the external buffers by decoding the BUSY fields of the incoming result messages from the external device (see [Section , “Result Message Format for External Device Operation,”](#) for details).

NOTE

When a higher priority CFIFO cannot send commands due to a full external command buffer, a lower priority CFIFO is served. When the higher priority CFIFO is ready to send commands, an interrupt to the command transfers from the lower priority CFIFO can result in CFIFO incoherence. Whether the lower priority CFIFO becomes non-coherent depends on the following:

- rate at which commands on the external ADCs are executed
- rate at which commands are transmitted to the external command buffers
- depth of those buffers.

After a serial transmission starts, the submodule monitors triggered CFIFOs and manages the abort of the serial transmissions. If a null message is transmitted, the serial transmission is aborted when all of the following conditions are met:

- A not-underflowing CFIFO in the TRIGGERED state has commands bound for an external command buffer that is not full, and it is the highest priority CFIFO sending commands to an external buffer that is not full
- The ABORT_ST bit of the command to be transmitted is asserted.
- The 26th bit of the currently transmitting null message is not shifted out.

The command from the CFIFO is then written into eQADC SSI transmit buffer, allowing for a new serial transmission to initiate.

In case a command is being transmitted, the serial transmission is aborted when all following conditions are met:

- CFIFO0 is in the TRIGGERED state, is not underflowing, and its current command is bound for an external command buffer that is not full.
- The ABORT_ST bit of the command to be transmitted is asserted.
- The 26th bit of the currently transmitting command has not being shifted out.

The command from CFIFO0 is then written into eQADC SSI transmit buffer, allowing for a new serial transmission to initiate.

NOTE

The aborted command is not popped from the pre-empted CFIFO, but is retransmitted as soon as it's the highest priority CFIFO sending commands to an unfilled external command buffer.

After a serial transmission is completed, the eQADC prioritizes the CFIFOs and schedules a command or a null message to be sent in the next serial transmission. After the data for the next transmission has been defined and scheduled, the eQADC can, under certain conditions, stretch the \overline{SDS} negation time to allow the schedule of new data for that transmission. This occurs when the eQADC acknowledges that the status of a higher-priority CFIFO has changed to the TRIGGERED state and attempts to schedule that CFIFO

command before $\overline{\text{SDS}}$ is asserted. Only commands of CFIFOs that have the ABORT_ST bit asserted can be scheduled in this manner. Under such conditions:

1. A CFIFO0 command is scheduled for the next transmission independently of the type of data that was previously scheduled. The time during which $\overline{\text{SDS}}$ is negated is stretched to allow the eQADC to load the CFIFO0 command and start its transmission.
2. CFIFO1-5 commands are only scheduled for the next transmission if the previously scheduled data was a null message. The time during which $\overline{\text{SDS}}$ is negated is stretched to allow the eQADC to load that command and start its transmission. However, if the previously scheduled data was a command, no rescheduling occurs and the next transmission starts without delays.

If a CFIFO becomes triggered while $\overline{\text{SDS}}$ is negated, but the eQADC only attempts to reschedule that CFIFO command after $\overline{\text{SDS}}$ is asserted, then the current transmission is aborted depending on if the conditions for that are met or not.

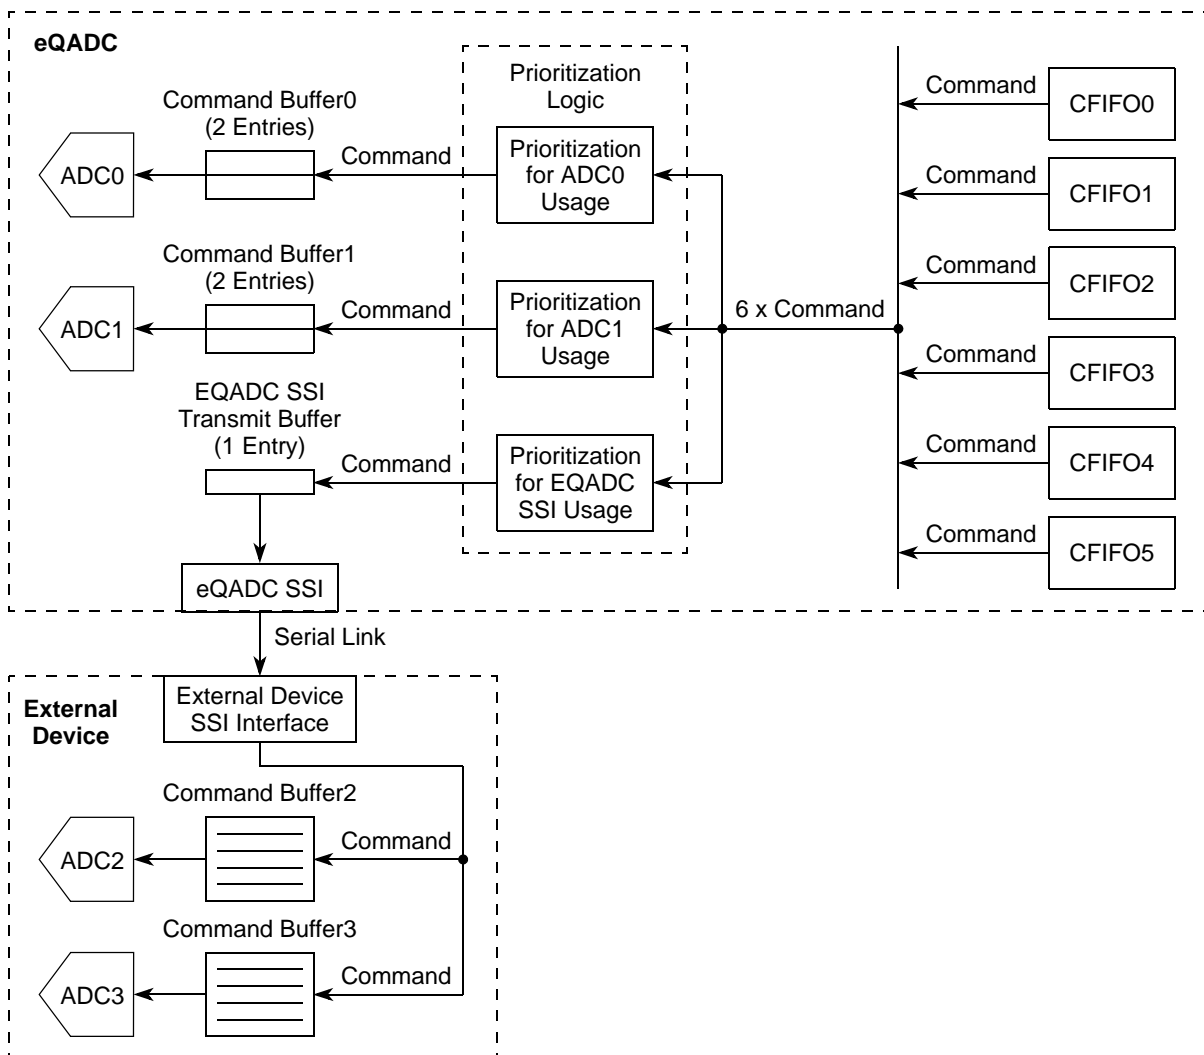

Figure 18-37. CFIFO Prioritization Logic

18.4.3.3 External Trigger from eTPU or eMIOS Channels

The six eQADC external trigger inputs can be connected to either an external pin (either ETRIG0, ETRIG1, GPIO206, or GPIO207), an eTPU channel, or an eMIOS channel. The input source for each eQADC external trigger is individually specified in the eQADC trigger input select register (SIU_ETISR) in the SIU block.

The eQADC trigger numbers specified by SIU_ETISR[TSEL(0-5)] correspond to CFIFO numbers 0-5. To calculate the CFIFO number that each trigger is connected to, divide the eDMA channel number by 2.

A complete description of the eTPU and eMIOS trigger function and configuration is found in [Section 6.4.5.1, “eQADC External Trigger Input Multiplexing.”](#)

18.4.3.4 External Trigger Event Detection

The digital filter length field in [Section 18.3.2.3, “eQADC External Trigger Digital Filter Register \(EQADC_ETDFR\),”](#) specifies the minimum number of system clocks that the external trigger signals 0 and 1 must be held at a logic level to be recognized as valid. All ETRIG signals are filtered. A counter for each queue trigger is implemented to detect a transition between logic levels. The counter counts at the system clock rate. The corresponding counter is cleared and restarted each time the signal transitions between logic levels. When the corresponding counter matches the value specified by the digital filter length field in [Section 18.3.2.3, “eQADC External Trigger Digital Filter Register \(EQADC_ETDFR\),”](#) the eQADC considers the ETRIG logic level to be valid and passes that new logic level to the rest of the eQADC.

The filter is only for filtering the ETRIG signal. Logic after the filter checks for transitions between filtered values, such as for detecting the transition from a filtered logic level zero to a filtered logic level one in rising edge external trigger mode. The eQADC can detect rising edge, falling edge, or level gated external triggers. The digital filter is always active independently of the status of the MODE n field in [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\),”](#) but the edge, level detection logic is only active when MODE n is set to a value different from disabled, and in case MODE n is set to single scan mode, when the SSS bit is asserted. Note that the time necessary for a external trigger event to result into a CFIFO status change is not solely determined by the DFL field in the [Section 18.3.2.3, “eQADC External Trigger Digital Filter Register \(EQADC_ETDFR\).”](#) After being synchronized to the system clock and filtered, a trigger event is checked against the CFIFO trigger mode. Only then, after a valid trigger event is detected, the eQADC accordingly changes the CFIFO status. Refer to [Figure 18-38](#) for an example.

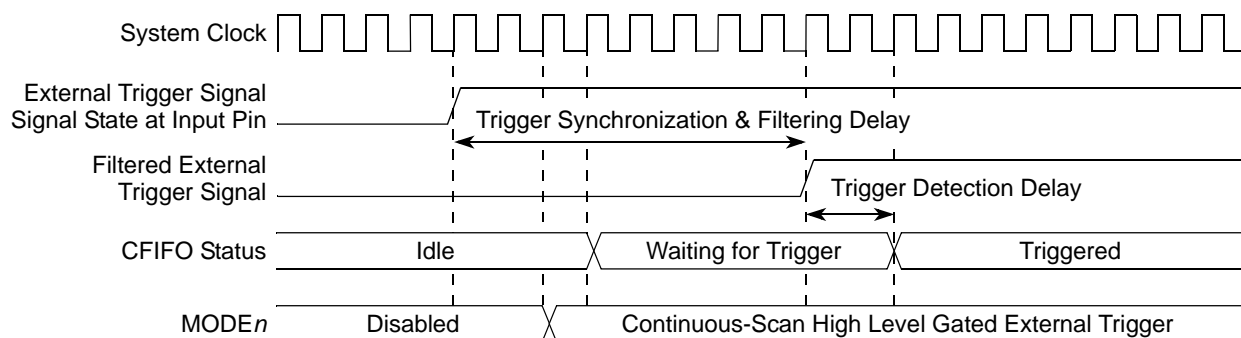

Figure 18-38. ETRIG Event Propagation Example

18.4.3.5 CFIFO Scan Trigger Modes

The eQADC supports two different scan modes, single-scan and continuous-scan. Refer to [Table 18-44](#) for a summary of these two scan modes. When a CFIFO is triggered, the eQADC scan mode determines whether the eQADC stops command transfers from a CFIFO, and waits for software intervention to rearm the CFIFO to detect new trigger events, upon detection of an asserted EOQ bit in the last transfer. Refer to [Section 18.4.1.2, “Message Format in eQADC,”](#) for details about command formats.

CFIFOs can be configured in single-scan or continuous-scan mode. When a CFIFO is configured in single-scan mode, the eQADC scans the command queue one time. The eQADC stops future command transfers from the triggered CFIFO after detecting the EOQ bit set in the last transfer. After a EOQ bit is detected, software involvement is required to rearm the CFIFO so that it can detect new trigger events.

When a CFIFO is configured for continuous-scan mode, no software involvement is necessary to rearm the CFIFO to detect new trigger events after an asserted EOQ is detected. In continuous-scan mode the whole command queue is scanned multiple times.

The eQADC also supports different triggering mechanisms for each scan mode. The eQADC does not transfer commands from a CFIFO until the CFIFO is triggered. The combination of scan modes and triggering mechanisms allows the support of different requirements for scanning input channels. The scan mode and trigger mechanism are configured by programming the $MODE_n$ field in [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\).”](#)

Enabled CFIFOs can be triggered by software or external trigger events. The elapsed time from detecting a trigger to transferring a command is a function of clock frequency, trigger synchronization, trigger filtering, programmable trigger events, command transfer, CFIFO prioritization, ADC availability, etc. Fast and predictable transfers can be achieved by ensuring that the CFIFO is not underflowing and that the target ADC can accept commands when the CFIFO is triggered.

18.4.3.5.1 Disabled Mode

The $MODE_n$ field in [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\),”](#) for all of the CFIFOs can be changed from any other mode to disabled at any time. No trigger event can initiate command transfers from a CFIFO which has its MODE field programmed to disabled.

NOTE

If $MODE_n$ is not disabled, it must not be changed to any other mode besides disabled. If $MODE_n$ is disabled and the CFIFO status is IDLE, $MODE_n$ can be changed to any other mode.

If $MODE_n$ is changed to disabled:

- The CFIFO execution status changes to IDLE. The timing of this change depends on whether a command is being transferred or not:
 - When no command transfer is in progress, the eQADC switches the CFIFO to IDLE status immediately.
 - When a command transfer to an on-chip ADC is in progress, the eQADC completes the transfer, updates TC_CF, and switches CFIFO status to IDLE. Command transfers to the internal ADCs are considered completed when a command is written to the relevant buffer.
 - When a command transfer to an external command buffer is in progress, the eQADC aborts the transfer and switches CFIFO status to IDLE. If the eQADC cannot abort the transfer, that is when the 26th bit of the serial message has been already shifted out, the eQADC completes the transfer, updates TC_CF and then switches CFIFO status to IDLE.
- The CFIFOs are not invalidated automatically. The CFIFO still can be invalidated by writing a 1 to the $CFINV_n$ bit (see [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\)”](#)). Certify that CFS has changed to IDLE before setting $CFINV_n$.
- The TC_CF_n value also is not reset automatically, but it can be reset by writing 0 to it.
- The $EQADC_FISR_n[SSS]$ bit (see [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\)”](#)) is negated. The SSS bit can be set even if a 1 is written to the $EQADC_CFCR[SSE]$ bit (see [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\)”](#)) in the same write that the $MODE_n$ field is changed to a value other than disabled.
- The trigger detection hardware is reset. If $MODE_n$ is changed from disabled to an edge trigger mode, a new edge, matching that edge trigger mode, is needed to trigger the command transfers from the CFIFO.

NOTE

CFIFO fill requests, which generated when CFFF is asserted, are not automatically halted when $MODE_n$ is changed to disabled. CFIFO fill requests are still generated until $EQADC_IDCR_n[CFFE]$ bit is cleared. Refer to [Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 \(EQADC_IDCRn\)”](#).

18.4.3.5.2 Single-Scan Mode

In single-scan mode, a single pass through a sequence of command messages in the user-defined command queue is performed.

In single-scan software trigger mode, the CFIFO is triggered by an asserted single-scan status bit, $EQADC_FISR_n[SSS]$ (see [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5](#)

(EQADC_FISRn”). The SSS bit is set by writing 1 to the single-scan enable bit, EQADC_CFCRn[SSE] (see Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 (EQADC_CFCRn”)”).

In single-scan edge or level trigger mode, the respective triggers are only detected when the SSS bit is asserted. When the SSS bit is negated, all trigger events for that CFIFO are ignored. Writing a 1 to the SSE bit can be done during the same write cycle that the CFIFO operation mode is configured.

Only the eQADC can clear the SSS bit. After SSS is asserted, it remains asserted until the eQADC completes the command queue scan, or the CFIFO operation mode, EQADC_CFCRn[MODEn] (see Section 18.3.2.6) is changed to disabled. The SSSn bit is negated while MODEn is disabled.

Single-Scan Software Trigger

When single-scan software trigger mode is selected, the CFIFO is triggered by an asserted SSS bit. The SSS bit is asserted by writing 1 to the SSE bit. Writing to SSE while SSS is already asserted does not have any effect on the state of the SSS bit, nor does it cause a trigger overrun event.

The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using an available on-chip ADC or an external command buffer that is not full. When an asserted EOQ bit is encountered, the eQADC clears the SSS bit. Setting the SSS bit is required for the eQADC to start the next scan of the queue.

The pause bit has no effect in single-scan software trigger mode.

Single-Scan Edge Trigger

When SSS is asserted and an edge triggered mode is selected for a CFIFO, an appropriate edge on the associated trigger signal causes the CFIFO to become triggered. For example, if rising-edge trigger mode is selected, the CFIFO becomes triggered when a rising edge is sensed on the trigger signal. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using an available on-chip ADC, or an external command buffer that is not full.

When an asserted EOQ bit is encountered, the eQADC clears SSS and stops command transfers from the CFIFO. An asserted SSS bit and a subsequent edge trigger event are required to start the next scan for the CFIFO. When an asserted pause bit is encountered, the eQADC stops command transfers from the CFIFO, but SSS remains set. Another edge trigger event is required for command transfers to continue. A trigger overrun happens when the CFIFO is in a TRIGGERED state and an edge trigger event is detected.

Single-Scan Level Trigger

When SSS is asserted and a level gated trigger mode is selected, the input level on the associated trigger signal puts the CFIFO in a TRIGGERED state. When the CFIFO is set to high-level gated trigger mode, a high level signal opens the gate, and a low level closes the gate. When the CFIFO is set to low-level gated trigger mode, a low level signal opens the gate, and a high level closes the gate. If the corresponding level is already present, setting the SSS bit triggers the CFIFO. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using an available on-chip ADC or an external command buffer that is not full.

The eQADC clears the SSS bit and stops transferring commands from a triggered CFIFO when an asserted EOQ bit is encountered or when CFIFO status changes from triggered due to the detection of a closed gate.

If a closed gate is detected while no command transfers are taking place and the CFIFO status is triggered, the CFIFO status is immediately changed to IDLE, the SSS bit is negated, and the PF flag is asserted. If a closed gate is detected during the serial transmission of a command to the external device, it has no effect on the CFIFO status until the transmission completes. After the transmission is completed, the TC_CF counter is updated, the SSS bit is negated, the PF flag is asserted, and the CFIFO status is changed to IDLE. An asserted SSS bit and a level trigger are required to restart the CFIFO. Command transfers restart from the point they have stopped.

If the gate closes and opens during the same serial transmission of a command to the external device, it has no effect on the CFIFO status or on the PF flag, but the TORF flag asserts as shown in [Figure 18-40](#). Therefore, closing the gate for a period less than a serial transmission time interval does not guarantee that the closure affects command transfers from a CFIFO.

The pause bit has no effect in single-scan level trigger mode.

18.4.3.5.3 Continuous-Scan Mode

In continuous-scan mode, multiple passes looping through a sequence of command messages in a command queue are executed. When a CFIFO is programmed for a continuous-scan mode, the EQADC_CFCRn[SSE] (see [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\)”](#)) does not have any effect.

Continuous-Scan Software Trigger

When a CFIFO is programmed to continuous-scan software trigger mode, the CFIFO is triggered immediately. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using an available on-chip ADC or an external command buffer that is not full. When a CFIFO is programmed to run in continuous-scan software trigger mode, the eQADC does not halt transfers from the CFIFO until the CFIFO operation mode is modified to disabled or a higher priority CFIFO preempts it. Although command transfers do not stop upon detection of an asserted EOQ bit, the EOQF is set and, if enabled, an EOQ interrupt request is generated.

The pause bit has no effect in continuous-scan software trigger mode.

Continuous-Scan Edge Trigger

When rising, falling, or either edge trigger mode is selected for a CFIFO, a corresponding edge on the associated ETRIG signal places the CFIFO in a TRIGGERED state. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using an available on-chip ADC or an external command buffer that is not full.

When an EOQ or a pause is encountered, the eQADC halts command transfers from the CFIFO and, if enabled, the appropriate interrupt requests are generated. Another edge trigger event is required to resume command transfers but no software involvement is required to rearm the CFIFO to detect such event.

A trigger overrun happens when the CFIFO is already in a TRIGGERED state and a new edge trigger event is detected.

Continuous-Scan Level Trigger

When high or low level gated trigger mode is selected, the input level on the associated trigger signal places the CFIFO in a TRIGGERED state. When high-level gated trigger is selected, a high-level signal opens the gate, and a low level closes the gate. The CFIFO commands start to be transferred when the CFIFO becomes the highest priority CFIFO using an available on-chip ADC or an external buffer that is not full. Although command transfers do not stop upon detection of an asserted EOQ bit at the end of a command transfer, the EOQF is asserted and, if enabled, an EOQ interrupt request is generated.

The eQADC stops transferring commands from a triggered CFIFO when CFIFO status changes from triggered due to the detection of a closed gate. If a closed gate is detected while no command transfers are taking place and the CFIFO status is TRIGGERED, the CFIFO status is immediately changed to waiting for trigger and the PF flag is asserted. If a closed gate is detected during the serial transmission of a command to the external device, it has no effect on the CFIFO status until the transmission completes. After the transmission is completed, the TC_CF counter is updated, the PF flag is asserted, and the CFIFO status is changed to waiting for trigger. Command transfers restart as the gate opens.

If the gate closes and opens during the same serial transmission of a command to the external device, it has no effect on the CFIFO status or on the PF flag, but the TORF flag asserts as shown in [Figure 18-40](#). Therefore, closing the gate for a period less than a serial transmission time interval does not guarantee that command transfers from a CFIFO are closed.

The pause bit has no effect in continuous-scan level trigger mode.

18.4.3.5.4 CFIFO Scan Trigger Mode Start/Stop Summary

[Table 18-44](#) summarizes the start and stop conditions of command transfers from CFIFOs for all of the single-scan and continuous-scan trigger modes.

Table 18-44. CFIFO Scan Trigger Mode—Command Transfer Start/Stop Summary

Trigger Mode	Requires Asserted SSS to Recognize Trigger Events?	Command Transfer Start/Restart Condition	Stop on asserted EOQ bit ¹ ?	Stop on asserted Pause bit ² ?	Other Command Transfer Stop Condition ^{3 4}
Single Scan Software	Not Applicable	Asserted SSS bit.	Yes	No	None.
Single Scan Edge	Yes	A corresponding edge occurs when the SSS bit is asserted.	Yes	Yes	None.
Single Scan Level	Yes	Gate is opened when the SSS bit is asserted.	Yes	No	The eQADC also stops transfers from the CFIFO when CFIFO status changes from triggered due to the detection of a closed gate. ⁵
Continuous Scan Software	No	CFIFO starts automatically after being configured into this mode.	No	No	None.

Table 18-44. CFIFO Scan Trigger Mode—Command Transfer Start/Stop Summary

Trigger Mode	Requires Asserted SSS to Recognize Trigger Events?	Command Transfer Start/Restart Condition	Stop on asserted EOQ bit ¹ ?	Stop on asserted Pause bit ² ?	Other Command Transfer Stop Condition ^{3 4}
Continuous Scan Edge	No	A corresponding edge occurs.	Yes	Yes	None.
Continuous Scan Level	No	Gate is opened.	No	No	The eQADC also stops transfers from the CFIFO when CFIFO status changes from triggered due to the detection of a closed gate. ⁵

¹ Refer to [Section 18.4.3.6.2, “Command Queue Completion Status,”](#) for more information on EOQ.

² Refer to [Section 18.4.3.6.3, “Pause Status,”](#) for more information on pause.

³ The eQADC always stops command transfers from a CFIFO when the CFIFO operation mode is disabled.

⁴ The eQADC always stops command transfers from a CFIFO when a higher priority CFIFO is triggered. Refer to [Section 18.4.3.2, “CFIFO Prioritization and Command Transfer,”](#) for information on CFIFO priority.

⁵ If a closed gate is detected while no command transfers are taking place, it has an immediate effect on the CFIFO status. If a closed gate is detected during the serial transmission of a command to the external device, it has no effect on the CFIFO status until the transmission completes.

18.4.3.6 CFIFO and Trigger Status

18.4.3.6.1 CFIFO Operation Status

Each CFIFO has its own CFIFO status field. CFIFO status (CFS) can be read from EQADC_CFSSR (refer to [Section 18.3.2.11, “eQADC CFIFO Status Register \(EQADC_CFSR\).”](#) [Figure 18-39](#) and [Table 18-45](#) indicate the CFIFO status switching condition. Refer to [Table 18-18](#) for the meaning of each CFIFO operation status. The last CFIFO to transfer a command to an on-chip ADC can be read from the LCFT_n ($n=0,1$) fields (see [Section 18.3.2.10, “eQADC CFIFO Status Snapshot Registers 0–2 \(EQADC_CFSSR_n\).”](#) The last CFIFO to transfer a command to a specific external command buffer can be identified by reading the EQADC_CFSSR_n[LCFTSSI] and EQADC_CFSSR_n[ENI] fields (see [Section 18.3.2.10, “eQADC CFIFO Status Snapshot Registers 0–2 \(EQADC_CFSSR_n\).”](#)

Figure 18-39. State Machine of CFIFO Status

Table 18-45. Command FIFO Status Switching Condition

No.	From Current CFIFO Status (CFS)	To New CFIFO Status (CFS)	Status Switching Condition
1	IDLE (00)	IDLE (0b00)	<ul style="list-style-type: none"> CFIFO mode is programmed to disabled, OR CFIFO mode is programmed to single-scan edge or level trigger mode and SSS is negated.
2		WAITING FOR TRIGGER (0b10)	<ul style="list-style-type: none"> CFIFO mode is programmed to continuous-scan edge or level trigger mode, OR CFIFO mode is programmed to single-scan edge or level trigger mode and SSS is asserted, OR CFIFO mode is programmed to single-scan software trigger mode.
3		TRIGGERED (0b11)	<ul style="list-style-type: none"> CFIFO mode is programmed to continuous-scan software trigger mode
4	WAITING FOR TRIGGER (10)	IDLE (0b00)	<ul style="list-style-type: none"> CFIFO mode is modified to disabled mode.
5		WAITING FOR TRIGGER (0b10)	<ul style="list-style-type: none"> No trigger occurred.
6		TRIGGERED (0b11)	<ul style="list-style-type: none"> Appropriate edge or level trigger occurred, OR CFIFO mode is programmed to single-scan software trigger mode and SSS bit is asserted.

Table 18-45. Command FIFO Status Switching Condition (continued)

No.	From Current CFIFO Status (CFS)	To New CFIFO Status (CFS)	Status Switching Condition
7	TRIGGERED (11)	IDLE (0b00)	<ul style="list-style-type: none"> CFIFO in single-scan mode, eQADC detects the EOQ bit asserted at end of command transfer, and CFIFO mode is not modified to disabled, OR CFIFO, in single-scan level trigger mode, and the gate closes while no commands are being transferred from the CFIFO, and CFIFO mode is not modified to disabled, OR CFIFO, in single-scan level trigger mode, and eQADC detects a closed gated at end of command transfer, and CFIFO mode is not modified to disabled, OR CFIFO mode is modified to disabled mode and CFIFO was not transferring commands. CFIFO mode is modified to disabled mode while CFIFO was transferring commands, and CFIFO completes or aborts the transfer.
8		WAITING FOR TRIGGER (0b10)	<ul style="list-style-type: none"> CFIFO in single or continuous-scan edge trigger mode, eQADC detects the pause bit asserted at the end of command transfer, the EOQ bit in the same command is negated, and CFIFO mode is not modified to disabled, OR CFIFO in continuous-scan edge trigger mode, eQADC detects the EOQ bit asserted at the end of command transfer, and CFIFO mode is not modified to disabled, OR CFIFO, in continuous-scan level trigger mode, and the gate closes while no commands are being transferred from the CFIFO, and CFIFO mode is not modified to disabled, OR CFIFO, in continuous-scan level trigger mode, and eQADC detects a closed gated at end of command transfer, and CFIFO mode is not modified to disabled.
9		TRIGGERED (0b11)	<ul style="list-style-type: none"> No event to switch to IDLE or WAITING FOR TRIGGER status has happened.

18.4.3.6.2 Command Queue Completion Status

The end of queue flag, EQADC_FISRn[EOQF] (see [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\)”](#)) is asserted when the eQADC completes the transfer of a CFIFO entry with an asserted EOQ bit. Software sets the EOQ bit in the last command message of a user-defined command queue to indicate that this entry is the end of the queue. Refer to [Section 18.4.1.2, “Message Format in eQADC,”](#) for information on command message formats. The transfer of entries bound for the on-chip ADCs is considered completed when they are stored in the appropriate command buffer. The transfer of entries bound for the external device is considered completed when the serial transmission of the entry is completed.

The command with a EOQ bit asserted is valid and is transferred. When EQADC_CFCRn[EOQIE] (refer to [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\)”](#)) and EQADC_FISRn[EOQF] are asserted, the eQADC generates an end of queue interrupt request.

In single-scan modes, command transfers from the corresponding CFIFO cease when the eQADC completes the transfer of a entry with an asserted EOQ. Software involvement is required to rearm the CFIFO so that it can detect new trigger events.

NOTE

An asserted EOQFn only implies that the eQADC has finished transferring a command with an asserted EOQ bit from CFIFOn. It does not imply that result data for the current command and for all previously transferred commands has been returned to the appropriate RFIFO.

18.4.3.6.3 Pause Status

In edge trigger mode, when the eQADC completes the transfer of a CFIFO entry with an asserted pause bit, the eQADC stop future command transfers from the CFIFO and set EQADC_FISRn[PF]. The eQADC ignores the pause bit in command messages in any software level trigger mode. The eQADC sets the PF flag upon detection of an asserted pause bit only in single or continuous-scan edge trigger mode. When the PF flag is set for a CFIFO in single-scan edge trigger mode, the EQADC_FISRn[SSS] bit is not cleared.

Refer to the following sections for more information:

[Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\)”](#)

[Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\)”](#)

[Section 18.4.1.2, “Message Format in eQADC,”](#) for information on command message formats.

In level trigger mode, the definition of the PF flag has been redefined. In level trigger mode, when CFIFOn is in TRIGGERED status, PFn is set when the CFIFO status changes from TRIGGERED due to detection of a closed gate. The pause flag interrupt routine can be used to verify if the a complete scan of the command queue was performed. If a closed gate is detected while no command transfers are taking place, it has immediate effect on the CFIFO status. If a closed gate is detected during the serial transmission of a command to the external device, it has no effect on the CFIFO status until the transmission completes.

When EQADC_CFCR[PIE] and EQADC_FISRn[PF] are asserted, the eQADC generates a pause interrupt request. Refer to [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\)”](#) for more information.

NOTE

In edge-trigger mode, an asserted PFn only implies that the eQADC finished transferring a command with an asserted pause bit from CFIFOn. It does not imply that result data for the current command and for all previously transferred commands has been returned to the RFIFO.

NOTE

In software or level trigger mode, when the eQADC completes the transfer of an entry from CFIFOn with an asserted pause bit, PFn is not set and the command transfers continues without pausing.

18.4.3.6.4 Trigger Overrun Status

When a CFIFO is configured for edge or level trigger mode and is in a TRIGGERED state, an additional trigger event for the same CFIFO causes a trigger overrun:

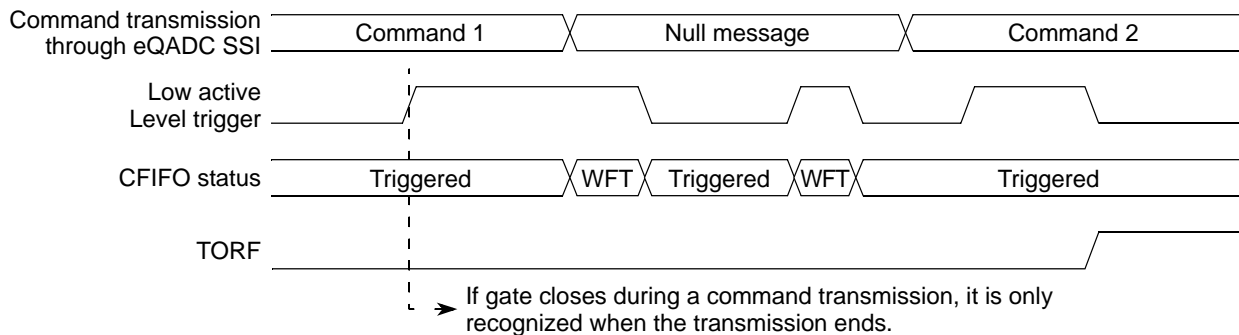

1. The trigger overrun bit for the CFIFO is set (EQADC_FISRn[TORFn] = 1)
2. The EQADC_CFCRn[TORIE] and EQADC_FISRn[TORF] assert
3. The eQADC generates a trigger overrun interrupt request.

Refer to the following sections for more information:

[Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\)”](#)

[Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\)”](#)

For CFIFOs configured for level trigger mode, a trigger overrun event is detected only when the gate closes and reopens during a single serial command transmission as shown in [Figure 18-40](#).

- Assumptions:
- 1) CFIFO programmed to 'continuous-scan low level gated external trigger mode'.
 - 2) Command 2 has its ABORT_ST bit negated.
 - 3) There are no other CFIFOs using the serial interface.
- WFT = Waiting for Trigger

Figure 18-40. Trigger Overrun on Level Trigger Mode CFIFOs

NOTE

The trigger overrun flag is not set for CFIFOs configured for software trigger mode.

18.4.3.6.5 Command Sequence Non-Coherency Detection

The eQADC provides a mechanism to indicate if a command sequence has been completely executed without interruptions. A command sequence is defined as a group of consecutive commands bound for the same ADC and it is expected to be executed without interruptions. A command sequence is coherent if its commands are executed in order without interruptions. Because commands are stored in the ADC's command buffers before being executed in the eQADC, a command sequence is coherent if, while it is transferring commands to an on-chip ADC command buffer, the buffer is only fed with commands from that sequence without ever becoming empty.

A command sequence starts when:

- A CFIFO in TRIGGERED state transfers its first command to an on-chip ADC.

- The CFIFO is constantly transferring commands and the previous command sequence ended.
- The CFIFO resumes command transfers after being interrupted.

And a command sequence ended when:

- An asserted EOQ bit is detected on the last transferred command.
- CFIFO is in edge-trigger mode and asserted pause bit is detected on the last transferred command.
- The ADC to which the next command is bound is different from the ADC to which the last command was transferred.

Figure 18-41 shows examples of how the eQADC would detect command sequences when transferring commands from a CFIFO. The smallest possible command sequence can have a single command as shown in example 3 of Figure 18-41.

User Command Queue with Two Command Sequences

1	CF5_ADC1_CM0
2	CF5_ADC1_CM1
3	CF5_ADC1_CM2
4	CF5_ADC1_CM3(Pause=1)
5	CF5_ADC1_CM4
6	CF5_ADC1_CM5
7	CF5_ADC1_CM6(EOQ=1)

Example 1

Assuming that these commands are transferred by a CFIFO configured for edge trigger mode and the command transfers are never interrupted, the eQADC would check for non-coherency of two command sequences: one formed by commands 0, 1, 2, 3, and the other by commands 4, 5, 6.

User Command Queue with Three Command Sequences

1	CF5_ADC1_CM0
2	CF5_ADC1_CM1
3	CF5_ADC1_CM2
4	CF5_ADC0_CM3
5	CF5_ADC0_CM4
6	CF5_ADC1_CM5
7	CF5_ADC1_CM6(EOQ=1)

Example 2

Assuming that command transfers from the CFIFO are never interrupted, the eQADC would check for non-coherency of three command sequences. The first being formed by commands 0, 1, 2, the second by commands 3, 4 and the third by commands 5, 6. Note that even when the commands of this queue are transferred through a CFIFO in continuous-scan mode, the first three commands and the last two commands of this command queue would still constitute two distinct command sequences, although they are all bound for the same ADC, because an asserted EOQ ends a command sequence.

User Command Queue with a Seven Command Sequence

1	CF5_ADC1_CM0
2	CF5_ADC2_CM1
3	CF5_ADC3_CM2
4	CF5_ADC1_CM3
5	CF5_ADC0_CM4
6	CF5_ADC2_CM5
7	CF5_ADC1_CM6(EOQ=1)

Example 3

The eQADC would check for non-coherency of seven command sequences, all containing a single command, but NCF would never get set.

CF_n_ADCa_CMD_n – Command *n* in CFIFO_n bound for ADC_a (ADC3 and ADC4 are external devices associated with external command buffers 2 and 3).

Figure 18-41. Command Sequence Examples

The NCF flag is used to indicate command sequence non-coherency. When the NCF_n flag is asserted, it indicates that the command sequence being transferred through CFIFO_n became non-coherent. The NCF flag only becomes asserted for CFIFOs in a TRIGGERED state.

A command sequence is non-coherent when, after transferring the first command of a sequence from a CFIFO to a buffer, it cannot successively send all the other commands of the sequence before any of the following conditions are true:

- The CFIFO through which commands are being transferred is pre-empted by a higher priority CFIFO which sends commands to the same ADC. The NCF flag becomes asserted immediately after the first command transfer from the pre-empting CFIFO, that is the higher priority CFIFO, to the ADC in use is completed. Refer to [Figure 18-43](#).
- The external command buffer in use becomes empty. (Only the fullness of external buffers is monitored because the fill rate for internal ADC buffers is many times faster than the drain rate, and each has a dedicated priority engine.) This case happens when different CFIFOs attempt to use different external command buffers and the higher priority CFIFO bars the lower priority one from sending new commands to its buffer—see [Figure 18-44](#). An external command buffer is considered empty when the corresponding BUSY field in the last result message received from external device is encoded as “Send available commands - buffer is empty”. Refer to [Section , “Result Message Format for External Device Operation.”](#) The NCF flag becomes asserted immediately after the eQADC detects that the external buffer in use becomes empty.

NOTE

After the transfer of a command sequence to an external command buffer starts, the eQADC ignores, for non-coherency detection purposes, the BUSY fields captured at the end of the first serial transmission. Thereafter, all BUSY fields captured at the end of consecutive serial transmissions are used to check the fullness of that external command buffer. This is done because the eQADC only updates its external ADC command buffer status record when it receives a serial message, resulting that the record kept by the eQADC is always outdated by, at least, the length of one serial transmission. This prevents a CFIFO from immediately becoming non-coherent when it starts transferring commands to an empty external command buffer. Refer to [Figure 18-42](#) for an example.

- Assumptions: 1) The CFIFO starts sending commands to an external command buffer when triggered.
 2) Execution of a command on the external device takes longer than the time to complete three serial transmissions.

Figure 18-42. External Command Buffer Status Detection at Command Sequence Transfer Start

Table 18-46. External Buffer Status

Capture Point at eQADC	Buffer Status at External Device	Buffer Status as Captured by the eQADC	Used for NCF Detection on the eQADC?
(a)	EMPTY	EMPTY	No change
(b)	1 ENTRY	EMPTY	No
(c)	2 ENTRY	1 ENTRY	Yes

After the start of command sequence transfer, the eQADC checks for the command sequence coherency until the command sequence ends or one of the following conditions are true:

- Command sequence is non-coherent.
- CFIFO status changes from the TRIGGERED state
- CFIFO underflow occurs

NOTE

The NCF flag is asserted if an external command buffer empty event is detected at the same time the eQADC stops checking for the coherency of a command sequence.

After command transfers restart or continue, the non-coherency hardware operate as if the command sequence started from that point. [Figure 18-45](#) depicts how the non-coherency hardware operates when a non-coherency event is detected.

NOTE

If $MODE_n$ is changed to disabled while a CFIFO is transferring commands, the NCF flag for that CFIFO is not asserted.

NOTE

When the eQADC enters debug or stop mode while a command sequence is executing, the NCF asserts if an empty external command buffer is detected after debug or stop mode exits.

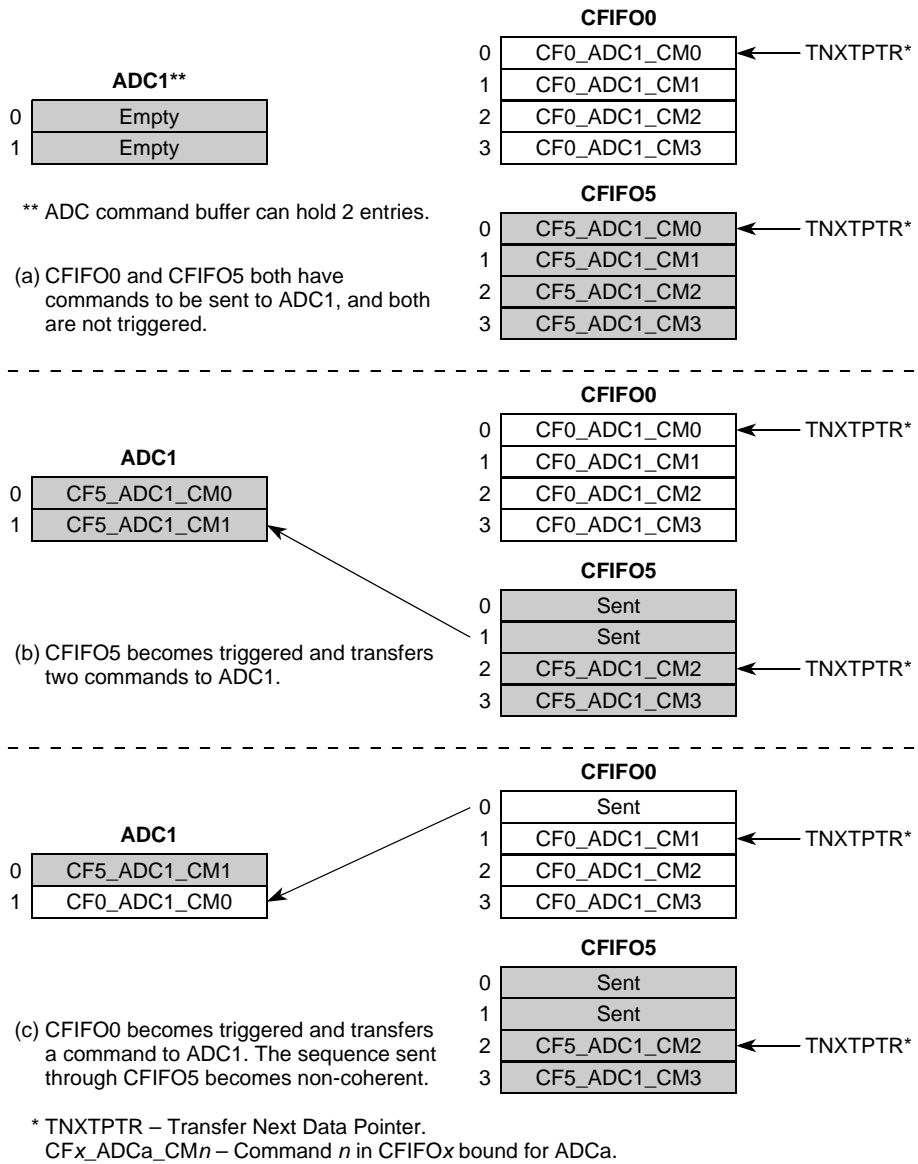

Figure 18-43. Non-Coherency Event When Different CFIFOs Use the Same Buffer

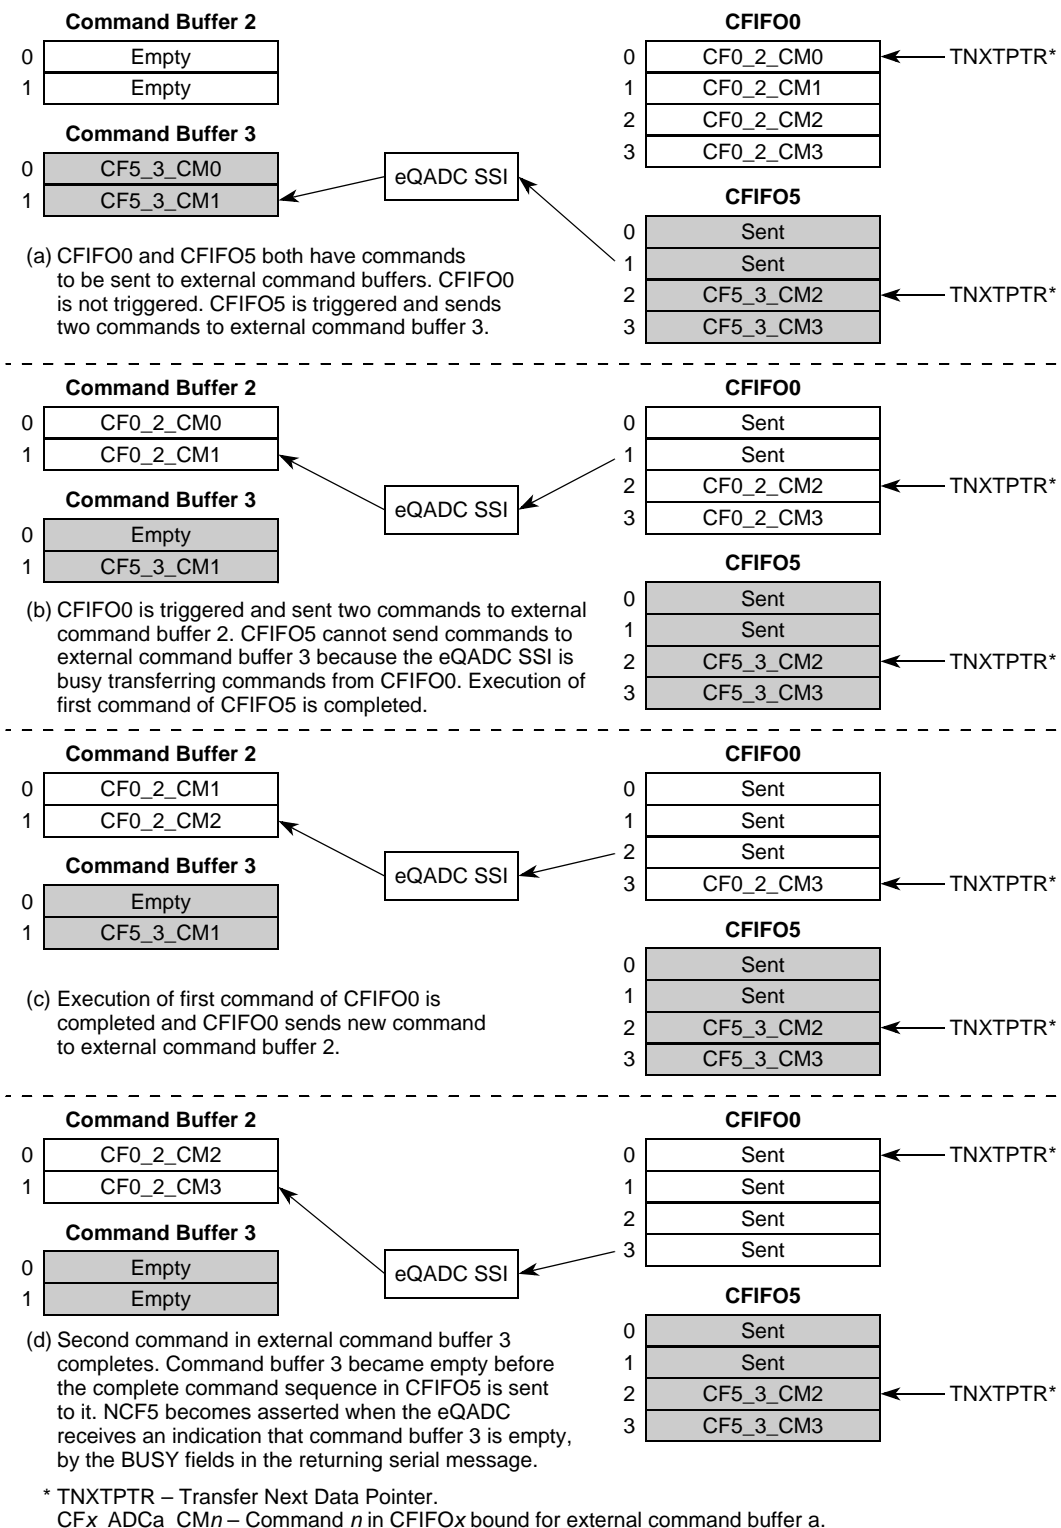

Figure 18-44. Non-Coherency Event When Different CFIFOs Are Using Different External Command Buffers

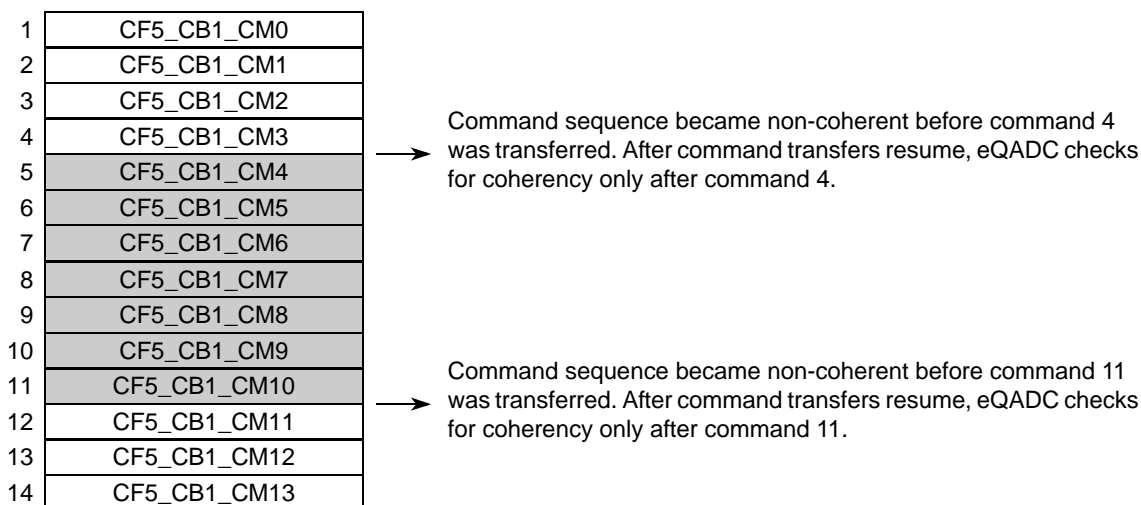

Figure 18-45. Non-coherency Detection When Transfers From a Command Sequence Are Interrupted

18.4.4 Result FIFOs

18.4.4.1 RFIFO Basic Functionality

There are six RFIFOs located in the eQADC. Each RFIFO is four entries deep, and each RFIFO entry is 16 bits long. Each RFIFO serves as a temporary storage location for the one of the result queues allocated in system memory. All result data is saved in the RFIFOs before being moved into the system result queues. When an RFIFO is not empty, the eQADC sets the corresponding EQADC_FISR_n[RFDF] (see Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISR_n)”). If EQADC_IDCR_n[RFDE] is asserted (see Section 18.3.2.7), the eQADC generates a request so that the RFIFO entry is moved to a result queue. An interrupt request, served by the host CPU, is generated when EQADC_IDCR_n[RFDS] is negated, and an eDMA request, served by the eDMA, is generated when RFDS is asserted. The host CPU or the eDMA responds to these requests by reading EQADC_RFPR_n (see Section 18.3.2.5, “eQADC Result FIFO Pop Registers 0–5 (EQADC_RFPR_n)”) to retrieve data from the RFIFO.

NOTE

Reading a word, halfword, or any bytes from EQADC_RFPR_n pops an entry from RFIFO_n, and the RFCTR_n field is decremented by 1.

The eDMA controller should be configured to read a single result (16-bit data) from the RFIFO pop registers for every asserted eDMA request it acknowledges. Refer to Section 18.5.2, “eQADC/eDMA Controller Interface” for eDMA controller configuration guidelines.

Figure 18-46 describes the important components in the RFIFO. Each RFIFO is implemented as a circular set of registers to avoid the need to move all entries at each push/pop operation. The pop next data pointer always points to the next RFIFO message to be retrieved from the RFIFO when reading eQADC_RFPR. The receive next data pointer points to the next available RFIFO location for storing the next incoming

message from the on-chip ADCs or from the external device. The RFIFO counter logic counts the number of entries in RFIFO and generates interrupt or eDMA requests to drain the RFIFO.

EQADC_FISR n [POPNEXTPTR] (see [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISR \$n\$ \)”](#)) indicates which entry is currently being addressed by the pop next data pointer, and EQADC_FISR n [RFCTR] provides the number of entries stored in the RFIFO. Using POPNEXTPTR and RFCTR, the absolute addresses for pop next data pointer and receive next data pointer can be calculated using the following formulas:

$$\begin{aligned} \text{Pop Next Data Pointer Address} &= \text{RFIFO}_n\text{_BASE_ADDRESS} + \text{POPNEXTPTR}_n * 4 \\ \text{Receive Next Data Pointer Address} &= \text{RFIFO}_n\text{_BASE_ADDRESS} + \\ &[(\text{POPNEXTPTR}_n + \text{RFCTR}_n) \bmod \text{RFIFO_DEPTH}] * 4 \end{aligned}$$

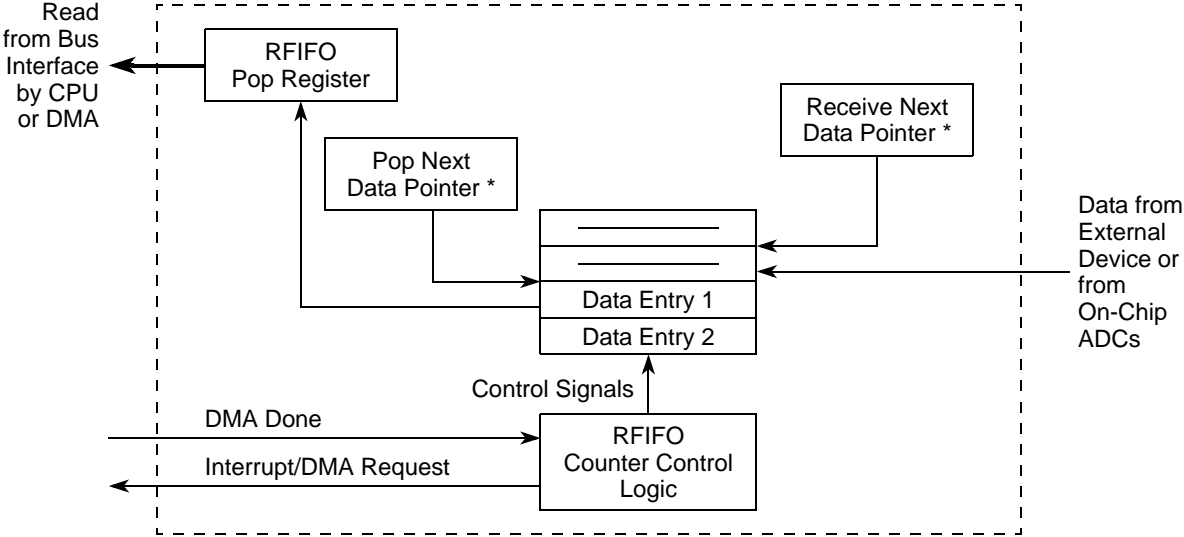

where

- $a \bmod b$ returns the remainder of the division of a by b .
- RFIFO n _BASE_ADDRESS is the smallest memory mapped address allocated to an RFIFO n entry.
- RFIFO_DEPTH is the number of entries contained in a RFIFO - four in this implementation.

When a new message arrives and RFIFO n is not full, the eQADC copies its contents into the entry pointed by receive next data pointer. The RFIFO counter EQADC_FISR n [RFCTR n] (see [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISR \$n\$ \)”](#)) is incremented by 1, and the receive next data pointer n is also incremented by 1 (or wrapped around) to point to the next empty entry in RFIFO n . However, if the RFIFO n is full, the eQADC sets the EQADC_FISR n [RFOF] (see [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISR \$n\$ \)”](#)). The RFIFO n does not overwrite the older data in the RFIFO, the new data is ignored, and the receive next data pointer n is not incremented or wrapped around. RFIFO n is full when the receive next data pointer n equals the pop next data pointer n and RFCTR n is not 0. RFIFO n is empty when the receive next data pointer n equals the pop next data pointer n and RFCTR n is 0.

When the eQADC RFIFO pop register n is read and the RFIFO n is not empty, the RFIFO counter RFCTR n is decremented by 1, and the pop next data pointer is incremented by 1 (or wrapped around) to point to the next RFIFO entry.

When the eQADC RFIFO pop register n is read and RFIFO n is empty, eQADC does not decrement the counter value and the pop next data pointer n is not updated. The read value is undefined.

* All RFIFO entries are memory mapped and the entries addressed by these pointers can have their absolute addresses calculated using POPNXTPTR and RFCTR.

Figure 18-46. RFIFO Diagram

The detailed behavior of the pop next data pointer and receive next data pointer is described in the example shown in [Figure 18-47](#) where an RFIFO with 16 entries is shown for clarity of explanation, the actual hardware implementation has only four entries. In this example, RFIFO_n with 16 entries is shown in sequence after popping or receiving entries.

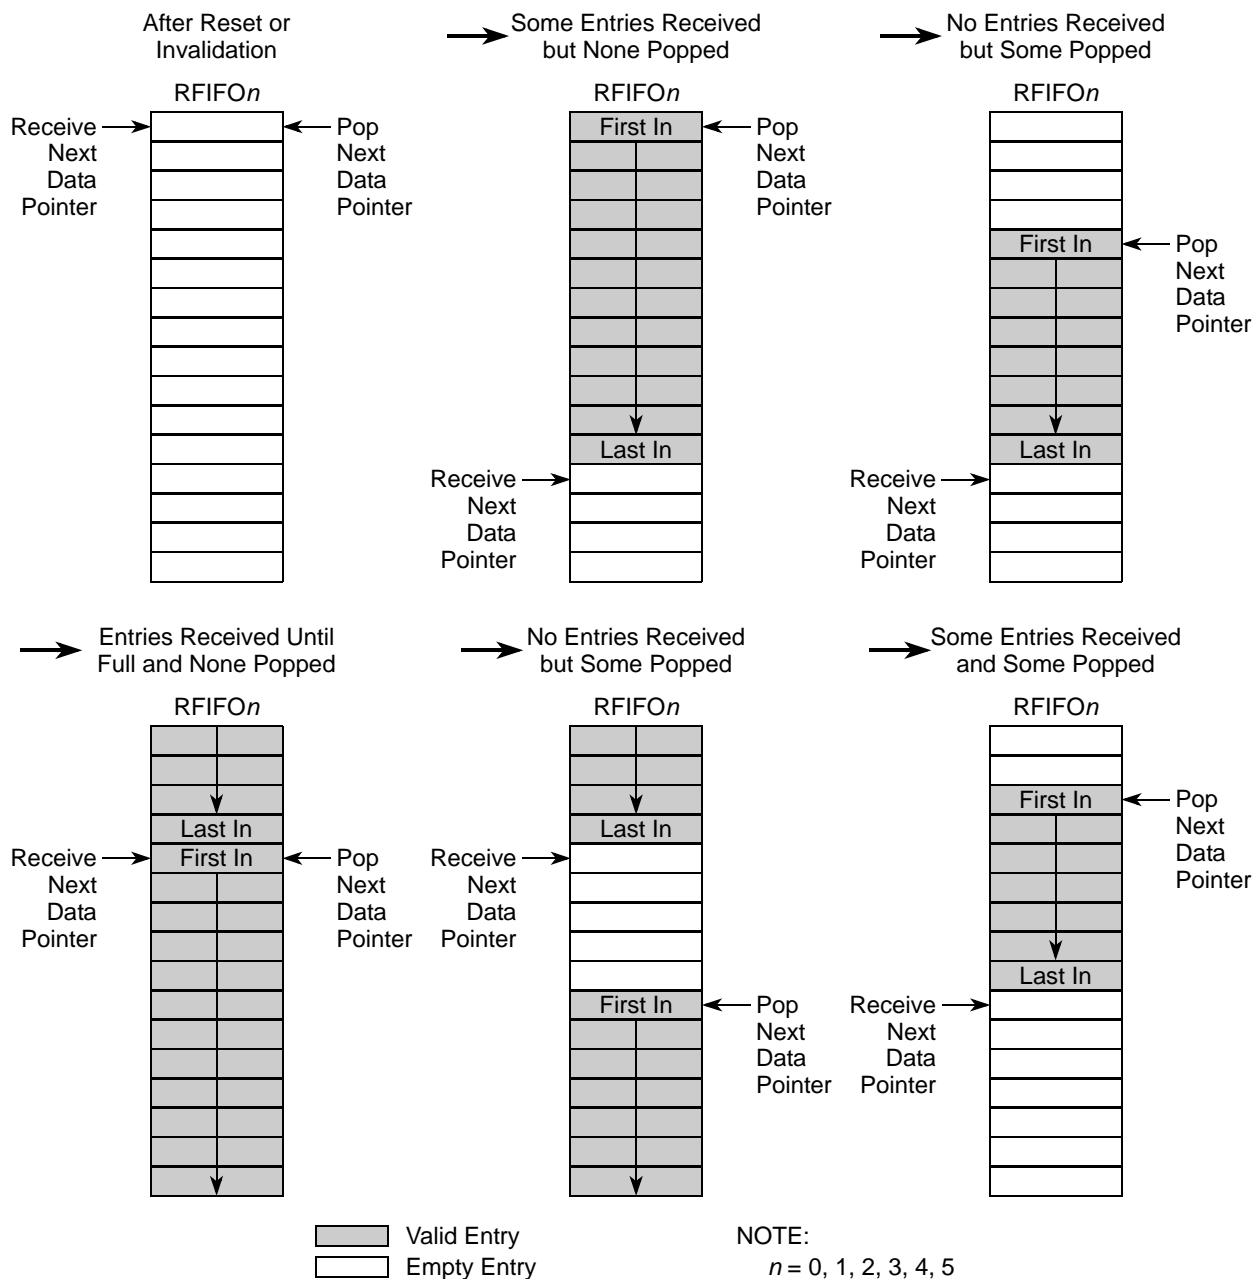

Figure 18-47. RFIFO Entry Pointer Example

18.4.4.2 Distributing Result Data into RFIFOs

Data to be moved into the RFIFOs can come from three sources: from ADC0, from ADC1, or from the external device. All result data comes with a MESSAGE_TAG field defining what should be done with the received data. The FIFO control unit decodes the MESSAGE_TAG field and:

- Stores the 16-bit data into the appropriate RFIFO if the MESSAGE_TAG indicates a valid RFIFO number or
- Ignores the data in case of a null or “reserved for customer use” MESSAGE_TAG

In general, received data is moved into RFIFOs as they become available, while an exception happens when multiple results from different sources become available at the same time. In that case, result data from ADC0 is processed first, result data from ADC1 is only processed after all ADC0 data is processed, and result data from the external device is only processed after all data from ADC0/1 is processed.

When time-stamped results return from the on-chip ADCs, the conversion result and the time stamp are always moved to the RFIFOs in consecutive clock cycles to guarantee they are always stored in consecutive RFIFO entries.

18.4.5 On-Chip ADC Configuration and Control

18.4.5.1 Enabling and Disabling the on-chip ADCs

The on-chip ADCs have an enable bit (ADC0_CR[ADC0_EN] and ADC1_CR[ADC1_EN], see [Section 18.3.3.1, “ADCn Control Registers \(ADC0_CR and ADC1_CR\)”](#)) which allows the enabling of the ADCs only when necessary. When the enable bit for an ADC is negated, the clock input to that ADC is stopped. The ADCs are disabled out of reset - ADC0/1_EN bits are negated - to allow for their safe configuration. The ADC must only be configured when its enable bit is negated. After the enable bit of an ADC is asserted, clock input is started, and the bias generator circuit is turned on. When the enable bits of both ADCs are negated, the bias circuit generator is stopped.

NOTE

Conversion commands sent to a disabled ADC are ignored by the ADC control hardware.

NOTE

An 8ms wait time from VDDA power up to enabling ADC is required to pre-charge the external 100nf capacitor on REFBYPC. This time must be guaranteed by the crystal startup time plus the reset duration, or the host application. The ADC internal bias generator circuit starts up after 10 μ s upon VRH/VRL power up and produces a stable/required bias current to the pre-charge circuit, but the current to the other analog circuits are disabled until ADCs are enabled. As soon as the ADCs are enabled, the bias currents to other analog circuits are ready.

NOTE

Because of previous design versions, the EQADC always waits 120 ADC clocks before issuing the first conversion command following the enabling of one of on-chip ADCs, or the exiting of stop mode. There are two independent counters checking for this delay: one clocked by ADC0_CLK and another by ADC1_CLK. Conversion commands can start to be executed whenever one of these counters completes counting 120 ADC clocks.

[NOTE TO MIKE GARRARD: the implication of this paragraph is that the two clocks are the ADC timebases. is this the case? (Mike Garrard, can you check this one out) can they be read, or even polled to see if 120 ADC clocks is finished?]

18.4.5.2 ADC Clock and Conversion Speed

The clock input to the ADCs is defined by setting the ADC0_CR[ADC0_CLK_PS] and ADC1_CR[ADC1_CLK_PS] fields. Refer to [Section 18.3.3.1, “ADCn Control Registers \(ADC0_CR and ADC1_CR\).”](#) The ADC0/1_CLK_PS field selects the clock divide factor by which the system clock is divided as showed in [Table 18-28](#). The ADC clock frequency is calculated as below and it must not exceed 12 MHz.

$$\text{ADCClockFrequency} = \frac{\text{SystemClockFrequency(MHz)}}{\text{SystemClockDivideFactor}}; (\text{ADCClockFrequency} \leq 12\text{MHz})$$

[Figure 18-48](#) depicts how the ADC clocks for ADC0 and ADC1 are generated.

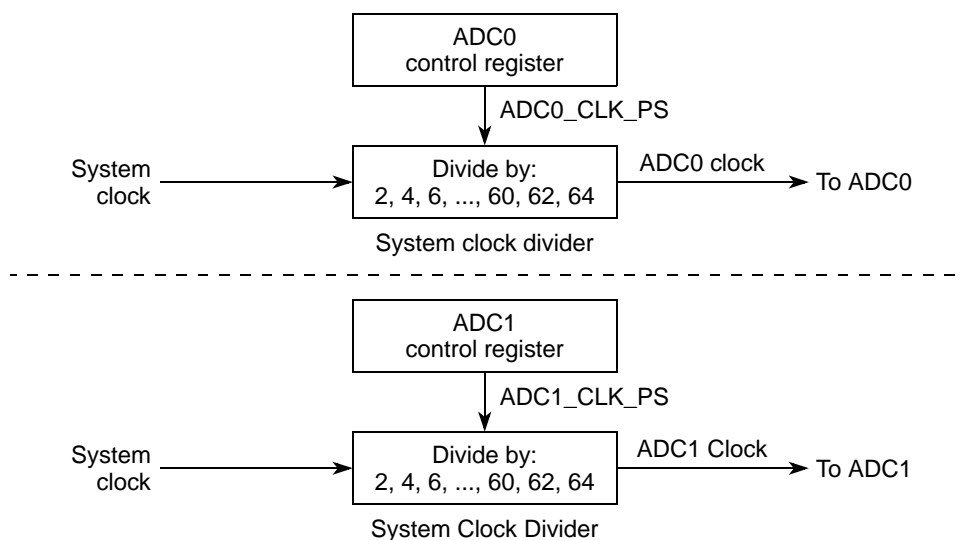

Figure 18-48. ADC0/1 Clock Generation

The ADC conversion speed (in kilosamples per second – ksamp/s) is calculated by the following formula. The number of sampling cycles is determined by the LST bits in the command message — see [Section , “Conversion Command Message Format for On-Chip ADC Operation,”](#) — and it can take one of the following values: 2, 8, 64, or 128 ADC clock cycles. The number of AD conversion cycles is 13 for differential conversions and 14 for single-ended conversions. The maximum conversion speed is achieved when the ADC Clock frequency is set to its maximum (12Mhz) and the number of sampling cycles set to its minimum (2 cycles). The maximum conversion speed for differential and single-ended conversions are 800ksamp/s and 750ksamp/s, respectively.

$$\text{ADCConversionSpeed} = \frac{\text{ADCClockFrequency(MHz)}}{(\text{NumberOfSamplingCycles} + \text{NumberOfADConversionCycles})}$$

[Table 18-47](#) shows an example of how the ADC0/1_CLK_PS can be set when using a 120 MHz system clock and the corresponding conversion speeds for all possible ADC clock frequencies. The table also shows that according to the system clock frequency, certain clock divide factors are invalid (2, 4, 6, 8 clock divide factors in the example) since their use would result in a ADC clock frequency higher than the maximum one supported by the ADC. ADC clock frequency must not exceed 12 Mhz.

Table 18-47. ADC Clock Configuration Example (System Clock Frequency = 120 MHz)

ADC0/1_CLK_PS[0:4]	System Clock Divide Factor	ADC Clock in MHz (System Clock = 120MHz)	Differential Conversion Speed with Default Sampling Time (13 + 2 cycles) in ksamp/s	Single-Ended Conversion Speed with Default Sampling Time (14 + 2 cycles) in ksamp/s

0b11110	62	1.94	129	121
0b11111	64	1.88	125	117

18.4.5.3 Time Stamp Feature

The on-chip ADCs can provide a time stamp for the conversions they execute. A time stamp is the value of the time base counter latched when the eQADC detects the end of the analog input voltage sampling. A time stamp for a conversion command is requested by setting the TSR bit in the corresponding command. When TSR is negated, that is a time stamp is not requested, the ADC returns a single result message containing the conversion result. When TSR is asserted, that is a time stamp is requested, the ADC returns two result messages; one containing the conversion result, and another containing the time stamp for that conversion. The result messages are sent in this order to the RFIFOs and both messages are sent to the same RFIFO as specified in the MESSAGE_TAG field of the executed conversion command.

The time base counter is a 16-bit up counter and wraps after reaching 0xFFFF. It is disabled after reset and it is enabled according to the setting of ADC_TSCR[TBC_CLK_PS] field (see [Section 18.3.3.2, “ADC Time Stamp Control Register \(ADC_TSCR\)”](#)). TBC_CLK_PS defines if the counter is enabled or disabled, and, if enabled, at what frequency it is incremented. The time stamps are returned regardless of whether the time base counter is enabled or disabled. The time base counter can be reset by writing 0x0000 to the ADC_TBCR ([Section 18.3.3.3, “ADC Time Base Counter Registers \(ADC_TBCR\)”](#)) with a write configuration command.

18.4.5.4 ADC Calibration Feature

18.4.5.4.1 Calibration Overview

The eQADC provides a calibration scheme to remove the effects of gain and offset errors from the results generated by the on-chip ADCs. Only results generated by the on-chip ADCs are calibrated. The results generated by ADCs on the external device are directly sent to RFIFOs unchanged. The main component of calibration hardware is a multiply-and-accumulate (MAC) unit, one per on-chip ADC, that is used to calculate the following transfer function which relates a calibrated result to a raw, uncalibrated one.

$$\text{CAL_RES} = \text{GCC} * \text{RAW_RES} + \text{OCC} + 2;$$

where:

- CAL_RES is the calibrated result corresponding the input voltage V_i .
- GCC is the gain calibration constant.
- RAW_RES is the raw, uncalibrated result corresponding to an specific input voltage V_i .
- OCC is the offset calibration constant.

- The addition of two reduces the maximum quantization error of the ADC. Refer to [Section 18.5.6.3, “Quantization Error Reduction During Calibration.”](#)

Calibration constants GCC and OCC are determined by taking two samples of known reference voltages and using these samples to calculate their values. For details and an example about how to calculate the calibration constants and use them in result calibration refer to [Section 18.5.6, “ADC Result Calibration.”](#) After it is calculated, GCC is stored in ADC0_GCCR and ADC1_GCCR (see [Section 18.3.3.4, “ADCn Gain Calibration Constant Registers \(ADC0_GCCR and ADC1_GCCR\)”](#)) and OCC in ADC0_OCCR and ADC1_OCCR (see [Section 18.3.3.5, “ADCn Offset Calibration Constant Registers \(ADC0_OCCR and ADC1_OCCR\)”](#)) from where their values are fed to the MAC unit. Since the analog characteristics of each on-chip ADC differs, each ADC has an independent pair of calibration constants.

A conversion result is calibrated according to the status of CAL bit in the command that initiated the conversion. If the CAL bit is asserted, the eQADC automatically calculates the calibrated result before sending the result to the appropriate RFIFO. If the CAL bit is negated, the result is not calibrated, it bypasses the calibration hardware, and is directly sent to the appropriate RFIFO.

18.4.5.4.2 MAC Unit and Operand Data Format

The MAC unit diagram is shown in [Figure 18-49](#). Each on-chip ADC has a separate MAC unit to calibrate its conversion results.

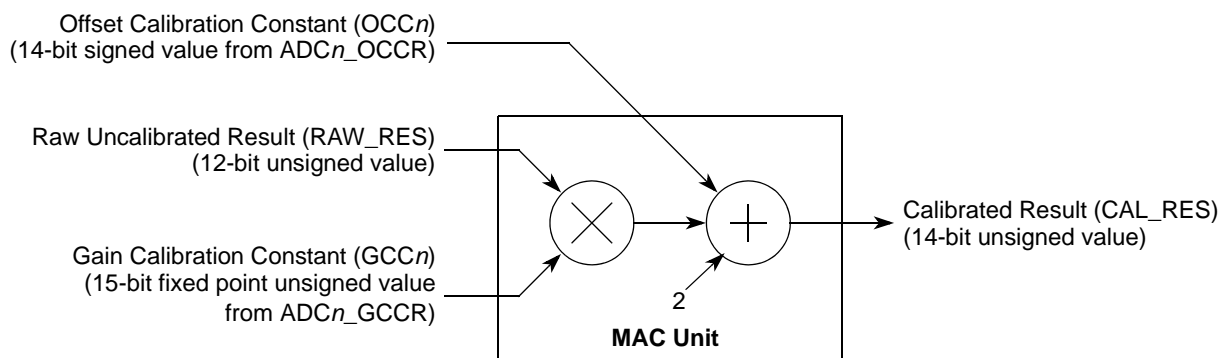

Figure 18-49. MAC Unit Diagram

The OCC_n operand is a 14-bit signed value and it is the upper 14 bits of the value stored in ADC0_OCCR and ADC1_OCCR. The RAW_RES operand is the raw uncalibrated result, and it is a direct output from the on-chip ADCs.

The GCC_n operand is a 15-bit fixed point unsigned value, and it is the upper 15 bits of the value stored in ADC0_GCCR and ADC1_GCCR. The GCC is expressed in the $GCC_INT.GCC_FRAC$ binary format. The integer part of the GCC ($GCC_INT = GCC[1]$) contains a single binary digit while its fractional part ($GCC_FRAC = GCC[2:15]$) contains 14 bits. Refer to [Figure 18-50](#) for more information. The gain constant equivalent decimal value ranges from 0 to 1.999938..., as shown in [Table 18-49](#). Two is always added to the MAC output: see [Section 18.5.6.3, “Quantization Error Reduction During Calibration.”](#) CAL_RES output is the calibrated result, and it is a 14-bit unsigned value. CAL_RES is truncated to 0x3FFF, in case of a overflow, and to 0x0000, in case of an underflow.

Figure 18-50. Gain Calibration Constant Format

Table 18-48. Gain Calibration Constant Format Field Descriptions

Field	Description
0	Reserved
1 GCC_INT[0]	Integer part of the gain calibration constant for ADC n . GCC_INT is the integer part of the gain calibration constant (GCC) for ADC0/1.
2–15 GCC_FRAC[1:14]	Fractional part of the gain calibration constant for ADC n . GCC_FRAC is the fractional part of the gain calibration constant (GCC) for ADC n . GCC_FRAC can express decimal values ranging from 0 to 0.999938...

18.4.5.5 ADC Control Logic Overview and Command Execution

Figure 18-51 shows the basic logic blocks involved in the ADC control and how they interact. CFIFOs/RFIFOs interact with ADC command/result message return logic through the FIFO control unit. The EB and BN bits in the command message uniquely identify the ADC to which a command should be sent. The FIFO control unit decodes these bits and sends the ADC command to the proper ADC. Other

blocks of logic are the result format and calibration submodule, the time stamp logic, and the MUX control logic.

The result format and calibration submodule formats the returning data into result messages and sends them to the RFIFOs. The returning data can be data read from an ADC register, a conversion result, or a time stamp. The formatting and calibration of conversion results also take place inside this submodule.

The time stamp logic latches the value of the time base counter when detecting the end of the analog input voltage sampling, and sends it to the result format and calibration submodule as time stamp information.

The MUX control logic generates the proper MUX control signals and, when the ADC0/1_EMUX bits are asserted, the MA signals based on the channel numbers extracted from the ADC Command.

ADC commands are stored in the ADC command buffers (2 entries) as they come in and they are executed on a first-in-first-out basis. After the execution of a command in ENTRY1 finishes, all commands are shifted one entry. After the shift, ENTRY0 is always empty and ready to receive a new command. Execution of configuration commands only starts when they reach ENTRY1. Consecutive conversion commands are pipelined, and their execution can start while in ENTRY0. This is explained below.

A/D conversion accuracy can be affected by the settling time of the input channel multiplexers. Some time is required for the channel multiplexer's internal capacitances to settle after the channel number is changed. If the time prior to and during sampling is not long enough to permit this settling, then the voltage on the sample capacitors do not accurately represent the voltage to be read. This is a problem in particular when external muxes are used.

To maximize settling time, when a conversion command is in buffer ENTRY1 and another conversion command is identified in ENTRY0, then the channel number of ENTRY0 is sent to the *MUX control logic* half an ADC clock before the start of the sampling phase of the command in ENTRY0. This pipelining of sample and settling phase is shown in [Figure 18-52\(b\)](#).

This provides more accurate sampling, which is specially important for applications that require high conversion speeds, i.e., with the ADC running at maximum clock frequency and with the analog input voltage sampling time set to a minimum (2 ADC clock cycles). In this case the short sampling time may not allow the multiplexers to completely settle. The second advantage of pipelining conversion commands is to provide equal conversion intervals even though the sample time increases on second and subsequent conversions. Refer to [Figure 18-52](#). This is important for any digital signal process application.

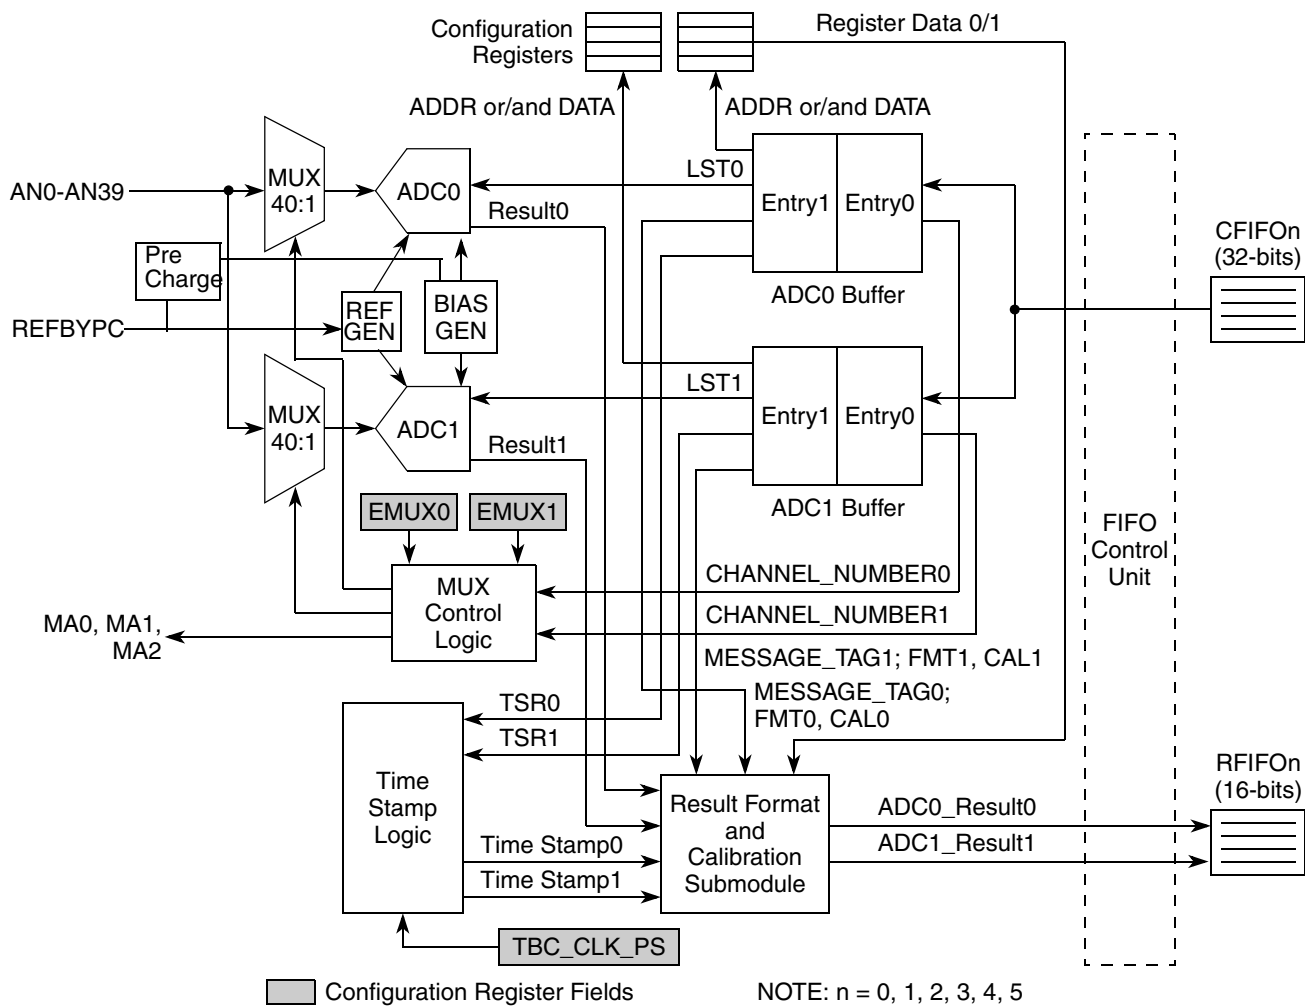

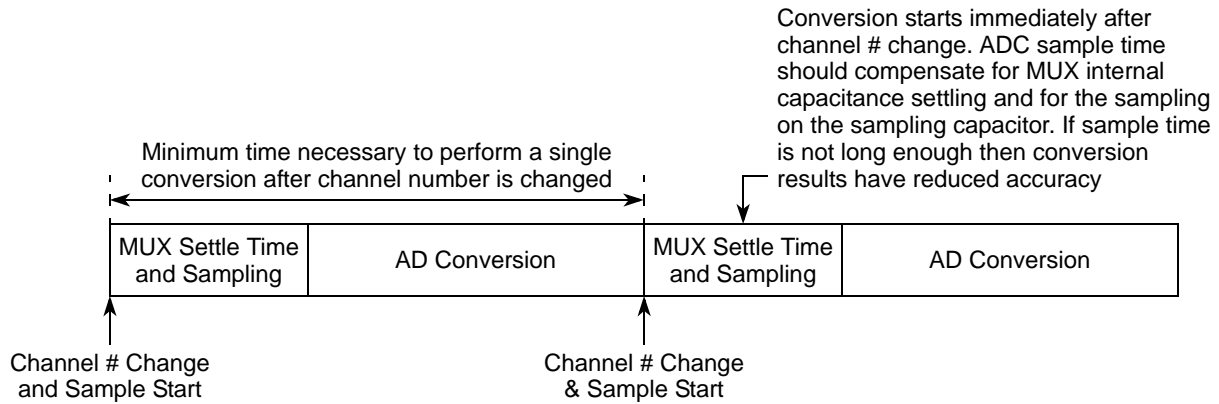

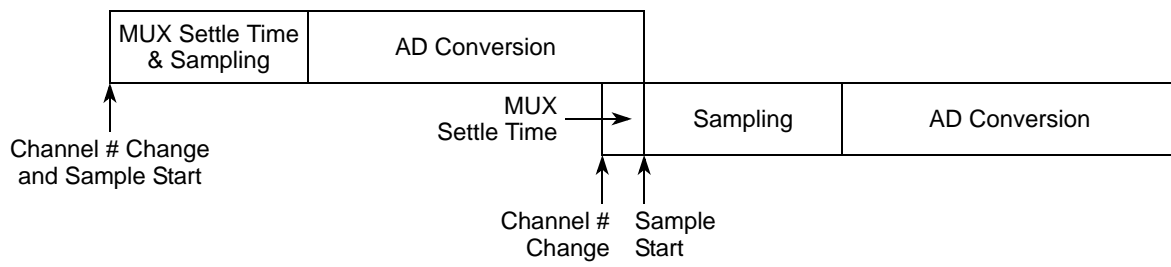

Figure 18-51. On-Chip ADC Control Scheme

(a) Command Execution Sequence for Two Non-Overlapped Commands

Channel # changes before sampling starts leading to more time for MUX internal capacitance to settle.

(b) Command Execution Sequence for Two Overlapped Commands

Figure 18-52. Overlapping Consecutive Conversion Commands

18.4.6 Internal/External Multiplexing

18.4.6.1 Channel Assignment

The internal analog multiplexers select one of the 40 analog input pins for conversion, based on the CHANNEL_NUMBER field of a Command Message. The analog input pin channel number assignments and the pin definitions vary depending on how the ADC0/1_EMUX are configured. Allowed combinations of ADC0/1_EMUX bits are shown in [Table 18-50](#) together with references to tables indicating how CHANNEL_NUMBER field of each conversion command must be set to avoid channel selection conflicts.

During differential conversions the analog multiplexer passes differential signals to both the positive and negative terminals of the ADC. The differential conversions can only be initiated on four channels: DAN0, DAN1, DAN2, and DAN3. Refer to [Table 18-51](#) and [Figure 18-52](#) for the channel numbers used to select differential conversions.

Table 18-50. ADC_n_EMUX Bits Combinations

ADC0_EMUX	ADC1_EMUX	CHANNEL_NUMBER should be set as in	
		ADC0	ADC1
0	0	Refer to Table 18-51	Refer to Table 18-51
0	1	Refer to Table 18-51	Refer to Table 18-51
1	0	Refer to Table 18-51	Refer to Table 18-51
1	1	Reserved ¹	

¹ ADC0_EMUX and ADC1_EMUX must not be asserted at the same time.

[Table 18-51](#) shows the channel number assignments for the non-multiplexed mode. The 40 single-ended channels and 4 differential pairs are shared between the two ADCs.

Table 18-51. Non-multiplexed Channel Assignments¹

Input Pins			Channel Number in CHANNEL_NUMBER Field	
Analog Pin Name	Other Functions	Conversion Type	Binary	Decimal
AN0 to AN39		Single-ended	0000_0000 to 0010_0111	0 to 39
VRH		Single-ended	0010_1000	40
VRL		Single-ended	0010_1001	41
	$(VRH - VRL)/2$ see footnote ²	Single-ended	0010_1010	42
	$75\% \times (VRH - VRL)$	Single-ended	0010_1011	43
	$25\% \times (VRH - VRL)$	Single-ended	0010_1100	44
Reserved			0010_1101 to 0101_1111	45 to 95
DAN0+ and DAN0- DAN1+ and DAN1- DAN2+ and DAN2- DAN3+ and DAN3-		Differential Differential Differential Differential	0110_0000 0110_0001 0110_0010 0110_0011	96 97 98 99
Reserved			0110_0100 to 1111_1111	100 to 255

¹ The two on-chip ADCs can access the same analog input pins but simultaneous conversions are not allowed. Also, when one ADC is performing a differential conversion on a pair of pins, the other ADC must not access either of these two pins as single-ended channels.

² This equation only applies before calibration. After calibration, the 50% reference point returns approximately 20mV lower than the expected 50% of the difference between the High Reference Voltage (V_{RH}) and the Low Reference Voltage (V_{RL}). For calibration of the ADC, only use the 25% and 75% points as described in [Section 18.5.6.1, "MAC Configuration Procedure"](#)

[Table 18-52](#) shows the channel number assignments for multiplexed mode. The ADC with the ADC_n_EMUX bit asserted can access 4 differential pairs, 39 single-ended, and, at most, 32 externally

multiplexed channels. Refer to [Section 18.4.6.2, “External Multiplexing,”](#) for a detailed explanation about how external multiplexing can be achieved.

Table 18-52. Multiplexed Channel Assignments¹

Input Pins			Channel Number in CHANNEL_NUMBER Field	
Analog Pin Name	Other Functions	Conversion Type	Binary	Decimal
AN0 to AN7		Single-ended	0000_0000 to 0000_0111	0 to 7
Reserved			0000_1000 to 0000_1011	8 to 11
AN12 to AN39		Single-ended	0000_1100 to 0010_0111	12 to 39
VRH		Single-ended	0010_1000	40
VRL		Single-ended	0010_1001	41
	(VRH–VRL)/2	Single-ended	0010_1010	42
	75% x (VRH–VRL)	Single-ended	0010_1011	43
	25% x (VRH–VRL)	Single-ended	0010_1100	44
Reserved			0010_1101 to 0011_1111	45 to 63
ANW	—	Single-ended	0100_0xxx	64 to 71
ANX	—	Single-ended	0100_1xxx	72 to 79
ANY	—	Single-ended	0101_0xxx	80 to 87
ANZ	—	Single-ended	0101_1xxx	88 to 95
DAN0+ and DAN0- DAN1+ and DAN1- DAN2+ and DAN2- DAN3+ and DAN3-		Differential Differential Differential Differential	0110_0000 0110_0001 0110_0010 0110_0011	96 97 98 99
Reserved			0011_0100 to 1111_1111	100 to 255

¹ The two on-chip ADCs can access the same analog input pins but simultaneous conversions are not allowed. Also, when one ADC is performing a differential conversion on a pair of pins, the other ADC must not access either of these two pins as single-ended channels.

18.4.6.2 External Multiplexing

The eQADC can use from one to four external multiplexers to expand the number of analog signals that may be converted. Up to 32 analog channels can be converted through external multiplexer selection. The externally multiplexed channels are automatically selected by the CHANNEL_NUMBER field of a command message, in the same way done with internally multiplexed channels. The software selects the external multiplexed mode by setting the ADC0/1_EMUX bit in either ADC0_CR or ADC1_CR depending on which ADC performs the conversion. [Figure 18-52](#) shows the channel number assignments for the multiplexed mode. There are 4 differential pairs, 40 single-ended, and, at most, 32 externally multiplexed channels that can be selected. Only one ADC can have its ADC0/1_EMUX bit asserted at a time.

[Figure 18-53](#) shows the maximum configuration of four external multiplexer chips connected to the eQADC. The external multiplexer chip selects one of eight analog inputs and connects it to a single analog

output, which is fed to a specific input of the eQADC. The eQADC provides three multiplexed address signals, MA0, MA1, and MA2, to select one of eight inputs. These three multiplexed address signals are connected to all four external multiplexer chips. The analog output of the four multiplexer chips are each connected to four separate eQADC inputs, ANW, ANX, ANY, and ANZ. The MA pins correspond to the three least significant bits of the channel number that selects ANW, ANX, ANY, and ANZ with MA0 being the most significant bit - Refer to [Table 18-53](#).

Table 18-53. Encoding of MA Pins¹

Channel Number selecting ANW, ANX, ANY, ANZ (decimal)				MA0	MA1	MA2
ANW	ANX	ANY	ANZ			
64	72	80	88	0	0	0
65	73	81	89	0	0	1
66	74	82	90	0	1	0
67	75	83	91	0	1	1
68	76	84	92	1	0	0
69	77	85	93	1	0	1
70	78	86	94	1	1	0
71	79	87	95	1	1	1

¹ 0 means pin is driven LOW and 1 that pin is driven HIGH.

When the external multiplexed mode is selected for either ADC, the eQADC automatically creates the MA output signals from CHANNEL_NUMBER field of a command message. The eQADC also converts the proper input channel (ANW, ANX, ANY, and ANZ) by interpreting the CHANNEL_NUMBER field. As a result, up to 32 externally multiplexed channels appear to the conversion queues as directly connected signals.

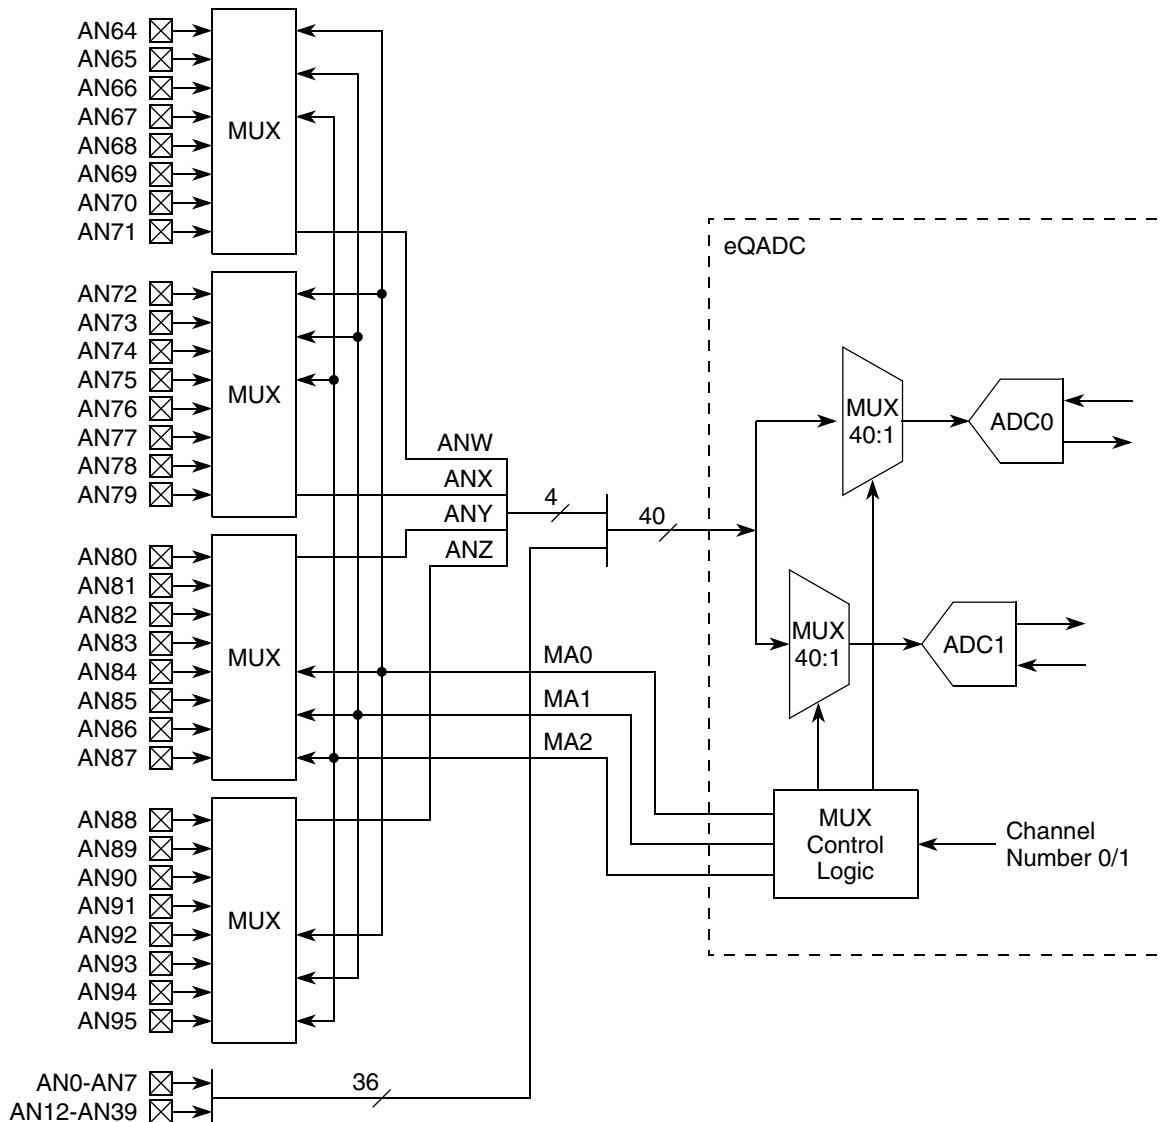

Figure 18-53. Example of External Multiplexing

18.4.7 eQADC eDMA/Interrupt Request

Table 18-54 lists methods to generate interrupt requests in the eQADC queuing control and triggering control. The eDMA/interrupt request select bits and the eDMA/interrupt enable bits are described in Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 (EQADC_IDCRn),” and the interrupt flag bits are described in Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 (EQADC_FISRn).” Table 18-54 depicts all interrupts and eDMA requests generated by the eQADC.

Table 18-54. eQADC FIFO Interrupt Summary¹

Interrupt	Condition	Clearing Mechanism
Non Coherency Interrupt	NCIE _n = 1 NCF _n = 1	Clear NCF _n bit by writing a 1 to the bit.
Trigger Overrun Interrupt ²	TORIE _n = 1 TORF _n = 1	Clear TORF _n bit by writing a 1 to the bit.
Pause Interrupt	PIE _n = 1 PF _n = 1	Clear PF _n bit by writing a 1 to the bit.
End of Queue Interrupt	EOQIE _n = 1 EOQF _n = 1	Clear EOQF _n bit by writing a 1 to the bit.
Command FIFO Underflow Interrupt ²	CFUIE _n = 1 CFUF _n = 1	Clear CFUF _n bit by writing a 1 to the bit.
Command FIFO Fill Interrupt	CFFE _n = 1 CFFS _n = 0 CFFF _n = 1	Clear CFFF _n bit by writing a 1 to the bit.
Result FIFO Overflow Interrupt ²	RFOIE _n = 1 RFOF _n = 1	Clear RFOF _n bit by writing a 1 to the bit.
Result FIFO Drain Interrupt	RFDE _n = 1 RFDS _n = 0 RFDF _n = 1	Clear RFDF _n bit by writing a 1 to the bit.

¹ For details refer to [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\),”](#) and [Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 \(EQADC_IDCRn\).”](#)

² Apart from generating an independent interrupt request for when a RFIFO overflow interrupt, a CFIFO underflow interrupt, and a CFIFO trigger overrun interrupt occurs, the eQADC also provides a combined interrupt request at which these requests from ALL CFIFOs are ORed. Refer to [Figure 18-54](#) for details.

[Table 18-55](#) describes a list of methods to generate eDMA requests by the eQADC.

Table 18-55. eQADC FIFO eDMA Summary¹

eDMA Request	Condition	Clearing Mechanism
Result FIFO Drain eDMA Request	RFDE _n = 1 RFDS _n = 1 RFDF _n = 1	The eQADC automatically clears the RFDF _n when RFIFOn becomes empty. Writing 1 to the RFDF _n bit is not allowed while RDFS = 1.
Command FIFO Fill eDMA Request	CFFE _n = 1 CFFS _n = 1 CFFF _n = 1	The eQADC automatically clears the CFFF _n when CFIFOn becomes full. Writing 1 to the CFFF _n bit is not allowed while CFDS = 1.

¹ For details refer to [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\),”](#) and [Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 \(EQADC_IDCRn\).”](#)

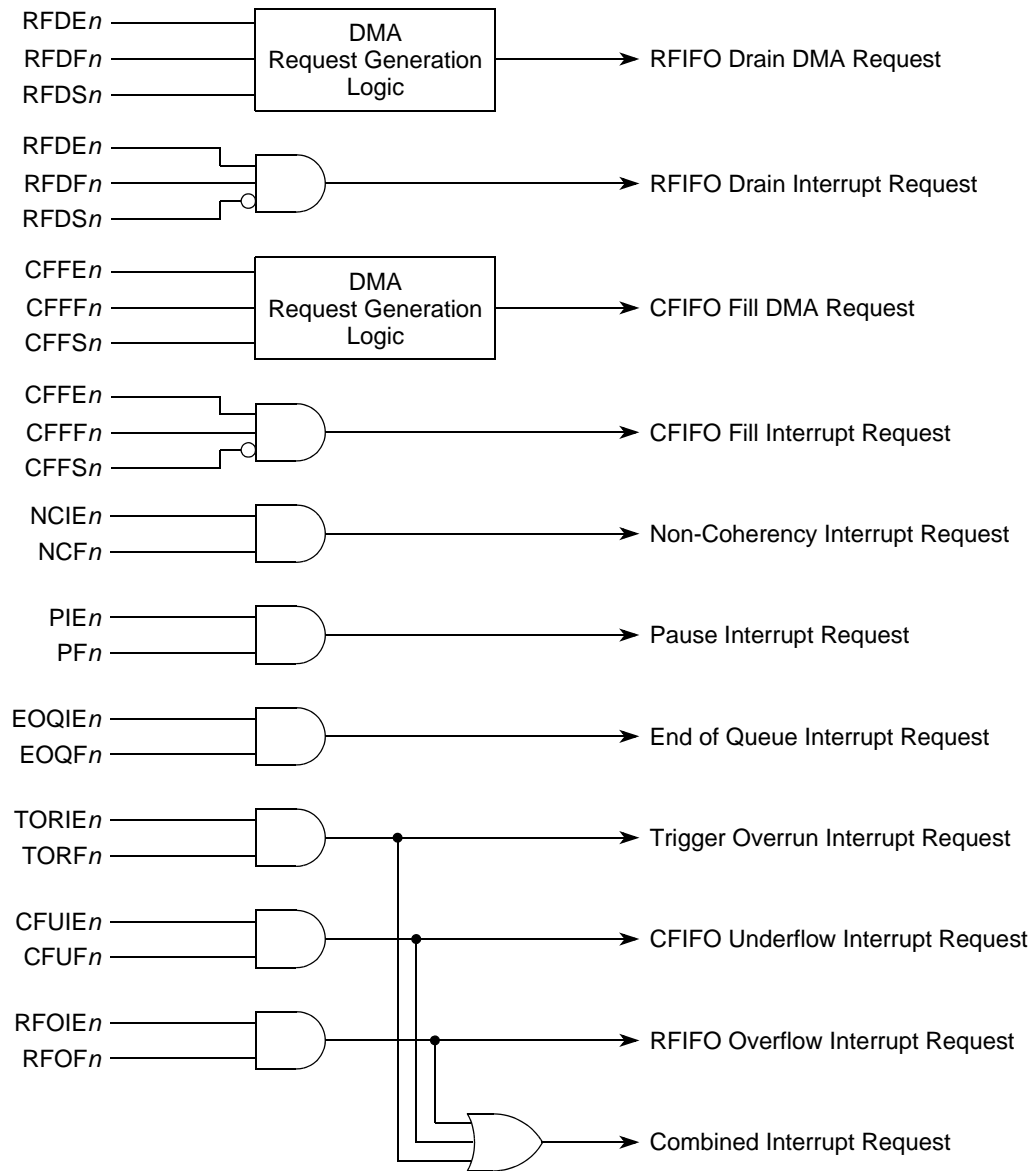

Figure 18-54. eQADC eDMA and Interrupt Requests

18.4.8 eQADC Synchronous Serial Interface (SSI) Submodule

Figure 18-55. eQADC Synchronous Serial Interface Block Diagram

The eQADC SSI protocol allows for a full duplex, synchronous, serial communication between the eQADC and a single external device. [Figure 18-55](#) shows the different components inside the eQADC SSI. The eQADC SSI submodule on the eQADC is always configured as a master. The eQADC SSI has four associated port pins:

- Free running clock (FCK)
- Serial data select ($\overline{\text{SDS}}$)
- Serial data in (SDI)
- Serial data out (SDO)

The FCK clock signal times the shifting and sampling of the two serial data signals and it is free running between transmissions, allowing it to be used as the clock for the external device. The $\overline{\text{SDS}}$ signal is asserted to indicate the start of a transmission, and negated to indicate the end or the abort of a transmission. SDI is the master serial data input and SDO the master serial data output.

The eQADC SSI submodule is enabled by setting the EQADC_MCR[ESSIE] (see [Section 18.3.2.1, “eQADC Module Configuration Register \(EQADC_MCR\)”](#)). When enabled, the eQADC SSI can be optionally capable of starting serial transmissions. When serial transmissions are disabled (ESSIE set to 0b10), no data is transmitted to the external device but FCK is free-running. This operation mode permits the control of the timing of the first serial transmission, and can be used to avoid the transmission of data to an unstable external device, for example, a device that is not fully reset. This mode of operation is specially important for the reset procedure of an external device that uses the FCK as its main clock.

The main elements of the eQADC SSI are the shift registers. The 26-bit transmit shift register in the master and 26-bit receive shift register in the slave are linked by the SDO pin. In a similar way, the 26-bit transmit shift register in the slave and 26-bit receive shift register in the master are linked by the SDI pin. Refer to

Figure 18-56. When a data transmission operation is performed, data in the transmit registers is serially shifted twenty-six bit positions into the receive registers by the FCK clock from the master; data is exchanged between the master and the slave. Data in the master transmit shift register in the beginning of a transmission operation becomes the output data for the slave, and data in the master receive shift register after a transmission operation is the input data from the slave.

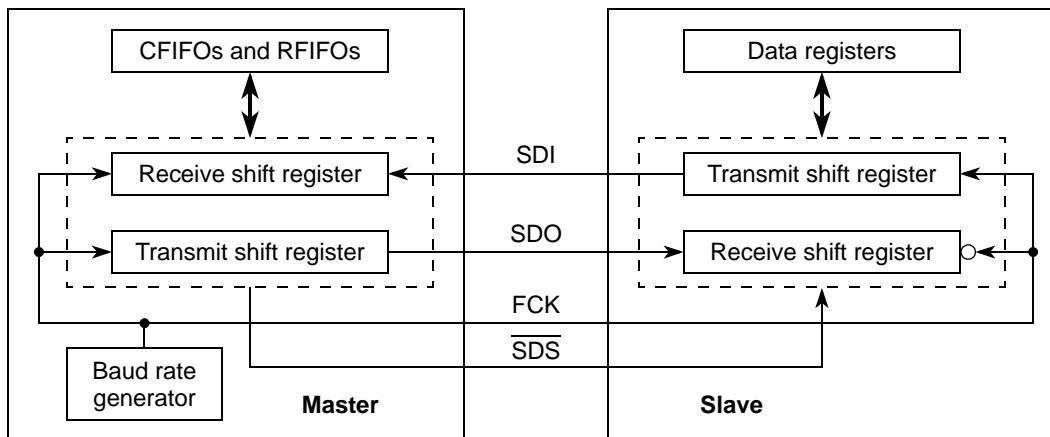

Figure 18-56. Full Duplex Pin Connection

18.4.8.1 eQADC SSI Data Transmission Protocol

Figure 18-57 shows the timing of an eQADC SSI transmission operation. The main characteristics of this protocol are the following:

- FCK is free running, it does not stop between data transmissions. FCK is driven low:
 - When the serial interface is disabled
 - In stop/debug mode
 - Immediately after reset
- Frame size is fixed to 26 bits.
- Msb bit is always transmitted first.
- Master drives data on the positive edge of FCK and latches incoming data on the next positive edge of FCK.
- Slave drives data on the positive edge of FCK and latches incoming data on the negative edge of FCK.

Master initiates a data transmission by driving \overline{SDS} low, and its msb bit on SDO on the positive edge of FCK. After an asserted \overline{SDS} is detected, the slave shifts its data out, one bit at a time, on every FCK positive edge. Both the master and the slave drive new data on the serial lines on every FCK positive edge. This process continues until all the initial 26-bits in the master shift register are moved into the slave shift register. t_{DT} is the delay between two consecutive serial transmissions, time during which \overline{SDS} is negated. When ready to start of the next transmission, the slave must drive the msb bit of the message on every positive edge of FCK regardless of the state of the \overline{SDS} signal. On the next positive edge, the second bit of the message is conditionally driven according to if an asserted \overline{SDS} was detected by the slave on the preceding FCK negative edge. This is an important requisite since the \overline{SDS} and the FCK are not

synchronous. The $\overline{\text{SDS}}$ signal is not generated by FCK, rather both are generated by the system clock, so that it is not guaranteed that FCK edges precede $\overline{\text{SDS}}$ edges. While $\overline{\text{SDS}}$ is negated, the slave continuously drives its msb bit on every positive edge of FCK until it detects an asserted $\overline{\text{SDS}}$ on the immediately next FCK negative edge. Refer to [Figure 18-58](#) for three situations showing how the slave should behave according to when $\overline{\text{SDS}}$ is asserted.

NOTE

On the master, the FCK is not used as a clock. Although, the eQADC SSI behavior is described in terms of the FCK positive and negative edges, all eQADC SSI related signals (SDI, SDS, SDO, and FCK) are synchronized by the system clock on the master side. There are no restrictions regarding the use of the FCK as a clock on the slave device.

18.4.8.1.1 Abort Feature

The master indicates it is aborting the current transfer by negating $\overline{\text{SDS}}$ before the whole data frame has been shifted out, that is the 26th bit of data being transferred has not been shifted out. The eQADC ignores the incompletely received message. The eQADC re-sends the aborted message whenever the corresponding CFIFO becomes again the highest priority CFIFO with commands bound for an external command buffer that is not full. Refer to [Section 18.4.3.2, “CFIFO Prioritization and Command Transfer,”](#) for more information on aborts and CFIFO priority.

18.4.8.2 Baud Clock Generation

As shown in [Figure 18-55](#), the baud clock generator divides the system clock to produce the baud clock. The EQADC_SSICR[BR] field (see [Section 18.3.2.12, “eQADC SSI Control Register \(EQADC_SSICR\)”](#)) selects the system clock divide factor as in [Table 18-21](#).¹

$$\text{BaudClockFrequency} = \frac{\text{SystemClockFrequency(MHz)}}{\text{SystemClockDivideFactor}}$$

1. Maximum FCK frequency is highly dependable on track delays, master pad delays, and slave pad delays.

NOTE:
 t_{MDT} = Minimum t_{DT} is programmable and defined in Section 18.3.2.12, 'eQADC SSI Control Register (EQADC_SSICR).'

18.4.9 Analog Submodule

18.4.9.1 Reference Bypass

The reference bypass capacitor (REFBYPC) signal requires a 100 nF capacitor connected to V_{RL} to filter noise on the internal reference used by the ADC.

Figure 18-59. Reference Bypass Circuit

18.4.9.2 Analog-to-Digital Converter (ADC)

18.4.9.2.1 ADC Architecture

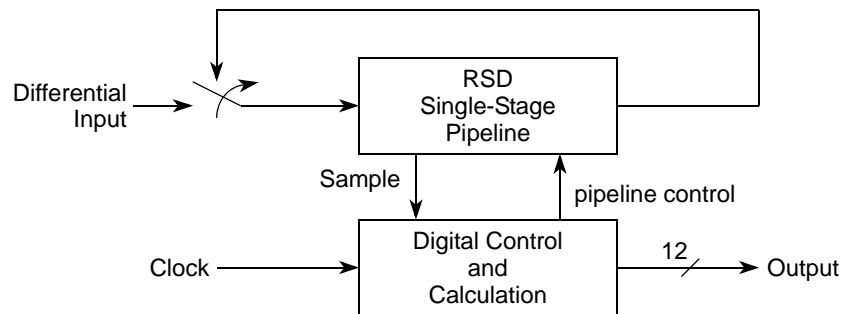

Figure 18-60. RSD ADC Block Diagram

The redundant signed digit (RSD) cyclic ADC consists of two main portions, the analog RSD stage, and the digital control and calculation module, as shown in [Figure 18-60](#). To begin an analog-to-digital conversion, a differential input is passed into the analog RSD stage. The signal is passed through the RSD stage, and then from the RSD stage output, back to its input to be passed again. To complete a 12-bit conversion, the signal must pass through the RSD stage 12 times. Each time an input signal is read into the RSD stage, a digital sample is taken by the digital control/calculation module. The digital control/calculation module uses this sample to tell the analog module how to condition the signal. The digital module also saves each successive sample and adds them according to the RSD algorithm at the end of the entire conversion cycle.

18.4.9.2.2 RSD Overview

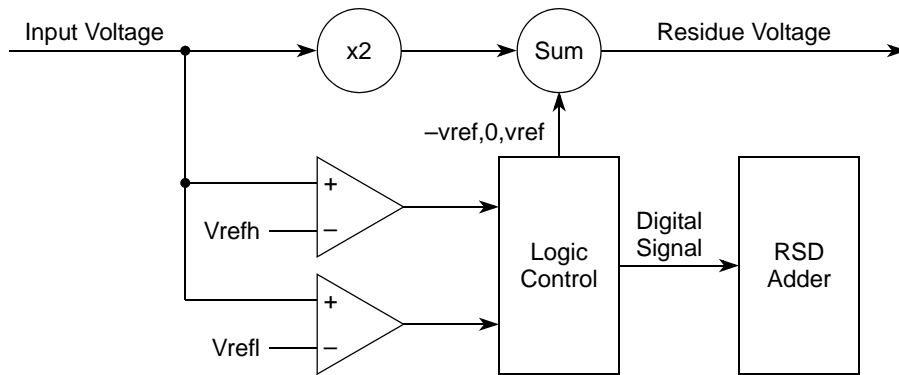

Figure 18-61. RSD Stage Block Diagram

On each pass through the RSD stage, the input signal are multiplied by exactly two, and summed with either $-v_{ref}$, 0, or v_{ref} , depending on the logic control. The logic control determines $-v_{ref}$, 0, or v_{ref} , depending on the two comparator inputs. As the logic control sets the summing operation, it also sends a digital value to the RSD adder. Each time an analog signal passes through the RSD single-stage, a digital value is collected by the RSD adder. At the end of an entire AD conversion cycle, the RSD adder uses these collected values to calculate the 12-bit digital output.

Figure 18-62 shows the transfer function for the RSD stage. Note how the digital value (AB) is dependent on the two comparator inputs.

Figure 18-62. RSD Stage Transfer Function

In each pass through the RSD stage, the remainder is sent back as the new input, and the digital signals, a and b, are stored. For the 12-bit ADC, the input signal is sampled during the input phase, and after each of the 12 passes through the RSD stage. Thus, 13 total a and b values are collected. Upon collecting all these

values, they are added according to the RSD algorithm to create the 12-bit digital representation of the original analog input. The bits are added in the following manner:

18.4.9.2.3 RSD Adder

The array, s1 to s12, are the digital output of the RSD ADC with s1 being the MSB (most significant bit) and s12 being the LSB (least significant bit).

Figure 18-63. RSD Adder

18.5 Initialization/Application Information

18.5.1 Multiple Queues Control Setup Example

This section provides an example of how to configure multiple user command queues. [Table 18-56](#) describes how each queue can be used for a different application. Also documented in this section are general guidelines on how to initialize the on-chip ADCs and the external device, and how to configure the command queues and the eQADC.

Table 18-56. Example Applications of Each Command Queue

Command Queue Number	Queue Type	Running Speed	Number of Contiguous Conversions	Example
0	Very fast burst time-based queue	every 2 μ s for 200 μ s; pause for 300 μ s and then repeat	2	Injector current profiling
1	Fast hardware-triggered queue	every 900 μ s	3	Current sensing of PWM controlled actuators
2	Fast repetitive time-based queue	every 2 ms	8	Throttle position
3	Software-triggered queue	every 3.9 ms	3	Command triggered by software strategy

Table 18-56. Example Applications of Each Command Queue (continued)

Command Queue Number	Queue Type	Running Speed	Number of Contiguous Conversions	Example
4	Repetitive angle-based queue	every 625 us	7	Airflow read every 30 degrees at 8000 RPM
5	Slow repetitive time-based queue	every 100 ms	10	Temperature sensors

18.5.1.1 Initialization of On-Chip ADCs/External Device

The following steps provide an example of configuring the eQADC to initialize the on-chip ADCs and the external device. In this example, commands are sent through CFIFO0.

1. Load all required configuration commands in the RAM in such way that they form a queue; this data structure is referred to below as Queue0. [Figure 18-64](#) shows an example of a command queue able to configure the on-chip ADCs and external device at the same time.
2. Configure [Section 18.3.2.2, “eQADC Null Message Send Format Register \(EQADC_NMSFR\).”](#)
3. Configure [Section 18.3.2.12, “eQADC SSI Control Register \(EQADC_SSICR\),”](#) to communicate with the external device.
4. Enable the eQADC SSI by programming the ESSIE field the [Section 18.3.2.1, “eQADC Module Configuration Register \(EQADC_MCR\).”](#)
 - a) Write 0b10 to ESSIE field to enable the eQADC SSI. FCK is free running but serial transmissions are not started.
 - b) Wait until the external device becomes stable after reset.
 - c) Write 0b11 to ESSIE field to enable the eQADC SSI to start serial transmissions.
5. Configure the eDMA to transfer data from Queue0 to CFIFO0 in the eQADC.
6. Configure [Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 \(EQADC_IDCRn\).”](#)
 - a) Set CFFS0 to configure the eQADC to generate an eDMA request to load commands from Queue0 to the CFIFO0.
 - b) Set CFFE0 to enable the eQADC to generate an eDMA request to transfer commands from Queue0 to CFIFO0; Command transfers from the RAM to the CFIFO0 starts immediately.
 - c) Set EOQIE0 to enable the eQADC to generate an interrupt after transferring all of the commands of Queue0 through CFIFO0.
7. Configure [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\).”](#)
 - a) Write 0b0001 to the MODE0 field in eQADC_CFCR0 to program CFIFO0 for software single-scan mode.
 - b) Write 1 to SSE0 to assert SSS0 and trigger CFIFO0.
8. Because CFIFO0 is in single-scan software mode and it is also the highest priority CFIFO, the eQADC starts to transfer configuration commands to the on-chip ADCs and to the external device.

9. When all of the configuration commands are transferred, EQADC_FISR_n[CF0] is set. Refer to [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISR_n\).”](#) The eQADC generates a end of queue interrupt. The initialization procedure is complete.

Command Queue in

	0x2	Configuration Command to ADC1—Ex: Write ADC1_CR
	0x3	Configuration Command to ADC2—Ex: Write to external device configuration register

Figure 18-64. Example of a Command Queue Configuring the On-Chip ADCs/External Device

18.5.1.2 Configuring eQADC for Applications

This section provides an example based on the applications in [Table 18-56](#). The example describes how to configure multiple command queues to be used for those applications and provides a step-by-step procedure to configure the eQADC and the associated command queue structures. In the example, the “Fast hardware-triggered command queue,” described on the second row of [Table 18-56](#), transfer its commands to ADC1; the conversion commands are executed by ADC1. The generated results are returned to RFIFO3 before being transferred to the result queues in the RAM by the eDMA.

NOTE

There is no fixed relationship between CFIFOs and RFIFOs with the same number. The results of commands being transferred through CFIFO1 can be returned to any RFIFO, regardless of its number. The destination of a result is determined by the MESSAGE_TAG field of the command that requested the result. Refer to [Section 18.4.1.2, “Message Format in eQADC,”](#) for details.

Step One: Set up the command queues and result queues.

1. Load the RAM with configuration and conversion commands. [Table 18-57](#) is an example of how command queue 1 commands should be set.
 - a) Each trigger event causes four commands to be executed. When the eQADC detects the pause bit asserted, it waits for another trigger to restart transferring commands from the CFIFO.
 - b) At the end of the command queue, the “EOQ” bit is asserted as shown in [Table 18-57](#).
 - c) Results are returned to RFIFO3 as specified in the MESSAGE_TAG field of commands.
2. Reserve memory space for storing results.

Table 18-57. Example of Command Queue Commands¹

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CFIFO header
ADC command

¹ Fields LST, TSR, FMT, and CHANNEL_NUMBER are not shown for clarity. Refer to [Section , “Conversion Command Message Format for On-Chip ADC Operation,”](#) for details.

² MESSAGE_TAG field is only defined for read configuration commands.

Step Two: Configure the eDMA to handle data transfers between the command/result queues in RAM and the CFIFOs/RFIFOs in the eQADC.

1. For transferring, set the source address of the eDMA TCD_n to point to the start address of command queue 1. Set the destination address of the eDMA to point to EQADC_CFPR1. Refer to [Section 18.3.2.4, “eQADC CFIFO Push Registers 0–5 \(EQADC_CFPRn\).”](#)
2. For receiving, set the source address of the eDMA TCD_n to point to EQADC_RFPR3. Refer to [Section 18.3.2.5, “eQADC Result FIFO Pop Registers 0–5 \(EQADC_RFPRn\).”](#) Set the destination address of the eDMA to point to the starting address of result queue 1.

Step Three: Configure the eQADC control registers.

1. Configure [Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 \(EQADC_IDCRn\).”](#)
 - a) Set EOQIE1 to enable the End of Queue Interrupt request.
 - b) Set CFFS1 and RFDS3 to configure the eQADC to generate eDMA requests to push commands into CFIFO1 and to pop result data from RFIFO3.
 - c) Set CFINV1 to invalidate the contents of CFIFO1.
 - d) Set RFDE3 and CFFE1 to enable the eQADC to generate eDMA requests. Command transfers from the RAM to the CFIFO1 starts immediately.
 - e) Set RFOIE3 to indicate if RFIFO3 overflows.
 - f) Set CFUIE1 to indicate if CFIFO1 underflows.
2. Configure MODE1 to continuous-scan rising edge external trigger mode in [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\).”](#)

Step Four: Command transfer to ADCs and result data reception.

When an external rising edge event occurs for CFIFO1, the eQADC automatically begins transferring commands from CFIFO1 when it becomes the highest priority CFIFO trying to send commands to ADC1. The received results are placed in RFIFO3 and then moved to result queue 1 by the eDMA.

18.5.2 eQADC/eDMA Controller Interface

This section provides an overview of the eQADC/eDMA interface and general guidelines about how the eDMA should be configured in order for it to correctly transfer data between the queues in system memory and the eQADC FIFOs.

18.5.2.1 Command Queue/CFIFO Transfers

In transfers involving command queues and CFIFOs, the eDMA moves data from a queued source to a single destination as shown in [Figure 18-65](#).

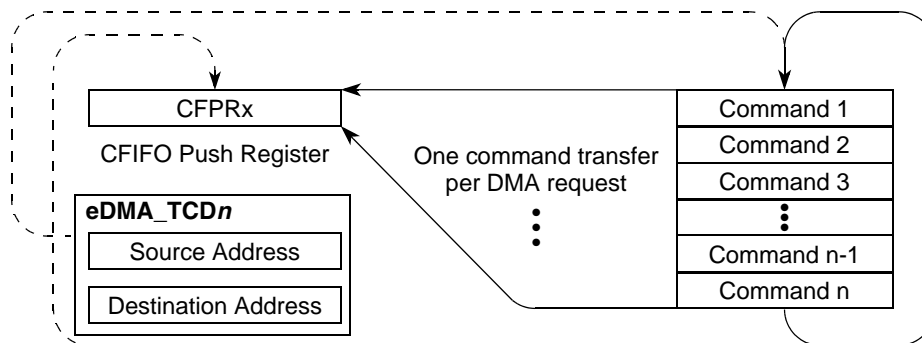

Figure 18-65. Command Queue/CFIFO Interface

The location of the data to be moved is indicated by the source address, and the final destination for that data, by the destination address. The eDMA has transfer control descriptors (TCDs) containing these addresses and other parameters used in the control of data transfers.

Refer to [Section 9.2.2.16, “Transfer Control Descriptor \(TCD\)”](#) for more information.

For every eDMA request issued by the eQADC, the eDMA must be configured to transfer a single command (32-bit data) from the command queue, pointed to by the source address, to the CFIFO push register, pointed to by the destination address. After the service of an eDMA request is completed, the source address has to be updated to point to the next valid command. The destination address remains unchanged. When the last command of a queue is transferred, do one of the following:

- Disable the eDMA channel. This might be desirable for CFIFOs in single scan mode.
- Update the source address to point to a valid command for the first command in the queue was transferred (cyclic queue), or the first command of any other command queue. This is desirable for CFIFOs in continuous scan mode, or in some cases, for CFIFOs in single-scan mode.

Refer to [Chapter 9, “Enhanced Direct Memory Access \(eDMA\)”](#) for details about how this functionality is supported.

18.5.2.2 Receive Queue/RFIFO Transfers

In transfers involving receive queues and RFIFOs, the eDMA controller moves data from a single source to a queue destination as shown in [Figure 18-66](#). The location of the data to be moved is indicated by the source address, and the final destination for that data, by the destination address. For every eDMA request issued by the EQADC, the eDMA controller has to be configured to transfer a single result (16-bit data), pointed to by the source address, from the RFIFO pop register to the receive queue, pointed to by the destination address. After the service of an eDMA request is completed, the destination address has to be updated to point to the location where the next 16-bit result are stored. The source address remains unchanged. When the last expected result is written to the receive queue, do one of the following:

- Disable the eDMA channel.
- Update the destination address to point to the next location where in-coming results are stored: the first entry of the current receive queue (cyclic queue); or the beginning of a new receive queue.

Refer to [Chapter 9, “Enhanced Direct Memory Access \(eDMA\)”](#) for details about how this functionality is supported.

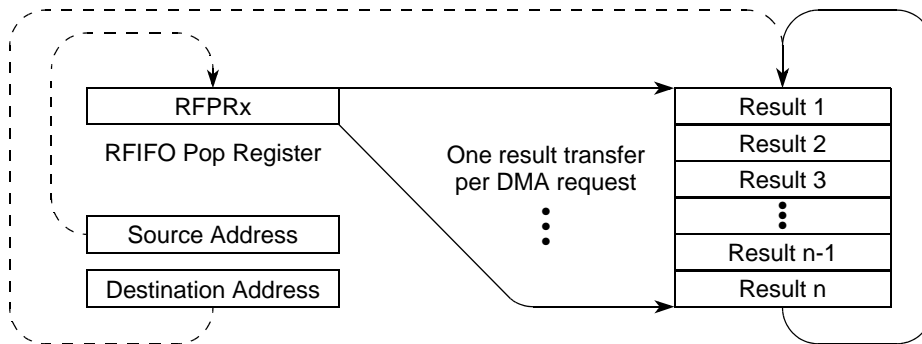

Figure 18-66. Receive Queue/RFIFO Interface

18.5.3 Sending Immediate Command Setup Example

In the eQADC, there is no immediate command register for sending a command immediately after writing to that register. However, a CFIFO can be configured to perform the same function as an immediate command register. The following steps illustrate how to configure CFIFO5 as an immediate command CFIFO. This eliminates the use of the eDMA. The results are returned to RFIFO5.

1. Configure the [Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 \(EQADC_IDCRn\).”](#)
 - a) Clear CFIFO fill enable5 (CFFE5 = 0) in EQADC_IDCR5.
 - b) Clear CFIFO underflow interrupt enable5 (CFUIE5 = 0) in EQADC_IDCR2.
 - c) Clear RFDS5 to configure the eQADC to generate interrupt requests to pop result data from RFIFO5.
 - d) Set RFIFO drain enable5 (RFDE5 = 1) in EQADC_IDCR5.
2. Configure the [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\).”](#)
 - a) Write 1 to CFINV5 in EQADC_CFCR5. This invalidates the contents of CFIFO5.
 - a) Set MODE5 to continuous-scan software trigger mode in EQADC_CFCR5.
3. To transfer a command, write it to the eQADC CFIFO push register 5 (EQADC_CFPR5) with message tag = 0b0101. Refer to [Section 18.3.2.4, “eQADC CFIFO Push Registers 0–5 \(EQADC_CFPRn\).”](#)
4. Up to 4 commands can be queued in CFIFO5. Check the CFCTR5 status in EQADC_FISR5 before pushing another command to avoid overflowing the CFIFO. Refer to [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\).”](#)
5. When the eQADC receives a conversion result for RFIFO5, it generates an interrupt request. RFIFO pop register 5 (EQADC_RFPR5) can be popped to read the result. Refer to [Section 18.3.2.5, “eQADC Result FIFO Pop Registers 0–5 \(EQADC_RFPRn\).”](#)

18.5.4 Modifying Queues

More command queues may be needed than the six supported by the eQADC. These additional command queues can be supported by interrupting command transfers from a configured CFIFO, even if it is triggered and transferring, modifying the corresponding command queue in the RAM or associating another command queue to it, and restarting the CFIFO. More details on disabling a CFIFO are described in [Section 18.4.3.5.1, “Disabled Mode.”](#)

1. Determine the resumption conditions when later resuming the scan of the command queue at the point before it was modified.
 - a) Change EQADC_CFCRn[MODEn] (see [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\)”](#)) to disabled. Refer to [Section 18.4.3.5.1, “Disabled Mode,”](#) for a description of what happens when MODEn is changed to disabled.
 - b) Poll EQADC_CFSR[CFSn] until it becomes IDLE (see [Section 18.3.2.11, “eQADC CFIFO Status Register \(EQADC_CFSR\)”](#)).

- c) Read and save EQADC_CFTCRn[TC_CFn] (see [Section 18.3.2.9, “eQADC CFIFO Transfer Counter Registers 0–5 \(EQADC_CFTCRn\)”](#)) for later resuming the scan of the queue. The TC_CFn provides the point of resumption.
 - d) Since all result data may not have been stored in the appropriate RFIFO at the time MODEn is changed to disable, wait for all expected results to be stored in the RFIFO/result queue before reconfiguring the eDMA to work with the modified result queue. The number of results that must return can be estimated from the TC_CFn value obtained above.
2. Disable the eDMA from responding to the eDMA request generated by EQADC_FISRn[CFFFn] and EQADC_FISRn[RFDFn] (see [Section 18.3.2.8, “eQADC FIFO and Interrupt Status Registers 0–5 \(EQADC_FISRn\)”](#)).
 3. Write “0x0000” to the TC_CFn field.
 4. Load the new configuration and conversion commands into RAM. Configure the eDMA to support the new command/result queue, but do not configure it yet to respond to eDMA requests from CFIFOn/RFIFOn.
 5. If necessary, modify the EQADC_IDCRn registers (see [Section 18.3.2.7, “eQADC Interrupt and eDMA Control Registers 0–5 \(EQADC_IDCRn\)”](#)) to suit the modified command queue.
 6. Write 1 to EQADC_CFCRn[CFINVn] (see [Section 18.3.2.6, “eQADC CFIFO Control Registers 0–5 \(EQADC_CFCRn\)”](#)) to invalidate the entries of CFIFOn.
 7. Configure the eDMA to respond to eDMA requests generated by CFFFn and RFDFn.
 8. Change MODEn to the modified CFIFO operation mode. Write 1 to SSEn to trigger CFIFOn if MODEn is software trigger.

18.5.5 Command Queue and Result Queue Usage

Figure 18-67 is an example of command queue and result queue usage. It shows the command queue 0 commands requesting results that are stored in result queue 0 and result queue 1, and command queue 1 commands requesting results that are stored only in result queue 1. Some command messages request data to be returned from the on-chip ADC/external device, but some only configure them and do not request returning data. When a command queue contains both write and read commands like command queue 0, the command queue and result queue entries are not aligned, in Figure 18-67, the result for the second command of command queue 0 is the first entry of result queue 0. The figure also shows that command queue and result queue entries can also become unaligned even if all commands in a command queue request data as command queue 1. Command queue 1 entries became unaligned to result queue 1 entries because a result requested by the fourth command queue 0 command was sent to result queue 1. This happens because the system can be configured so that several command queues can have results sent to a single result queue.

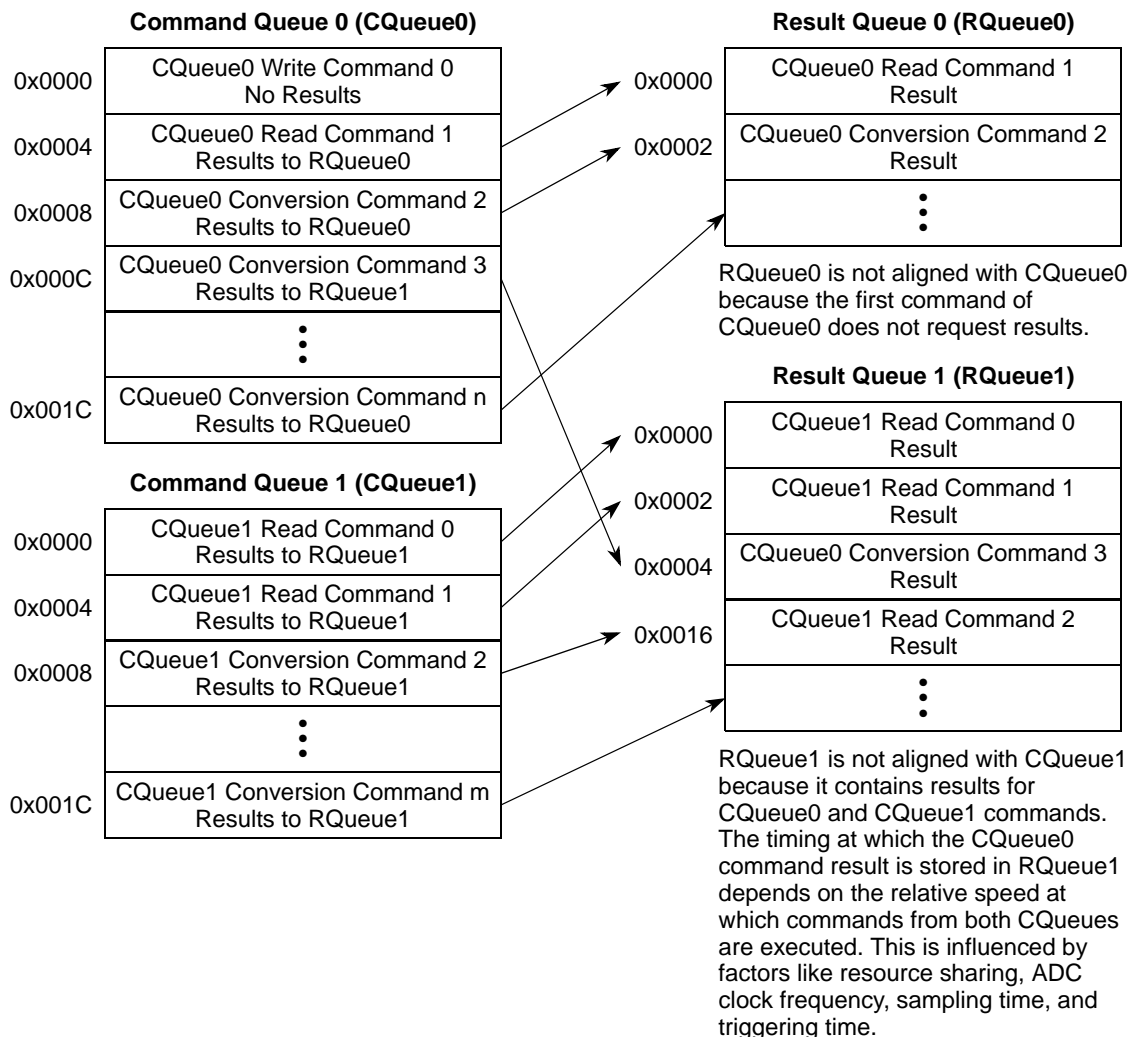

Figure 18-67. eQADC Command and Result Queues

18.5.6 ADC Result Calibration

The ADC result calibration process consists of two steps: determining the gain and offset calibration constants, and calibrating the raw results generated by the on-chip ADCs by solving the following equation discussed in [Section 18.4.5.4.1, “Calibration Overview.”](#)

$$CAL_RES = GCC * RAW_RES + OCC + 2; \tag{Eqn. 18-1}$$

The calibration constants GCC and OCC can be calculated from [Equation 18-1](#) provided that two pairs of expected (CAL_RES) and measured (RAW_RES) result values are available for two different input voltages. Most likely calibration points to be used are 25% VREF¹ and 75% VREF since they are far apart but not too close to the end points of the full input voltage range. This allows for calculations of more representative calibration constants. The eQADC provides these voltages via channel numbers 43 and 44.

1. VREF=V_{RH}-V_{RL}

The raw, uncalibrated results for these input voltages are obtained by converting these channels with conversion commands that have the CAL bit negated.

The transfer equations for when sampling these reference voltages are:

$$\text{CAL_RES75\%VREF} = \text{GCC} * \text{RAW_RES75\%VREF} + \text{OCC} + 2; \quad \text{Eqn. 18-2}$$

$$\text{CAL_RES25\%VREF} = \text{GCC} * \text{RAW_RES25\%VREF} + \text{OCC} + 2; \quad \text{Eqn. 18-3}$$

Thus;

$$\text{GCC} = (\text{CAL_RES75\%VREF} - \text{CAL_RES25\%VREF}) / (\text{RAW_RES75\%VREF} - \text{RAW_RES25\%VREF}); \quad \text{Eqn. 18-4}$$

$$\text{OCC} = \text{CAL_RES75\%VREF} - \text{GCC} * \text{RAW_RES75\%VREF} - 2; \quad \text{Eqn. 18-5}$$

or

$$\text{OCC} = \text{CAL_RES25\%VREF} - \text{GCC} * \text{RAW_RES25\%VREF} - 2; \quad \text{Eqn. 18-6}$$

After being calculated, the GCC and OCC values must be written to ADC0_GCCR and ADC1_GCCR registers (see [Section 18.3.3.4, “ADCn Gain Calibration Constant Registers \(ADC0_GCCR and ADC1_GCCR\)”](#)) and the ADC0_OCCR and ADC1_OCCR registers (see [Section 18.3.3.5, “ADCn Offset Calibration Constant Registers \(ADC0_OCCR and ADC1_OCCR\)”](#)) using write configuration commands.

The eQADC automatically calibrates the results, according to [Equation 18-1](#), of every conversion command that has its CAL bit asserted using the GCC and OCC values stored in the ADC calibration registers.

18.5.6.1 MAC Configuration Procedure

The following steps illustrate how to configure the calibration hardware, that is, determining the values of the gain and offset calibration constants, and the writing these constants to the calibration registers. This procedure should be performed for both ADC0 and ADC1.

1. Convert channel 44 with a command that has its CAL bit negated and obtain the raw, uncalibrated result for 25% VREF (RAW_RES_{25%VREF}).
2. Convert channel 43 with a command that has its CAL bit negated and obtain the raw, uncalibrated result for 75% VREF (RAW_RES_{75%VREF}).
3. Because the expected values for the conversion of these voltages are known (CAL_RES_{25%VREF} and CAL_RES_{75%VREF}), GCC and OCC values can be calculated from [Equation 18-4](#) and [Equation 18-5](#) using these values, and the results determined in steps 1 and 2.
4. Reformat GCC and OCC to the proper data formats as specified in [Section 18.4.5.4.2, “MAC Unit and Operand Data Format.”](#) GCC is an unsigned 15-bit fixed point value and OCC is a signed 14-bit value.

- Write the GCC value to ADCn gain calibration registers (see Section Section 18.3.3.4, “ADCn Gain Calibration Constant Registers (ADC0_GCCR and ADC1_GCCR)”) and the OCC value to ADCn offset calibration constant registers (see Section Section 18.3.3.5, “ADCn Offset Calibration Constant Registers (ADC0_OCCR and ADC1_OCCR)”) using write configuration commands.

18.5.6.2 Example Calculation of Calibration Constants

The raw results obtained when sampling reference voltages 25% VREF and 75% VREF were, respectively, 3798 and 11592. The results that should have been obtained from the conversion of these reference voltages are, respectively, 4096 and 12288. Therefore, using Equation 18-4 and Equation 18-5, the gain and offset calibration constants are:

$$GCC = (12288 - 4096) / (11592 - 3798) = 1.05106492 \rightarrow 1.05102539^1 = 0x4344$$

$$OCC = 12288 - 1.05106492 * 11592 - 2 = 102.06 \rightarrow 102 = 0x0066$$

Table 18-58 shows, for this particular case, examples of how the result values change according to GCC and OCC when result calibration is executed (CAL=1) and when it is not (CAL=0).

Table 18-58. Calibration Example

Input Voltage	Raw result (CAL=0)		Calibrated result (CAL=1)	
	Hexadecimal	Decimal	Hexadecimal	Decimal
25% VREF	0x0ED6	3798	0x1000	4095.794
75% VREF	0x2D48	11592	0x3000	12287.486

18.5.6.3 Quantization Error Reduction During Calibration

Figure 18-68 shows how the ADC transfer curve changes due to the addition of two to the MAC output during the calibration - see MAC output equation in Section 18.4.5.4, “ADC Calibration Feature.” The maximum absolute quantization error is reduced by half leading to an increase in accuracy.

1. This calculation is rounded down due to binary approximation.

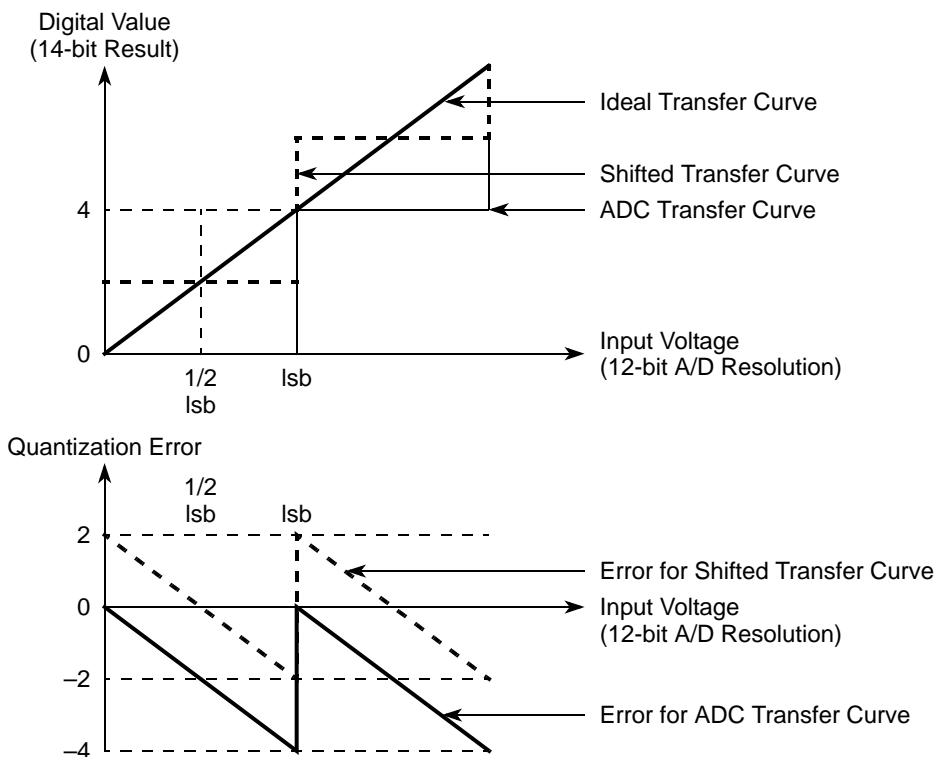

Figure 18-68. Quantization Error Reduction During Calibration

18.5.7 eQADC versus QADC

This section describes how the eQADC upgrades the QADC functionality. The section also provides a comparison between the eQADC and QADC in terms of their functionality. This section targets users familiar with terminology in QADC.

Figure 18-69 is an overview of a QADC.

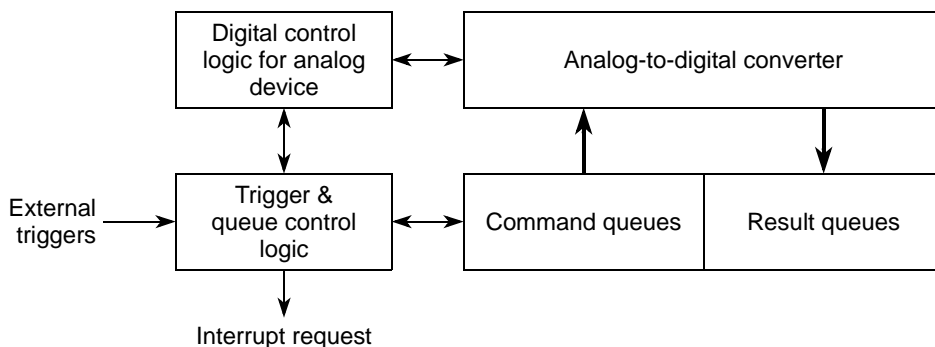

Figure 18-69. QADC Overview

Figure 18-70 is an overview of the eQADC system.

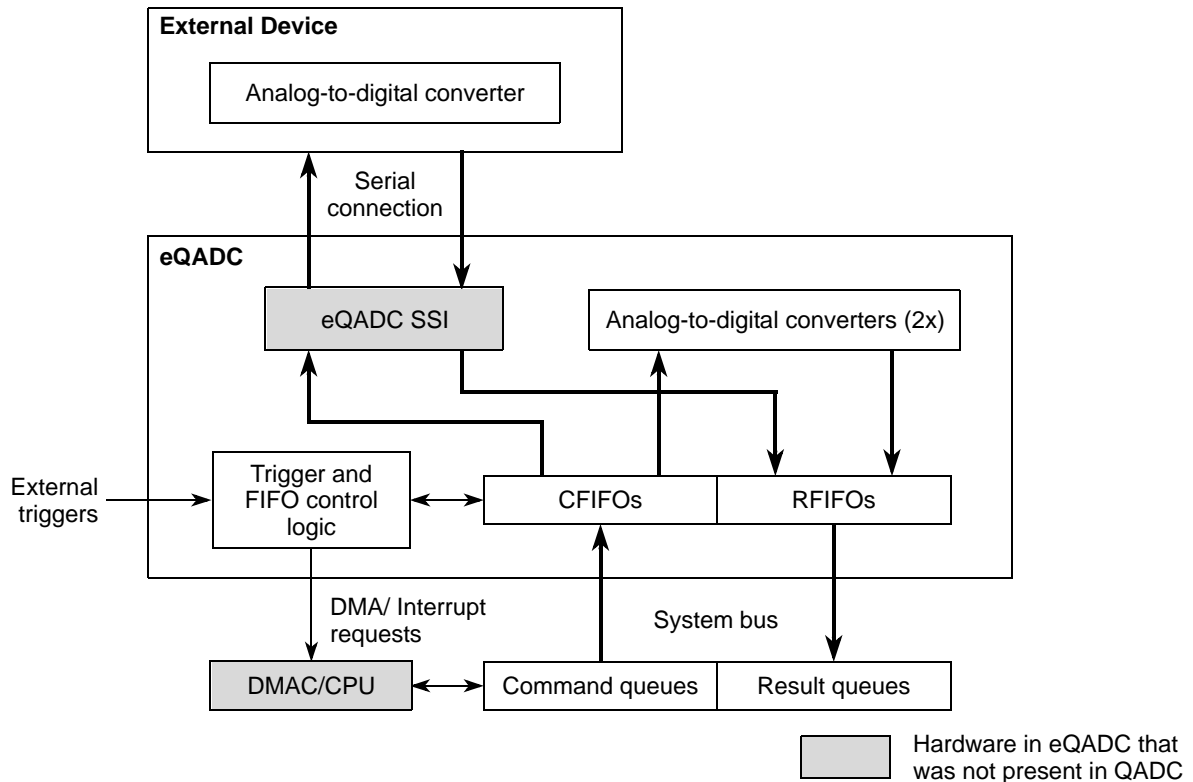

Figure 18-70. eQADC System Overview

The eQADC system consists of four parts: queues in system memory, the eQADC, on-chip ADCs, and an external device. As compared with the QADC, the eQADC system requires two pieces of extra hardware.

1. An eDMA or an MCU is required to move data between the eQADC's FIFOs and queues in the system memory.
2. A serial interface [eQADC synchronous serial interface (SSI)] is implemented to transmit and receive data between the eQADC and the external device.

Because there are only FIFOs inside the eQADC, much of the terminology or use of the register names, register contents, and signals of the eQADC involve FIFO instead of queue. These register names, register contents, and signals are functionally equivalent to the queue counterparts in the QADC. Table 18-59 lists how the eQADC register, register contents, and signals are related to QADC.

Table 18-59. Terminology Comparison between QADC and eQADC

QADC Terminology	eQADC Terminology	Function
CCW	Command Message	In the QADC, the hardware only executes conversion command words. In the eQADC, not all commands are conversion commands; some are configuration commands.
Queue Trigger	CFIFO Trigger	In the QADC, a trigger event is required to start the execution of a queue. In the eQADC, a trigger event is required to start command transfers from a CFIFO. When a CFIFO is triggered and transferring, commands are continuously moved from command queues to CFIFOs. Thus, the trigger event initiates the “execution of a queue” indirectly.
Command Word Pointer Queue <i>n</i> (CWPQ n)	Counter Value of Commands Transferred from Command FIFOn (TC_CF n)	In the QADC, CWPQ n allows the last executed command on queue <i>n</i> to be determined. In the eQADC, the TC_CF n value allows the last transferred command on command queue <i>n</i> to be determined.
Queue Pause Bit (P)	CFIFO Pause Bit	In the QADC, detecting a pause bit in the CCW pauses the queue execution. In the eQADC, detecting a pause bit in the command pauses command transfers from a CFIFO.
Queue Operation Mode (MQ n)	CFIFO Operation Mode (MODE n)	The eQADC supports all queue operation modes in the QADC except operation modes related to a periodic timer. A timer elsewhere in the system can provide the same functionality if it is connected to ETRIG n .
Queue Status (QS)	CFIFO Status (CFS n)	In the QADC, the queue status is read to check whether a queue is idle, active, paused, suspended, or trigger pending. In the eQADC, the CFIFO status is read to check whether a queue is IDLE, WAITING FOR TRIGGER (idle or paused in QADC), or triggered (suspended or trigger pending in QADC).

The eQADC and QADC also have similar procedures for the configuration or execution of applications. [Table 18-60](#) shows the steps required for the QADC versus the steps required for the eQADC system.

Table 18-60. Usage Comparison between QADC and eQADC System

Procedure	QADC	eQADC System
Analog Control Configuration	Configure analog device by writing to the QADCs.	Program configuration commands into command queues.
Prepare Scan Sequence	Program scan commands into command queues.	Program scan commands into command queues.
Queue Control Configuration	Write to the QADC control registers.	Write to the eQADC control registers.
Data Transferred between Queues and Buffers	Not Required.	Program the eDMA or the CPU to handle the data transfer.
Serial Interface Configuration	Not Required.	Write to the eQADC SSI registers.
Queue Execution	Require software or external trigger events to start queue execution.	Require software or external trigger events to start command transfers from a CFIFO.

18.6 Document Revision History

Table 18-61. Changes Between MPC5565RM Revisions 0.1 and 1

Removed section 9.2 “Detailed Signals” from this chapter because this information is contained in the Signals chapter of the Reference Manual.
Added this cross reference to the EQADC_NMSFR[NMF] bit: “Refer to the section “Null Message Format for External Device Operation” for more information.”

Chapter 19

Deserial Serial Peripheral Interface (DSPI)

19.1 Introduction

This chapter describes the deserial serial peripheral interface (DSPI), which provides a synchronous serial bus for communication between the MCU and an external peripheral device.

Microcontroller chips in the MPC55xx family implement different DSPI modules. Some implement DSPI A, B, C, and D, and others implement only B, C, and D, for example. The “x” appended to signal names signifies the module to which the signal applies. Thus PCS_x[0] specifies that the PCS signal applies to module A, B, etc.

19.1.1 Block Diagram

A block diagram of the DSPI is shown in [Figure 19-1](#).

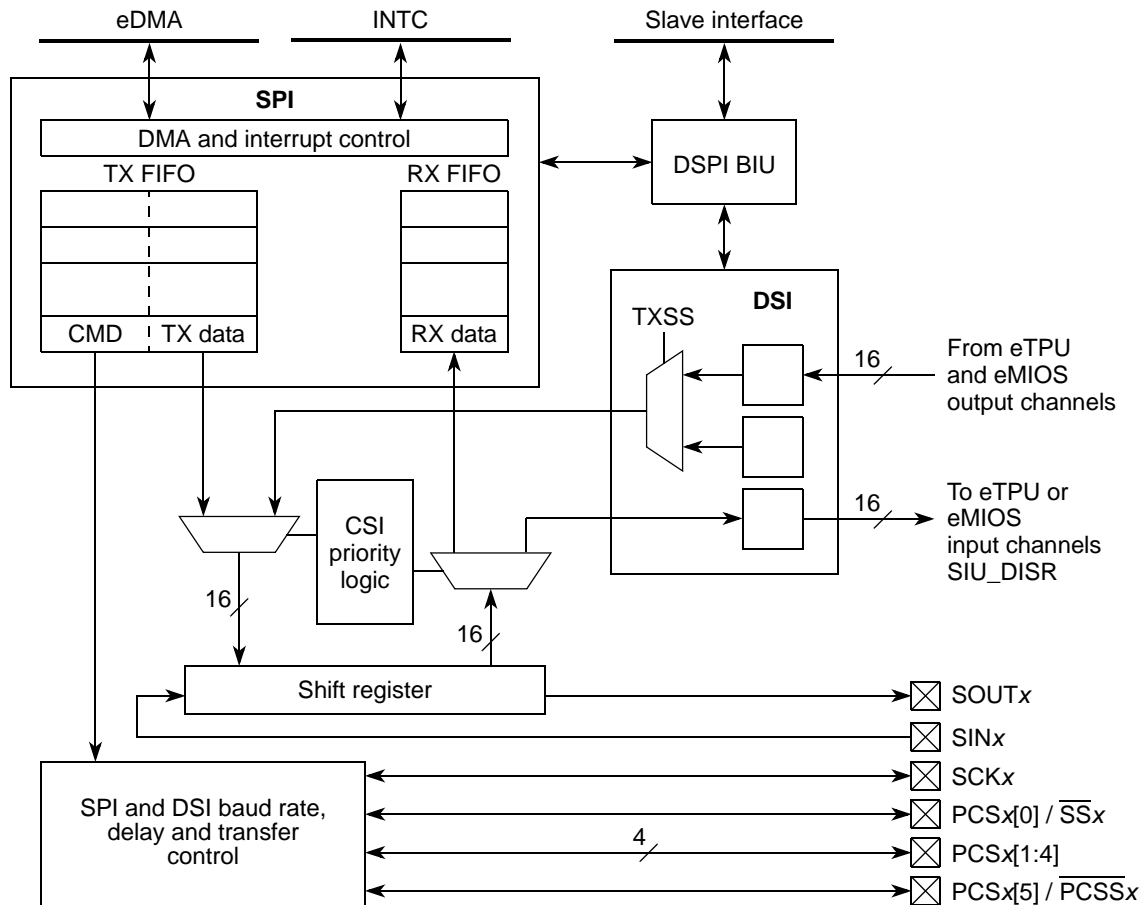

Figure 19-1. DSPI Block Diagram

19.1.2 Overview

The DSPI supports pin count reduction through serialization and deserialization of eTPU channels, eMIOS channels, and memory-mapped registers. Incoming serial data may be used to trigger external interrupt requests through DSPI deserialized output connections to the SIU. The channels and register content are transmitted using an SPI protocol. There are three identical DSPI modules (DSPI B, DSPI C, and DSPI D) on the device.

The DSPI has three configurations:

- Serial peripheral interface (SPI) configuration where the DSPI operates as an SPI with support for queues.
- Deserial serial interface (DSI) configuration where the DSPI serializes eTPU and eMIOS output channels and deserializes the received data by placing the data on the eTPU and eMIOS input channels and as inputs to the external interrupt request submodule of the SIU.
- Combined serial interface (CSI) configuration where the DSPI operates in both SPI and DSI configurations interleaving DSI frames with SPI frames, giving priority to SPI frames.

For queued operations the SPI queues reside in internal SRAM which is external to the DSPI. Data transfers between the queues and the DSPI FIFOs are accomplished through the use of the eDMA controller or through host software.

Figure 19-2 shows a DSPI with external queues in internal SRAM.

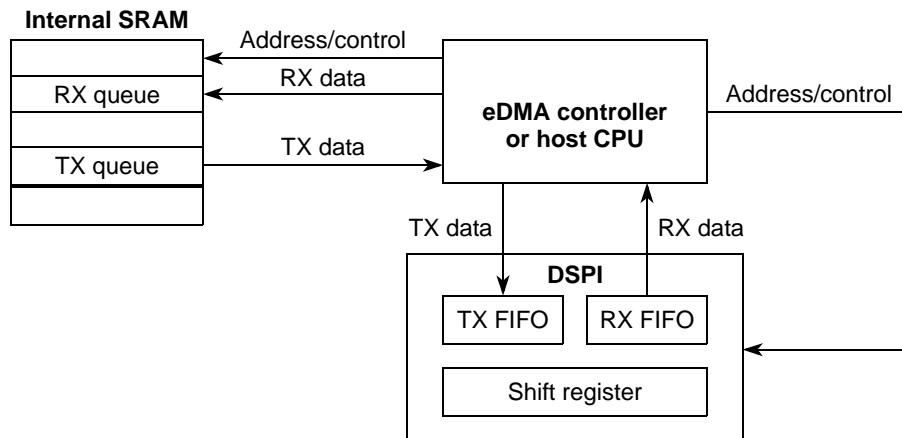

Figure 19-2. DSPI with Queues and eDMA

19.1.3 Features

The DSPI supports these SPI features:

- Full-duplex, three-wire synchronous transfers
- Master and slave mode
- Buffered transmit and receive operation using the TX and RX FIFOs, with depths of four entries
- Visibility into TX and RX FIFOs for ease of debugging
- FIFO bypass mode for low-latency updates to SPI queues

Deserial Serial Peripheral Interface (DSPI)

- Programmable transfer attributes on a per-frame basis
 - Eight clock and transfer attribute registers
 - Serial clock with programmable polarity and phase
 - Programmable delays
 - PCS to SCK delay
 - SCK to PCS delay
 - Delay between frames
 - Programmable serial frame size of 4 to 16 bits, expandable with software control
 - Continuously held chip select capability
- Six peripheral chip selects, expandable to 64 with external demultiplexer
- Deglitching support for up to 32 peripheral chip selects with external demultiplexer
- Two DMA conditions for SPI queues residing in RAM or flash
 - TX FIFO is not full (TFFF)
 - RX FIFO is not empty (RFDF)
- Six interrupt conditions:
 - End of queue reached (EOQF)
 - TX FIFO is not full (TFFF)
 - Transfer of current frame complete (TCF)
 - RX FIFO is not empty (RFDF)
 - FIFO overrun (attempt to transmit with an empty TX FIFO or serial frame received while RX FIFO is full) (RFOF)
 - FIFO under flow (slave only and SPI mode, the slave is asked to transfer data when the TX FIFO is empty) (TFUF)
- Modified SPI transfer formats for communication with slower peripheral devices
- Supports all functional modes from QSPI subblock of QSMCM (MPC500 family)
- Continuous serial communications clock (SCK)

When configured for DSI or CSI operation, the DSPI supports pin reduction through serialization and deserialization.

- Serialized data sources
 - eTPUA, and eMIOS output channels
 - Memory-mapped register in the DSPI
- Deserialized data destinations
 - eTPUA and eMIOS input channels
 - SIU external interrupt request inputs
 - Memory-mapped register in the DSPI

- Transfer initiation conditions
 - Continuous
 - Edge-sensitive hardware trigger
 - Change in data
- Support for parallel and serial chaining of DSPI modules
- Pin serialization/deserialization with interleaved SPI frames for control and diagnostics

19.1.4 Modes of Operation

The DSPI has four modes of operation. These modes can be divided into two categories; module-specific modes such as master, slave, and module disable modes, and a second category that is an MCU-specific mode: debug mode.

The module-specific modes are entered by host software writing to a register. The MCU-specific mode is controlled by signals external to the DSPI. The MCU-specific mode is a mode that the entire device may enter, in parallel to the DSPI being in one of its module-specific modes.

19.1.4.1 Master Mode

Master mode allows the DSPI to initiate and control serial communication. In this mode the SCK, PCS n and SOUT signals are controlled by the DSPI and configured as outputs.

For more information, refer to [Section 19.4.1.1, “Master Mode.”](#)

19.1.4.2 Slave Mode

Slave mode allows the DSPI to communicate with SPI / DSI bus masters. In this mode the DSPI responds to externally controlled serial transfers. The DSPI cannot initiate serial transfers in slave mode. In slave mode, the SCK signal and the PCS x [0] / \overline{SS} signal are configured as inputs and provided by a bus master. PCS x [0] / \overline{SS} must be configured as input and pulled high. If the internal pullup is being used then the appropriate bits in the relevant SIU_PCR must be set (SIU_PCR [WPE = 1], [WPS = 1]).

For more information, refer to [Section 19.4.1.2, “Slave Mode.”](#)

19.1.4.3 Module Disable Mode

The module disable mode is used for MCU power management. The clock to the non-memory mapped logic in the DSPI is stopped while in module disable mode. The DSPI enters the module disable mode when the MDIS bit in DSPI x _MCR is set.

For more information, refer to [Section 19.4.1.3, “Module Disable Mode.”](#)

19.1.4.4 Debug Mode

Debug mode is used for system development and debugging. If the device enters debug mode while the FRZ bit in the DSPIx_MCR is set, the DSPI halts operation on the next frame boundary. If the device enters debug mode while the FRZ bit is cleared, the DSPI behavior is unaffected and remains dictated by the module-specific mode and configuration of the DSPI.

For more information, refer to [Section 19.4.1.4, “Debug Mode.”](#)

19.2 External Signal Description

19.2.1 Signal Overview

Table 19-1 lists off-chip DSPI signals.

Table 19-1. Signal Properties

Name	I/O Type	Function	
		Master Mode	Slave Mode
PCSx[0] / \overline{SS}	Output / input	Peripheral chip select 0	Slave select
PCSx[1:3]	Output	Peripheral chip select 1–3	Unused ¹
PCSx[4] / \overline{MTRIG}	Output	Peripheral chip select 4	Master trigger
PCSx[5] / \overline{PCSS}	Output	Peripheral chip select 5 / Peripheral chip select strobe	Unused ¹
SINx	Input	Serial data in	Serial data in
SOUTx	Output	Serial data out	Serial data out
SCKx	Output / input	Serial clock (output)	Serial clock (input)

¹ The SIU allows you to select alternate pin functions for the device.

19.2.2 Signal Names and Descriptions

19.2.2.1 Peripheral Chip Select / Slave Select (PCSx[0] / \overline{SS})

In master mode, the PCSx[0] signal is a peripheral chip select output that selects the slave device to which the current transmission is intended.

In slave mode, the \overline{SS} signal is a slave select input signal that allows an SPI master to select the DSPI as the target for transmission. PCSx[0] / \overline{SS} must be configured as input and pulled high. If the internal pullup is being used then the appropriate bits in the relevant SIU_PCR must be set (SIU_PCR [WPE = 1], [WPS = 1]).

Set the IBE and OBE bits in the SIU_PCR for all PCSx[0] pins when the DSPI chip select or slave select primary function is selected for that pin. When the pin is used for DSPI master mode as a chip select output, set the OBE bit. When the pin is used in DSPI slave mode as a slave select input, set the IBE bit.

Refer to [Section 6.3.1.12, “Pad Configuration Registers \(SIU_PCR\),”](#) for more information.

19.2.2.2 Peripheral Chip Selects 1–3 (PCSx[1:3])

PCSx[1:3] are peripheral chip select output signals in master mode. In slave mode these signals are not used.

19.2.2.3 Peripheral Chip Select 4/Master Trigger (PCSx[4]/ $\overline{\text{MTRIG}}$)

PCSx[4] is a peripheral chip select output signal in master mode. In slave mode this signal is a master trigger.

19.2.2.4 Peripheral Chip Select 5/Peripheral Chip Select Strobe (PCSx[5]/PCSS)

PCSx[5] is a peripheral chip select output signal. When the DSPI is in master mode and PCSSE bit in the DSPIx_MCR is cleared, the PCSx[5] signal is used to select the slave device that receives the current transfer.

$\overline{\text{PCSS}}$ is a strobe signal used by external logic for deglitching of the PCS signals. When the DSPI is in master mode and the PCSSE bit in the DSPIx_MCR is set, the $\overline{\text{PCSS}}$ signal indicates the timing to decode PCSx[0:4] signals, which prevents glitches from occurring.

PCSx[5]/ $\overline{\text{PCSS}}$ is not used in slave mode.

19.2.2.5 Serial Input (SINx)

SINx is a serial data input signal.

19.2.2.6 Serial Output (SOUTx)

SOUTx is a serial data output signal.

19.2.2.7 Serial Clock (SCKx)

SCKx is a serial communication clock signal. In master mode, the DSPI generates the SCK. In slave mode, SCKx is an input from an external bus master.

19.3 Memory Map and Register Definition

19.3.1 Memory Map

Table 19-2 shows the DSPI memory map.

Table 19-2. DSPI Detailed Memory Map

Address	Register Name	Register Description	Bits
Base: 0xFFFF9_4000 (DSPI B) 0xFFFF9_8000 (DSPI C) 0xFFFF9_C000 (DSPI D)	DSPIx_MCR	DSPI module configuration register	32

19.3.2 Register Descriptions

19.3.2.1 DSPI Module Configuration Register (DSPIx_MCR)

The DSPIx_MCR contains bits which configure attributes of the DSPI operation. The values of the HALT and MDIS bits can be changed at any time, but their effect begins on the next frame boundary. The HALT and MDIS bits in the DSPIx_MCR are the only bit values software can change while the DSPI is running.

Figure 19-3. DSPI Module Configuration Register (DSPIx_MCR)

The following table describes the fields in the DSPI module configuration register:

Table 19-3. DSPIx_MCR Field Descriptions

Field	Description
0 MSTR	Master/slave mode select. Configures the DSPI for master mode or slave mode. 0 DSPI is in slave mode 1 DSPI is in master mode
1 CONT_SCKE	Continuous SCK enable. Enables the serial communication clock (SCK) to run continuously. Refer to Section 19.4.8, "Continuous Serial Communications Clock," for details. 0 Continuous SCK disabled 1 Continuous SCK enabled

Table 19-3. DSPIx_MCR Field Descriptions (continued)

Field	Description										
2–3 DCONF [0:1]	<p>DSPI configuration. Selects between the three different configurations of the DSPI. The following table lists the DCONF values for the various configurations.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>DCONF</th> <th>Configuration</th> </tr> </thead> <tbody> <tr> <td>00</td> <td>SPI</td> </tr> <tr> <td>01</td> <td>DSI</td> </tr> <tr> <td>10</td> <td>CSI</td> </tr> <tr> <td>11</td> <td>Invalid value</td> </tr> </tbody> </table>	DCONF	Configuration	00	SPI	01	DSI	10	CSI	11	Invalid value
DCONF	Configuration										
00	SPI										
01	DSI										
10	CSI										
11	Invalid value										
4 FRZ	<p>Freeze. Enables the DSPI transfers to be stopped on the next frame boundary when the device enters debug mode.</p> <p>0 Do not halt serial transfers 1 Halt serial transfers</p>										
5 MTFE	<p>Modified timing format enable. Enables a modified transfer format to be used. Refer to Section 19.4.7.4, “Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)”, for more information.</p> <p>0 Modified SPI transfer format disabled 1 Modified SPI transfer format enabled</p>										
6 PCSSE	<p>Peripheral chip select strobe enable. Enables the PCSx[5] / $\overline{\text{PCSS}}$ to operate as a PCS strobe output signal. Refer to Section 19.4.6.5, “Peripheral Chip Select Strobe Enable (PCSSE)”, for more information.</p> <p>0 PCSx[5] / $\overline{\text{PCSS}}$ is used as the Peripheral chip select 5 signal 1 PCSx[5] / $\overline{\text{PCSS}}$ is used as an active-low PCS strobe signal</p>										
7 ROOE	<p>Receive FIFO overflow overwrite enable. Enables an RX FIFO overflow condition to ignore the incoming serial data or to overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer that generated the overflow is ignored or put in the shift register.</p> <p>If the ROOE bit is set, the incoming data is put in the shift register. If the ROOE bit is cleared, the incoming data is ignored. Refer to Section 19.4.9.6, “Receive FIFO Overflow Interrupt Request (RFOF)”, for more information.</p> <p>0 Incoming data is ignored 1 Incoming data is put in the shift register</p>										
8–9	Reserved, but implemented. These bits are writable, but have no effect.										
10–15 PCSiSn	<p>Peripheral chip select inactive state. Determines the inactive state of the PCSxn signal. PCSx[0] / $\overline{\text{SS}}$ must be configured as inactive high for slave mode operation.</p> <p>0 The inactive state of PCSxn is low 1 The inactive state of PCSxn is high</p>										
16	Reserved.										

Table 19-3. DSPIx_MCR Field Descriptions (continued)

Field	Description										
17 MDIS	<p>Module disable. Allows the clock to stop to the non-memory mapped logic in the DSPI, effectively putting the DSPI in a software controlled power-saving state. Refer to Section 19.4.10, “Power Saving Features for more information.” The reset value of the MDIS bit is parameterized, with a default reset value of 0.</p> <p>0 Enable DSPI clocks 1 Allow external logic to disable DSPI clocks</p>										
18 DIS_TXF	<p>Disable transmit FIFO. Enables and disables the TX FIFO. When the TX FIFO is disabled, the transmit part of the DSPI operates as a simplified double-buffered SPI. Refer to Section 19.4.3.3, “FIFO Disable Operation for details.”</p> <p>0 TX FIFO is enabled 1 TX FIFO is disabled</p>										
19 DIS_RXF	<p>Disable receive FIFO. Enables and disables the RX FIFO. When the RX FIFO is disabled, the receive part of the DSPI operates as a simplified double-buffered SPI. Refer to Section 19.4.3.3, “FIFO Disable Operation for details.”</p> <p>0 RX FIFO is enabled 1 RX FIFO is disabled</p>										
20 CLR_TXF	<p>Clear TX FIFO. Flushes the TX FIFO. Write a 1 to the CLR_TXF bit to clear the TX FIFO counter. The CLR_TXF bit is always read as zero.</p> <p>0 Do not clear the TX FIFO counter 1 Clear the TX FIFO counter</p>										
21 CLR_RXF	<p>Clear RX FIFO. Flushes the RX FIFO. Write a 1 to the CLR_RXF bit to clear the RX counter. The CLR_RXF bit is always read as zero.</p> <p>0 Do not clear the RX FIFO counter 1 Clear the RX FIFO counter</p>										
22–23 SMPL_PT [0:1]	<p>Sample point. Allows the host software to select when the DSPI master samples SIN in modified transfer format. Figure 19-34 shows where the master can sample the SIN pin. The following table lists the delayed sample points.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>SMPL_PT</th> <th>Number of system clock cycles between odd-numbered edge of SCKx and sampling of SINx.</th> </tr> </thead> <tbody> <tr> <td>00</td> <td>0</td> </tr> <tr> <td>01</td> <td>1</td> </tr> <tr> <td>10</td> <td>2</td> </tr> <tr> <td>11</td> <td>Invalid value</td> </tr> </tbody> </table>	SMPL_PT	Number of system clock cycles between odd-numbered edge of SCKx and sampling of SINx.	00	0	01	1	10	2	11	Invalid value
SMPL_PT	Number of system clock cycles between odd-numbered edge of SCKx and sampling of SINx.										
00	0										
01	1										
10	2										
11	Invalid value										
24–30	Reserved.										
31 HALT	<p>Halt. Provides a mechanism for software to start and stop DSPI transfers. Refer to Section 19.4.2, “Start and Stop of DSPI Transfers,” for details on the operation of this bit.</p> <p>0 Start transfers 1 Stop transfers</p>										

19.3.2.2 DSPI Transfer Count Register (DSPIx_TCR)

The DSPIx_TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. The user must not write to the DSPIx_TCR while the DSPI is running.

Address: Base + 0x0008

Access: R/W

Figure 19-4. DSPI Transfer Count Register (DSPIx_TCR)

The following table describes the field in the DSPI transfer count register:

Table 19-4. DSPIx_TCR Field Descriptions

Field	Description
0–15 SPI_TCNT [0:15]	SPI transfer counter. Counts the number of SPI transfers the DSPI makes. The SPI_TCNT field is incremented every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The transfer counter ‘wraps around,’ incrementing the counter past 65535 resets the counter to zero.
16–31	Reserved.

19.3.2.3 DSPI Clock and Transfer Attributes Registers 0–7 (DSPIx_CTARn)

The DSPI modules each contain eight clock and transfer attribute registers (DSPIx_CTARn) which are used to define different transfer attribute configurations. Each DSPIx_CTAR controls:

- Frame size
- Baud rate and transfer delay values
- Clock phase
- Clock polarity
- MSB or LSB first

DSPIx_CTARs support compatibility with the QSPI module in the MPC5xx family of MCUs. Refer to [Section 19.5.4, “MPC5xx QSPI Compatibility with the DSPI,”](#) for a discussion on DSPI/QSPI compatibility. At the initiation of an SPI or DSI transfer, control logic selects the DSPIx_CTAR that contains the transfer’s attributes. Do not write to the DSPIx_CTARs while the DSPI is running.

In master mode, the DSPIx_CTARn registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bit fields in the DSPIx_CTAR0 and DSPIx_CTAR1 registers are used to set the slave transfer attributes. Refer to the individual bit descriptions for details on which bits are used in slave modes.

When the DSPI is configured as an SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the DSPIx_CTAR registers is used on a per-frame basis. When the DSPI is configured as an SPI bus slave, the DSPIx_CTAR0 register is used.

When the DSPI is configured as a DSI master, the DSICTAS field in the DSPI DSI configuration register (DSPIx_DSICR) selects which of the DSPIx_CTAR register is used. For more information on the DSPIx_DSICR, refer to [Section 19.3.2.10, “DSPI DSI Configuration Register \(DSPIx_DSICR\).”](#) When the DSPI is configured as a DSI bus slave, the DSPIx_CTAR1 register is used.

In CSI configuration, the transfer attributes are selected based on whether the current frame is SPI data or DSI data. SPI transfers in CSI configuration follow the protocol described for SPI configuration, and DSI transfers in CSI configuration follow the protocol described for DSI configuration. CSI configuration is only valid in conjunction with master mode. Refer to [Section 19.4.5, “Combined Serial Interface \(CSI\) Configuration”](#) for more details.

Figure 19-5. DSPI Clock and Transfer Attributes Registers 0–7 (DSPIx_CTARn)

The following table describes the fields in the DSPI clock and transfer attributes register:

Table 19-5. DSPIx_CTARn Field Description

Field	Description																																								
0 DBR	<p>Double baud rate. The DBR bit doubles the effective baud rate of the serial communications clock (SCK). This field is only used in master mode. It effectively halves the baud rate division ratio supporting faster frequencies and odd division ratios for the serial communications clock (SCK). When the DBR bit is set, the duty cycle of the serial communications clock (SCK) depends on the value in the baud rate prescaler and the clock phase bit as listed in the following table. Refer to the BR field below and Section 19.4.6.1, “Baud Rate Generator” for details on how to compute the baud rate. If the overall baud rate is divided by two or divided by three of the system clock, do not enable continuous SCK or the modified timing format.</p> <p>0 The baud rate is computed normally with a 50/50 duty cycle 1 Baud rate is doubled with the duty cycle depending on the baud rate prescaler</p> <table border="1"> <thead> <tr> <th>DBR</th> <th>CPHA</th> <th>PBR</th> <th>SCK Duty Cycle</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>any</td> <td>any</td> <td>50/50</td> </tr> <tr> <td>1</td> <td>0</td> <td>00</td> <td>50/50</td> </tr> <tr> <td>1</td> <td>0</td> <td>01</td> <td>33/66</td> </tr> <tr> <td>1</td> <td>0</td> <td>10</td> <td>40/60</td> </tr> <tr> <td>1</td> <td>0</td> <td>11</td> <td>43/57</td> </tr> <tr> <td>1</td> <td>1</td> <td>00</td> <td>50/50</td> </tr> <tr> <td>1</td> <td>1</td> <td>01</td> <td>66/33</td> </tr> <tr> <td>1</td> <td>1</td> <td>10</td> <td>60/40</td> </tr> <tr> <td>1</td> <td>1</td> <td>11</td> <td>57/43</td> </tr> </tbody> </table>	DBR	CPHA	PBR	SCK Duty Cycle	0	any	any	50/50	1	0	00	50/50	1	0	01	33/66	1	0	10	40/60	1	0	11	43/57	1	1	00	50/50	1	1	01	66/33	1	1	10	60/40	1	1	11	57/43

Table 19-5. DSPI_x_CTAR_n Field Description (continued)

Field	Description										
5 CPOL	<p>Clock polarity. Selects the inactive state of the serial communications clock (SCK_x). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the continuous selection format is selected (CONT = 1 or DCONT = 1), switching between clock polarities without stopping the DSPI can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. For more information on continuous selection format, refer to Section 19.4.7.5, “Continuous Selection Format.”</p> <p>0 The inactive state value of SCK_x is low 1 The inactive state value of SCK_x is high</p>										
6 CPHA	<p>Clock phase. Selects which edge of SCK_x causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings.</p> <p>0 Data is captured on the leading edge of SCK_x and changed on the following edge 1 Data is changed on the leading edge of SCK_x and captured on the following edge</p>										
7 LSBFE	<p>LSB first enable. Selects if the LSB or MSB of the frame is transferred first. This bit is only used in master mode.</p> <p>0 Data is transferred MSB first 1 Data is transferred LSB first</p>										
8–9 PCSSCK [0:1]	<p>PCS_x to SCK_x delay prescaler. Selects the prescaler value for the delay between assertion of PCS_x and the first edge of the SCK_x. Use in master mode only. The following table lists the prescaler values. The description for bitfield CSSCK in Table 19-5 details how to compute the PCS to SCK delay.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>PCSSCK</th> <th>PCS_x to SCK_x Delay Prescaler Value</th> </tr> </thead> <tbody> <tr> <td>00</td> <td>1</td> </tr> <tr> <td>01</td> <td>3</td> </tr> <tr> <td>10</td> <td>5</td> </tr> <tr> <td>11</td> <td>7</td> </tr> </tbody> </table>	PCSSCK	PCS _x to SCK _x Delay Prescaler Value	00	1	01	3	10	5	11	7

19.3.2.4 DSPI Status Register (DSPIx_SR)

The DSPIx_SR contains status and flag bits. The bits are set by the hardware and reflect the status of the DSPI and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the DSPIx_SR by writing a 1 to clear it (w1c). Writing a 0 to a flag bit has no effect.

Figure 19-6. DSPI Status Register (DSPIx_SR)

The following table describes the fields in the DSPI status register:

Table 19-6. DSPIx_SR Field Descriptions

Field	Description
0 TCF	Transfer complete flag. Indicates that all bits in a frame have been shifted out. The TCF bit is set after the last incoming databit is sampled, but before the tASC delay starts. Refer to Section 19.4.7.1, “Classic SPI Transfer Format (CPHA = 0)” for details. The TCF bit is cleared by writing 1 to it. 0 Transfer not complete 1 Transfer complete
1 TXRXS	TX and RX status. Reflects the status of the DSPI. Refer to Section 19.4.2, “Start and Stop of DSPI Transfers” for information on what clears and sets this bit. 0 TX and RX operations are disabled (DSPI is in STOPPED state) 1 TX and RX operations are enabled (DSPI is in RUNNING state)
2	Reserved.
3 EOQF	End of queue flag. Indicates that transmission in progress is the last entry in a queue. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and after the last incoming databit is sampled, but before the tASC delay starts. Refer to Section 19.4.7.1, “Classic SPI Transfer Format (CPHA = 0)” for details. The EOQF bit is cleared by writing 1 to it. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command 1 EOQ bit is set in the executing SPI command Note: EOQF does not function in slave mode.
4 TFUF	Transmit FIFO underflow flag. Indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for DSPI modules operating in slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of a DSPI operating in SPI slave mode is empty, and a transfer is initiated by an external SPI master. The TFUF bit is cleared by writing 1 to it. 0 TX FIFO underflow has not occurred 1 TX FIFO underflow has occurred
5	Reserved.
6 TFFF	Transmit FIFO fill flag. Indicates that the TX FIFO can be filled. Provides a method for the DSPI to request more entries to be added to the TX FIFO. The TFFF bit is set while the TX FIFO is not full. The TFFF bit can be cleared by writing 1 to it, or an by acknowledgement from the eDMA controller when the TX FIFO is full. 0 TX FIFO is full 1 TX FIFO is not full
7–11	Reserved.
12 RFOF	Receive FIFO overflow flag. Indicates that an overflow condition in the RX FIFO has occurred. The bit is set when the RX FIFO and shift register are full and a transfer is initiated. The bit is cleared by writing 1 to it. 0 RX FIFO overflow has not occurred 1 RX FIFO overflow has occurred
13	Reserved.

Table 19-6. DSPIx_SR Field Descriptions (continued)

Field	Description
14 RFDF	Receive FIFO drain flag. Indicates that the RX FIFO can be drained. Provides a method for the DSPI to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it, or by acknowledgement from the eDMA controller when the RX FIFO is empty. 0 RX FIFO is empty 1 RX FIFO is not empty Note: In the interrupt service routine, RFDF must be cleared only after the DSPIx_POPR register is read.
15	Reserved.
16–19 TXCTR [0:3]	TX FIFO counter. Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the DSPI_PUSH is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
20–23 TXNXTPTR [0:3]	Transmit next pointer. Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register. Refer to Section 19.4.3.4, “Transmit First In First Out (TX FIFO) Buffering Mechanism” for more details.
24–27 RXCTR [0:3]	RX FIFO counter. Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the DSPI_POPR is read. The RXCTR is incremented after the last incoming databit is sampled, but before the tASC delay starts. Refer to Section 19.4.7.1, “Classic SPI Transfer Format (CPHA = 0)” for details.
28–31 POPNTPTR [0:3]	Pop next pointer. Contains a pointer to the RX FIFO entry that is returned when the DSPI_POPR is read. The POPNTPTR is updated when the DSPI_POPR is read. Refer to Section 19.4.3.5, “Receive First In First Out (RX FIFO) Buffering Mechanism” for more details.

19.3.2.5 DSPI DMA / Interrupt Request Select and Enable Register (DSPIx_RSER)

The DSPIx_RSER serves two purposes: enables flag bits in the DSPIx_SR to generate DMA requests or interrupt requests, and selects the type of request to generate. Refer to the bit descriptions for the type of requests that are supported. Do not write to the DSPIx_RSER while the DSPI is running.

Figure 19-7. DSPI DMA / Interrupt Request Select and Enable Register (DSPIx_RSER)

The following table describes the fields in the DSPI DMA / interrupt request and enable register:

Table 19-7. DSPIx_RSER Field Descriptions

Field	Description
0 TCF_RE	Transmission complete request enable. Enables TCF flag in the DSPIx_SR to generate an interrupt request. 0 TCF interrupt requests are disabled 1 TCF interrupt requests are enabled
1–2	Reserved.
3 EOQF_RE	DSPI finished request enable. Enables the EOQF flag in the DSPIx_SR to generate an interrupt request. 0 EOQF interrupt requests are disabled 1 EOQF interrupt requests are enabled
4 TFUF_RE	Transmit FIFO underflow request enable. The TFUF_RE bit enables the TFUF flag in the DSPIx_SR to generate an interrupt request. 0 TFUF interrupt requests are disabled 1 TFUF interrupt requests are enabled
5	Reserved.
6 TFFF_RE	Transmit FIFO fill request enable. Enables the TFFF flag in the DSPIx_SR to generate a request. The TFFF_DIRS bit selects between generating an interrupt request or a DMA requests. 0 TFFF interrupt requests or DMA requests are disabled 1 TFFF interrupt requests or DMA requests are enabled
7 TFFF_DIRS	Transmit FIFO fill DMA or interrupt request select. Selects between generating a DMA request or an interrupt request. When the TFFF flag bit in the DSPIx_SR is set, and the TFFF_RE bit in the DSPIx_RSER is set, this bit selects between generating an interrupt request or a DMA request. 0 Interrupt request is selected 1 DMA request is selected
8–11	Reserved.
12 RFOF_RE	Receive FIFO overflow request enable. Enables the RFOF flag in the DSPIx_SR to generate an interrupt requests. 0 RFOF interrupt requests are disabled 1 RFOF interrupt requests are enabled
13	Reserved.
14 RFDF_RE	Receive FIFO drain request enable. Enables the RFDF flag in the DSPIx_SR to generate a request. The RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 RFDF interrupt requests or DMA requests are disabled 1 RFDF interrupt requests or DMA requests are enabled

Table 19-7. DSPIx_RSER Field Descriptions (continued)

Field	Description
15 RFDF_DIRS	Receive FIFO drain DMA or interrupt request select. Selects between generating a DMA request or an interrupt request. When the RFDF flag bit in the DSPIx_SR is set, and the RFDF_RE bit in the DSPIx_RSER is set, the RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request is selected 1 DMA request is selected
16–31	Reserved.

19.3.2.6 DSPI PUSH TX FIFO Register (DSPIx_PUSHR)

The DSPIx_PUSHR provides a means to write to the TX FIFO. Data written to this register is transferred to the TX FIFO. Refer to [Section 19.4.3.4, “Transmit First In First Out \(TX FIFO\) Buffering Mechanism,”](#) for more information. Write accesses of 8- or 16-bits to the DSPIx_PUSHR transfers 32 bits to the TX FIFO.

NOTE

TXDATA is used in master and slave modes.

Address: Base + 0x0034

Access: R/W

Figure 19-8. DSPI PUSH TX FIFO Register (DSPIx_PUSHR)

The following table describes the fields in the DSPI push transmit FIFO register:

Table 19-8. DSPIx_PUSHR Field Descriptions

Field	Description																		
0 CONT	<p>Continuous peripheral chip select enable. Selects a continuous selection format. The bit is used in SPI master mode. The bit enables the selected PCS signals to remain asserted between transfers. Refer to Section 19.4.7.5, “Continuous Selection Format,” for more information.</p> <p>0 Return peripheral chip select signals to their inactive state between transfers 1 Keep peripheral chip select signals asserted between transfers</p>																		
1–3 CTAS [0:2]	<p>Clock and transfer attributes select. Selects which of the DSPIx_CTARs is used to set the transfer attributes for the SPI frame. In SPI slave mode, DSPIx_CTAR0 is used. The following table shows how the CTAS values map to the DSPIx_CTARs. There are eight DSPIx_CTARs in the device DSPI implementation.</p> <p>Note: Use in SPI master mode only.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>CTAS</th> <th>Use Clock and Transfer Attributes from</th> </tr> </thead> <tbody> <tr> <td>000</td> <td>DSPIx_CTAR0</td> </tr> <tr> <td>001</td> <td>DSPIx_CTAR1</td> </tr> <tr> <td>010</td> <td>DSPIx_CTAR2</td> </tr> <tr> <td>011</td> <td>DSPIx_CTAR3</td> </tr> <tr> <td>100</td> <td>DSPIx_CTAR4</td> </tr> <tr> <td>101</td> <td>DSPIx_CTAR5</td> </tr> <tr> <td>110</td> <td>DSPIx_CTAR6</td> </tr> <tr> <td>111</td> <td>DSPIx_CTAR7</td> </tr> </tbody> </table>	CTAS	Use Clock and Transfer Attributes from	000	DSPIx_CTAR0	001	DSPIx_CTAR1	010	DSPIx_CTAR2	011	DSPIx_CTAR3	100	DSPIx_CTAR4	101	DSPIx_CTAR5	110	DSPIx_CTAR6	111	DSPIx_CTAR7
CTAS	Use Clock and Transfer Attributes from																		
000	DSPIx_CTAR0																		
001	DSPIx_CTAR1

011	DSPIx_CTAR3																		
100	DSPIx_CTAR4																		
101	DSPIx_CTAR5																		
110	DSPIx_CTAR6																		
111	DSPIx_CTAR7																		
4 EOQ	<p>End of queue. Provides a means for host software to signal to the DSPI that the current SPI transfer is the last in a queue. At the end of the transfer the EOQF bit in the DSPIx_SR is set.</p> <p>0 The SPI data is not the last data to transfer 1 The SPI data is the last data to transfer</p> <p>Note: Use in SPI master mode only.</p>																		
5 CTCNT	<p>Clear SPI_TCNT. Provides a means for host software to clear the SPI transfer counter. The CTCNT bit clears the SPI_TCNT field in the DSPIx_TCR. The SPI_TCNT field is cleared before transmission of the current SPI frame begins.</p> <p>0 Do not clear SPI_TCNT field in the DSPIx_TCR 1 Clear SPI_TCNT field in the DSPIx_TCR</p> <p>Note: Use in SPI master mode only.</p>																		
6–7	Reserved.																		
8–9	Reserved, but implemented. These bits are writable, but have no effect.																		

Table 19-8. DSPIx_PUSHR Field Descriptions (continued)

Field	Description
10–15 PCSx	Peripheral chip select x. Selects which PCSx signals are asserted for the transfer. 0 Negate the PCSx signal 1 Assert the PCSx signal Note: Use in SPI master mode only.
16–31 TXDATA [0:15]	Transmit data. Holds SPI data for transfer according to the associated SPI command. Note: Use TXDATA in master and slave modes.

19.3.2.7 DSPI POP RX FIFO Register (DSPIx_POPR)

The DSPIx_POPR allows you to read the RX FIFO. Refer to [Section 19.4.3.5, “Receive First In First Out \(RX FIFO\) Buffering Mechanism”](#) for a description of the RX FIFO operations. Eight or 16-bit read accesses to the DSPIx_POPR fetch the RX FIFO data, and update the counter and pointer.

NOTE

Reading the RX FIFO field fetches data from the RX FIFO. Once the RX FIFO is read, the read data pointer is moved to the next entry in the RX FIFO. Therefore, read DSPIx_POPR only when you need the data. For compatibility, configure the TLB (MMU table) entry for DSPIx_POPR as guarded.

Figure 19-9. DSPI POP RX FIFO Register (DSPIx_POPR)

The following table describes the fields in the DSPI pop receive FIFO register:

Table 19-9. DSPIx_POPR Field Descriptions

Field	Description
0–15	Reserved, must be cleared.
16–31 RXDATA [0:15]	Received data. The RXDATA field contains the SPI data from the RX FIFO entry pointed to by the pop next data pointer (POPNEXTPTR).

19.3.2.8 DSPI Transmit FIFO Registers 0–3 (DSPIx_TXFRn)

The DSPIx_TXFRn registers provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers are read-only and cannot be modified. Reading the DSPIx_TXFRn registers does not alter the state of the TX FIFO. The MCU uses four registers to implement the TX FIFO, that is DSPIx_TXFR0–DSPIx_TXFR3 are used.

Figure 19-12. DSPI DSI Configuration Register (DSPIx_DSICR)

The following table describes the fields in the DSPI deserial serial interface configuration register:

Table 19-12. DSPIx_DSICR Field Descriptions

Field	Description
0 MTOE	Multiple transfer operation enable. Enables multiple DSPIs connected in a parallel or serial configuration. Refer to Section 19.4.4.7, “Multiple Transfer Operation (MTO),” for more information. 0 Multiple transfer operation disabled 1 Multiple transfer operation enabled
1	Reserved.
2–7 MTOCNT [0:5]	Multiple transfer operation count. Selects number of bits to be shifted out during a transfer in multiple transfer operation. The field sets the number of SCK cycles that the bus master needs to generate to complete the transfer. The number of SCK cycles used are one more than the value in the MTOCNT field. The number of SCK cycles defined by MTOCNT must be equal to or greater than the frame size.
8–11	Reserved.
12 TXSS	Transmit data source select. Selects the source of data to be serialized. The source can be data from host software written to the DSPI DSI alternate serialization data register (DSPIx_ASDR), or parallel output pin states latched into the DSPI DSI serialization data register (DSPIx_SDR). 0 Source of serialized data is the DSPIx_SDR 1 Source of serialized data is the DSPIx_ASDR
13 TPOL	Trigger polarity. Selects the active edge of the internal hardware trigger input signal (<i>ht</i>). The bit selects which edge initiates a transfer in the DSI configuration. Refer to Section 19.4.4.5, “DSI Transfer Initiation Control,” for more information. 0 Falling-edge initiates a transfer 1 Rising-edge initiates a transfer

Table 19-12. DSPIx_DSICR Field Descriptions (continued)

Field	Description																		
14 TRRE	<p>Trigger reception enable. Enables the DSPI to initiate a transfer when an external trigger signal is received. The bit is only valid in DSI configuration. Refer to Section 19.4.4.5, “DSI Transfer Initiation Control,” for more information.</p> <p>0 Trigger signal reception disabled 1 Trigger signal reception enabled</p>																		
15 CID	<p>Change in data transfer enable. Enables a change in serialization data to initiate a transfer. The bit is used in master mode in DSI and CSI configurations to control when to initiate transfers. When the CID bit is set, serialization is initiated when the current DSI data differs from the previous DSI data shifted out. The DSPIx_COMPR is compared with the DSPIx_SDR or DSPIx_AS DR to detect a change in data. Refer to Section 19.4.4.5, “DSI Transfer Initiation Control,” for more information.</p> <p>0 Change in data transfer operation disabled 1 Change in data transfer operation enabled</p>																		
16 DCONT	<p>DSI continuous peripheral chip select enable. Enables the PCSx signals to remain asserted between transfers. The DCONT bit only affects the PCS signals in DSI master mode. Refer to Section 19.4.7.5, “Continuous Selection Format,” for details.</p> <p>0 Return peripheral chip select signals to their inactive state after transfer is complete 1 Keep peripheral chip select signals asserted after transfer is complete</p>																		
17–19 DSICTAS [0:2]	<p>DSI clock and transfer attributes select. The DSICTAS field selects which of the DSPIx_CTARs is used to provide transfer attributes in DSI configuration. The DSICTAS field is used in DSI master mode. In DSI slave mode, the DSPIx_CTAR1 is always selected. The following table lists the DSICTAS to DSPIx_CTARs mapping.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>DSICTAS</th> <th>DSI Clock and Transfer Attributes Controlled by</th> </tr> </thead> <tbody> <tr> <td>000</td> <td>DSPIx_CTAR0</td> </tr> <tr> <td>001</td> <td>DSPIx_CTAR1</td> </tr> <tr> <td>010</td> <td>DSPIx_CTAR2</td> </tr> <tr> <td>011</td> <td>DSPIx_CTAR3</td> </tr> <tr> <td>100</td> <td>DSPIx_CTAR4</td> </tr> <tr> <td>101</td> <td>DSPIx_CTAR5</td> </tr> <tr> <td>110</td> <td>DSPIx_CTAR6</td> </tr> <tr> <td>111</td> <td>DSPIx_CTAR7</td> </tr> </tbody> </table>	DSICTAS	DSI Clock and Transfer Attributes Controlled by	000	DSPIx_CTAR0	001	DSPIx_CTAR1	010	DSPIx_CTAR2	011	DSPIx_CTAR3	100	DSPIx_CTAR4	101	DSPIx_CTAR5	110	DSPIx_CTAR6	111	DSPIx_CTAR7

111	DSPIx_CTAR7																		
20–23	Reserved.																		
24–25	Reserved, but implemented. These bits are writable, but have no effect.																		
26–31 DPCSx	<p>DSI peripheral chip select <i>n</i>. The DPCS bits select which of the PCSx signals to assert during a DSI transfer. The DPCS bits assert and negate the PCSx signals in DSI master mode only.</p> <p>0 Negate PCSx 1 Assert PCSx</p>																		

19.3.2.11 DSPI DSI Serialization Data Register (DSPIx_SDR)

The DSPIx_SDR contains the signal states of the parallel input signals from the eTPU or the eMIOS. The pin states of the parallel input signals are latched into the DSPIx_SDR on the rising edge of every system clock. The DSPIx_SDR is read-only. When the TXSS bit in the DSPIx_DSICR is negated, the data in the DSPIx_SDR is the source of the serialized data.

0–15	Reserved.
16–31 SER_DATA [15:0]	Serialized data. The SER_DATA field contains the signal states of the parallel input signals. SER_DATA [15:0] maps to DSPI serialization inputs IN[15:0]. Refer to Section 19.4.4.6, “DSPI Connections to eTPUA, eMIOS and SIU.”

19.3.2.12 DSPI DSI Alternate Serialization Data Register (DSPIx_ASDR)

The DSPIx_ASDR allows the host software to write data to be serialized. When the TXSS bit in the DSPIx_DSICR is set, the data in the DSPIx_ASDR is the source of the serialized data. Writes to the DSPIx_ASDR take effect on the next frame boundary.

19.4 Functional Description

The DSPI supports full-duplex, synchronous serial communications between the MCU and peripheral devices. The DSPI can also be used to reduce the number of pins required for I/O by serializing and deserializing up to 16 parallel input/output signals from the eTPU and eMIOS. All communications are through an SPI-like protocol.

The DSPI has three configurations:

- Serial peripheral interface (SPI) configuration in which the DSPI operates as a basic SPI or a queued SPI.
- Deserial serial interface (DSI) configuration where the DSPI serializes eTPU and eMIOS output channels and deserializes the received data by placing it on the eTPU and eMIOS input channels and as inputs to the External Interrupt Request subblock of the SIU.
- Combined serial interface (CSI) configuration where the DSPI operates in both SPI and DSI configurations interleaving DSI frames with SPI frames, giving priority to SPI frames.

The DCONF field in the DSPIx_MCR register determines the DSPI configuration. Refer to [Table 19-3](#) for the DSPI configuration values.

The DSPIx_CTAR0–DSPIx_CTAR7 registers hold clock and transfer attributes. The manner in which a CTAR is selected depends on the DSPI configuration (SPI, DSI, or CSI). The SPI configuration can select which CTAR to use on a frame by frame basis by setting the CTAS field in the DSPIx_PUSHR. The DSI configuration statically selects which CTAR to use. In CSI configuration, priority logic determines if SPI data or DSI data is transferred. The type of data transferred (whether DSI or SPI) dictates which CTAR the CSI configuration uses. Refer to [Section 19.3.2.3, “DSPI Clock and Transfer Attributes Registers 0–7 \(DSPIx_CTARn\),”](#) for information on DSPIx_CTAR fields.

The 16-bit shift register in the master and the 16-bit shift register in the slave are linked by the SOUTx and SINx signals to form a distributed 32-bit register. When a data transfer operation is performed, data is serially shifted a pre-determined number of bit positions. Because the registers are linked, data is exchanged between the master and the slave; the data that was in the master’s shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the TCF bit in the DSPIx_SR is set to indicate a completed transfer. [Figure 19-17](#) illustrates how master and slave data is exchanged.

Figure 19-17. SPI and DSI Serial Protocol Overview

The DSPI has six peripheral chip select (PCSx) signals that are be used to select which of the slaves to communicate with.

Transfer protocols and timing properties are shared by the three DSPI configurations; these properties are described independently of the configuration in [Section 19.4.7, “Transfer Formats.”](#) The transfer rate and delay settings are described in [Section 19.4.6, “DSPI Baud Rate and Clock Delay Generation.”](#)

Refer to [Section 19.4.10, “Power Saving Features”](#) for information on the power-saving features of the DSPI.

19.4.1 Modes of Operation

The DSPI modules have four available distinct modes:

- Master mode
- Slave mode
- Module disable mode
- Debug mode

Master, slave, and module disable modes are module-specific modes while debug mode is a device-specific mode.

The module-specific modes are determined by bits in the DSPLx_MCR. Debug mode is a mode that the entire device can enter in parallel with the DSPI being configured in one of its module-specific modes.

19.4.1.1 Master Mode

In master mode the DSPI can initiate communications with peripheral devices. The DSPI operates as bus master when the MSTR bit in the DSPLx_MCR is set. The serial communications clock (SCK) is controlled by the master DSPI. All three DSPI configurations are valid in master mode.

In SPI configuration, master mode transfer attributes are controlled by the SPI command in the current TX FIFO entry. The CTAS field in the SPI command selects which of the eight DSPLx_CTARs are used to set the transfer attributes. Transfer attribute control is on a frame by frame basis.

Refer to [Section 19.4.3, “Serial Peripheral Interface \(SPI\) Configuration”](#) for more details.

In DSI configuration, master mode transfer attributes are controlled by the DSPLx_DSCIR. A detailed description of the DSPLx_DSCIR is located in [Section 19.3.2.10, “DSPI DSI Configuration Register \(DSPLx_DSICR\)”](#). The DSISCTAS field in the DSPLx_DSICR selects which of the DSPLx_CTARs are used to set the transfer attributes. Transfer attributes are set up during initialization and must not be changed between frames.

Refer to [Section 19.4.4, “Deserial Serial Interface \(DSI\) Configuration,”](#) for more details.

The CSI configuration is only available in master mode. In CSI configuration, the DSI data is transferred using DSI configuration transfer attributes and SPI data is transferred using the SPI configuration transfer attributes. In order for the bus slave to distinguish between DSI and SPI frames, the transfer attributes for the two types of frames must utilize different peripheral chip select signals.

Refer to [Section 19.4.5, “Combined Serial Interface \(CSI\) Configuration,”](#) for details.

19.4.1.2 Slave Mode

In slave mode the DSPI responds to transfers initiated by an SPI master. The DSPI operates as bus slave when the MSTR bit in the DSPLx_MCR is negated. The DSPI slave is selected by a bus master by having the slave's \overline{SS} asserted. In slave mode the SCK is provided by the bus master. All transfer attributes are controlled by the bus master, except the clock polarity, clock phase and the number of bits to transfer which must be configured in the DSPI slave to communicate correctly.

The SPI and DSI configurations are valid in slave mode. CSI configuration is not available in slave mode. In SPI slave mode the slave transfer attributes are set in the DSPI_x_CTAR0. In DSI slave mode the slave transfer attributes are set in the DSPI_x_CTAR1. In slave mode, for both SPI and DSI configurations, data is transferred MSB first. The LSBFE field of the associated CTAR is ignored.

19.4.1.3 Module Disable Mode

The module disable mode is used for MCU power management. The clock to the non-memory mapped logic in the DSPI is stopped while in module disable mode. The DSPI enters the module disable mode when the MDIS bit in DSPI_x_MCR is set.

Refer to [Section 19.4.10, “Power Saving Features,”](#) for more details on the module disable mode.

19.4.1.4 Debug Mode

The debug mode is used for system development and debugging. If the MCU enters debug mode while the FRZ bit in the DSPI_x_MCR is set, the DSPI stops all serial transfers and enters a stopped state. If the MCU enters debug mode while the FRZ bit is cleared, the DSPI behavior is unaffected and remains dictated by the module-specific mode and configuration of the DSPI. The DSPI enters debug mode when a debug request is asserted by an external controller.

Refer to [Figure 19-18](#) for a state diagram.

19.4.2 Start and Stop of DSPI Transfers

The DSPI has two operating states: STOPPED and RUNNING. The states are independent of DSPI configuration. The default state of the DSPI is STOPPED. In the STOPPED state no serial transfers are initiated in master mode and no transfers are responded to in slave mode. The STOPPED state is also a safe state for writing the various configuration registers of the DSPI without causing undetermined results. The TXRXS bit in the DSPI_x_SR is cleared in this state. In the RUNNING state, serial transfers take place. The TXRXS bit in the DSPI_x_SR is set in the RUNNING state.

[Figure 19-18](#) shows a state diagram of the start and stop mechanism.

Figure 19-18. DSPI Start and Stop State Diagram

The transitions are described in [Table 19-17](#).

Table 19-17. State Transitions for Start and Stop of DSPI Transfers

Transition #	Current State	Next State	Description
0	RESET	STOPPED	Generic power-on-reset transition
1	STOPPED	RUNNING	The DSPI starts (transitions from STOPPED to RUNNING) when all of the following conditions are true: <ul style="list-style-type: none"> • EOQF bit is clear • Debug mode is unselected or the FRZ bit is clear • HALT bit is clear
2	RUNNING	STOPPED	The DSPI stops (transitions from RUNNING to STOPPED) after the current frame for any one of the following conditions: <ul style="list-style-type: none"> • EOQF bit is set • Debug mode is selected and the FRZ bit is set • HALT bit is set

State transitions from RUNNING to STOPPED occur on the next frame boundary if a transfer is in progress, or on the next system clock cycle if no transfers are in progress.

19.4.3 Serial Peripheral Interface (SPI) Configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The DSPI is in SPI configuration when the DCONF field in the DSPIx_MCR is 0b00. The SPI frames can be from 4 to 16 bits long. The data to be transmitted can come from queues stored in RAM external to the DSPI. Host software or an eDMA controller can transfer the SPI data from the queues to a first-in first-out (FIFO) buffer. The received data is stored in entries in the receive FIFO (RX FIFO) buffer. Host software or an eDMA controller transfers the received data from the RX FIFO to memory external to the DSPI.

The FIFO buffer operations are described in [Section 19.4.3.4, “Transmit First In First Out \(TX FIFO\) Buffering Mechanism,”](#) and [Section 19.4.3.5, “Receive First In First Out \(RX FIFO\) Buffering Mechanism.”](#)

The interrupt and DMA request conditions are described in [Section 19.4.9, “Interrupts/DMA Requests.”](#)

The SPI configuration supports two module-specific modes; master mode and slave mode. The FIFO operations are similar for the master mode and slave mode. The main difference is that in master mode the DSPI initiates and controls the transfer according to the fields in the SPI command field of the TX FIFO entry. In slave mode the DSPI only responds to transfers initiated by a bus master external to the DSPI and the SPI command field of the TX FIFO entry is ignored.

19.4.3.1 SPI Master Mode

In SPI master mode the DSPI initiates the serial transfers by controlling the serial communications clock (SCK_x) and the peripheral chip select (PCS_x) signals. The SPI command field in the executing TX FIFO entry determines which CTARs are used to set the transfer attributes and which PCS_x signal to assert. The

command field also contains various bits that help with queue management and transfer protocol. The data field in the executing TX FIFO entry is loaded into the shift register and shifted out on the serial out (SOUTx) pin. In SPI master mode, each SPI frame to be transmitted has a command associated with it allowing for transfer attribute control on a frame by frame basis.

Refer to [Section 19.3.2.6, “DSPI PUSH TX FIFO Register \(DSPIx_PUSHR\),”](#) for details on the SPI command fields.

19.4.3.2 SPI Slave Mode

In SPI slave mode the DSPI responds to transfers initiated by an SPI bus master. The DSPI does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase and frame size must be set for successful communication with an SPI master. The SPI slave mode transfer attributes are set in the DSPIx_CTAR0.

19.4.3.3 FIFO Disable Operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO or RX FIFO. The DSPI operates as a double-buffered simplified SPI when the FIFOs are disabled. The TX and RX FIFOs are disabled separately. The TX FIFO is disabled by writing a 1 to the DIS_TXF bit in the DSPIx_MCR. The RX FIFO is disabled by writing a 1 to the DIS_RXF bit in the DSPIx_MCR.

The FIFO disable mechanisms are transparent to the user and to host software; transmit data and commands are written to the DSPIx_PUSHR and received data is read from the DSPIx_POPR. When the TX FIFO is disabled, the TFFF, TFUF, and TXCTR fields in DSPIx_SR behave as if there is a one-entry FIFO but the contents of the DSPIx_TXFRs and TXNXTPTR are undefined. When the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the DSPIx_SR behave as if there is a one-entry FIFO but the contents of the DSPIx_RXFRs and POPNXTPTR are undefined.

Disable the TX and RX FIFOs only if the FIFO must be disabled as a requirement of the application's operating mode. A FIFO must be disabled before it is accessed. Failure to disable a FIFO prior to a first FIFO access is not supported, and can result in incorrect results.

19.4.3.4 Transmit First In First Out (TX FIFO) Buffering Mechanism

The TX FIFO functions as a buffer of SPI data and SPI commands for transmission. The TX FIFO holds four entries, each consisting of a command field and a data field. SPI commands and data are added to the TX FIFO by writing to the DSPI push TX FIFO register (DSPIx_PUSHR). For more information on DSPIx_PUSHR. TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

Refer to [Section 19.3.2.6, “DSPI PUSH TX FIFO Register \(DSPIx_PUSHR\),”](#)

The TX FIFO counter field (TXCTR) in the DSPI status register (DSPIx_SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time the DSPI_PUSHR is written or SPI data is transferred into the shift register from the TX FIFO.

Refer to [Section 19.3.2.4, “DSPI Status Register \(DSPIx_SR\)”](#) for more information on DSPIx_SR.

The TXNXTPTR field indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR contains the positive offset from DSPIx_TXFR0 in number of 32-bit registers. For example, TXNXTPTR equal to two means that the DSPIx_TXFR2 contains the SPI data and command for the next transfer. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register.

19.4.3.4.1 Filling the TX FIFO

Host software or the eDMA controller can add (push) entries to the TX FIFO by writing to the DSPIx_PUSHR. When the TX FIFO is not full, the TX FIFO fill flag (TFFF) in the DSPIx_SR is set. The TFFF bit is cleared when the TX FIFO is full and the eDMA controller indicates that a write to DSPIx_PUSHR is complete or alternatively by host software writing a 1 to the TFFF in the DSPIx_SR. The TFFF can generate a DMA request or an interrupt request.

Refer to [Section 19.4.9.2, “Transmit FIFO Fill Interrupt or DMA Request \(TFFF\),”](#) for details.

The DSPI ignores attempts to push data to a full TX FIFO; that is, the state of the TX FIFO is unchanged. No error condition is indicated.

19.4.3.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO counter is decremented by one. At the end of a transfer, the TCF bit in the DSPIx_SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a 1 to the CLR_TXF bit in DSPIx_MCR.

If an external SPI bus master initiates a transfer with a DSPI slave while the slave’s DSPI TX FIFO is empty, the transmit FIFO underflow flag (TFUF) in the slave’s DSPIx_SR is set.

Refer to [Section 19.4.9.4, “Transmit FIFO Underflow Interrupt Request \(TFUF\),”](#) for details.

19.4.3.5 Receive First In First Out (RX FIFO) Buffering Mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds four received SPI data frames. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data is removed (popped) from the RX FIFO by reading the DSPIx_POPR register. RX FIFO entries can only be removed from the RX FIFO by reading the DSPIx_POPR or by flushing the RX FIFO.

Refer to [Section 19.3.2.7, “DSPI POP RX FIFO Register \(DSPIx_POPR\)”](#) for more information on the DSPIx_POPR.

The RX FIFO counter field (RXCTR) in the DSPI status register (DSPIx_SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the DSPIx_POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the DSPIx_SR points to the RX FIFO entry that is returned when the DSPIx_POPR is read. The POPNXTPTR contains the positive, 32-bit word offset from DSPIx_RXFR0. For example, POPNXTPTR equal to two means that the DSPIx_RXFR2 contains the received SPI data

that is returned when DSPIx_POPR is read. The POPNXTPTR field is incremented every time the DSPIx_POPR is read. POPNXTPTR rolls over every four frames on the MCU.

19.4.3.5.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO the RX FIFO counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the DSPIx_SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the DSPIx_MCR, the data from the transfer that generated the overflow is ignored or put in the shift register. If the ROOE bit is set, the incoming data is put in the shift register. If the ROOE bit is cleared, the incoming data is ignored.

19.4.3.5.2 Draining the RX FIFO

Host software or the eDMA can remove (pop) entries from the RX FIFO by reading the DSPIx_POPR. A read of the DSPIx_POPR decrements the RX FIFO counter by one. Attempts to pop data from an empty RX FIFO are ignored, the RX FIFO counter remains unchanged. The data returned from reading an empty RX FIFO is undetermined.

Refer to [Section 19.3.2.7, “DSPI POP RX FIFO Register \(DSPIx_POPR\)”](#) for more information on DSPIx_POPR.

When the RX FIFO is not empty, the RX FIFO drain flag (RFDF) in the DSPIx_SR is set. The RFDF bit is cleared when the RX_FIFO is empty and the eDMA controller indicates that a read from DSPIx_POPR is complete; alternatively the RFDF bit can be cleared by the host writing a 1 to it.

19.4.4 Deserial Serial Interface (DSI) Configuration

The DSI configuration supports pin count reduction by serializing parallel input signals or register bits and shifting them out in an SPI-like protocol. The received serial frames are converted to a parallel form (deserialized) and placed on the parallel output signals or in a register. The various features of the DSI configuration are set in the DSPIx_DSICR. For more information on the DSPIx_DSICR. The DSPI is in DSI configuration when the DCONF field in the DSPIx_MCR is 0b01.

Refer to [Section 19.4.7, “Transfer Formats”](#) for a description of the timing and transfer protocol.

Refer to [Section 19.3.2.10, “DSPI DSI Configuration Register \(DSPIx_DSICR\).”](#)

The DSI frames can be from 4 to 16 bits long. With multiple transfer operation (MTO), the DSPI supports serial chaining of DSPI modules within the MCU to create DSI frames consisting of concatenated bits from multiple DSPIs. The DSPI also supports parallel chaining allowing several DSPIs and off-chip SPI devices to share the same serial communications clock (SCK) and peripheral chip select (PCS) signals.

Refer to [Section 19.4.4.7, “Multiple Transfer Operation \(MTO\),”](#) for details on the serial and parallel chaining support.

19.4.4.1 DSI Master Mode

In DSI master mode the DSPI initiates and controls the DSI transfers. The DSI master has four different conditions that can initiate a transfer:

- Continuous
- Change in data
- Trigger signal
- Trigger signal combined with a change in data

The four transfer initiation conditions are described in [Section 19.4.4.5, “DSI Transfer Initiation Control.”](#) Transfer attributes are set during initialization. The DSICTAS field in the DSPLx_DSICR determines which of the DSPLx_CTARs controls the transfer attributes.

19.4.4.2 DSI Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by an SPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers. Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPLx_CTAR1.

If the CID bit in the DSPLx_DSICR is set and the data in the DSPLx_COMPR differs from the selected source of the serialized data, the slave DSPI asserts the $\overline{\text{MTRIG}}$ signal. If the slave's internal hardware trigger signal is asserted and the TRRE is set, the slave DSPI asserts $\overline{\text{MTRIG}}$. These features are included to support chaining of several DSPI. Details about the $\overline{\text{MTRIG}}$ signal are found in [Section 19.4.4.7, “Multiple Transfer Operation \(MTO\).”](#)

19.4.4.3 DSI Serialization

In the DSI configuration, 4 to 16 bits can be serialized using two different sources. The TXSS bit in the DSPLx_DSICR selects between the DSPLx_SDR and DSPLx_AS DR as the source of serialized data. Refer to [Section 19.3.2.11, “DSPI DSI Serialization Data Register \(DSPLx_SDR\),”](#) and [Section 19.3.2.12, “DSPI DSI Alternate Serialization Data Register \(DSPLx_AS DR\),”](#) for more details. The DSPLx_SDR holds the latest parallel input signal values which is sampled at every rising edge of the system clock. The DSPLx_AS DR is written by host software and used as an alternate source of serialized data.

A copy of the last DSI frame shifted out of the shift register is stored in the DSPLx_COMPR. This register provides added visibility for debugging and it serves as a reference for transfer initiation control.

[Section 19.3.2.13, “DSPI DSI Transmit Comparison Register \(DSPLx_COMPR\),”](#) contains details on the DSPLx_COMPR.

Figure 19-19 shows the DSI serialization logic.

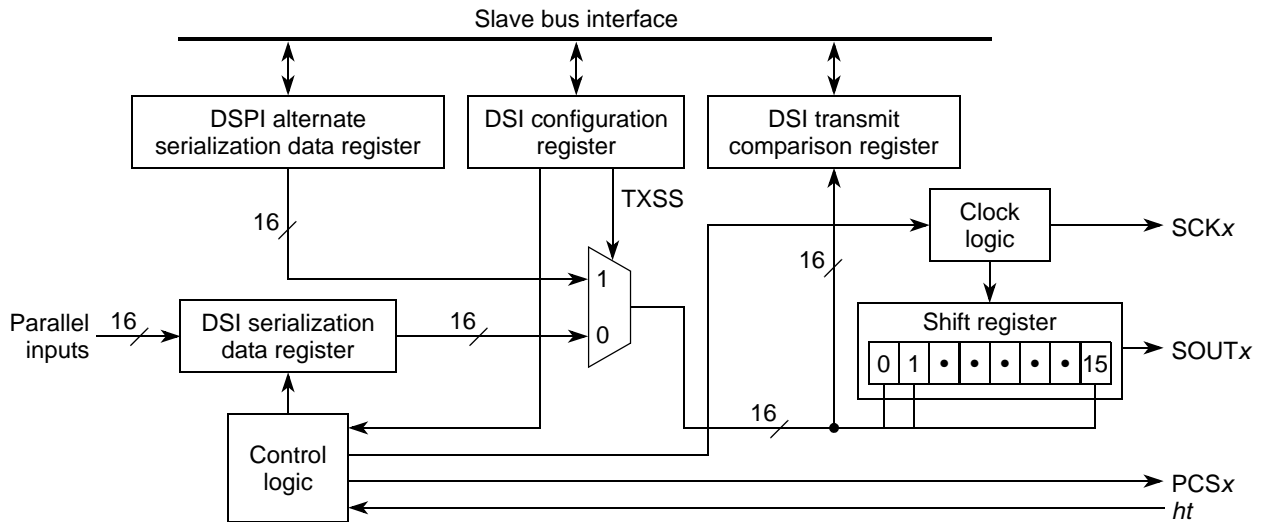

Figure 19-19. DSI Serialization Diagram

19.4.4.4 DSI Deserialization

When all bits in a DSI frame have been shifted in, the frame is copied to the DSPIx_DDR. This register presents the deserialized data as parallel output signal values. The DSPIx_DDR is memory mapped to allow host software to read the deserialized data directly. Figure 19-20 shows the DSI deserialization logic. for more information on the DSPIx_DDR.

Refer to Section 19.3.2.14, “DSPI DSI Deserialization Data Register (DSPIx_DDR).”

Figure 19-20. DSI Deserialization Diagram

19.4.4.5 DSI Transfer Initiation Control

Data transfers for a master DSPI in DSI configuration are initiated by a condition. When chaining DSPIs, the master and all slaves must be configured for the transfer initiation. The transfer initiation conditions are selected by the TRRE and CID bits in the DSPIx_DSICR.

Table 19-18 lists the four transfer initiation conditions.

Table 19-18. DSI Data Transfer Initiation Control

DSPI _x _DSICR Bits		Type of Transfer Initiation Control
TRRE	CID	
0	0	Continuous
0	1	Change in data
1	0	Triggered
1	1	Triggered or change in data

19.4.4.5.1 Continuous Control

For continuous control, the initiation of a transfer is based on the baud rate at which data is transferred between the DSPI and the external device. The baud rate is set in the DSPI_x_CTAR selected by the DSICTAS field in the DSPI_x_DSICR. A new DSI frame shifts out when the previous transfer cycle has completed and the delay after transfer (t_{DT}) has elapsed.

19.4.4.5.2 Change In Data Control

For change in data control, a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in the DSPI_x_COMPR. When the data in the DSPI_x_SDR or the DSPI_x_ASDR is different from the data in the DSPI_x_COMPR, a new DSI frame is transmitted. The TXSS bit in the DSPI_x_DSICR selects which register the DSPI_x_COMPR is compared to. The \overline{MTRIG} output signal is asserted every time a change in data is detected.

19.4.4.5.3 Triggered Control

For triggered control, initiation of a transfer is controlled by the internal hardware trigger signal (*ht*). The TPOL bit in the DSPI_x_DSICR selects the active edge of *ht*. For *ht* to have any affect, the TRRE bit in the DSPI_x_DSICR must be set.

19.4.4.5.4 Triggered or Change In Data Control

For triggered or change in data control, initiation of a transfer is controlled by the *ht* signal or by the detection of a change in data to be serialized.

19.4.4.6 DSPI Connections to eTPUA, eMIOS and SIU

The three DSPI blocks connect to the input and output channels of the eTPUs and the eMIOS. The MCU connects to eTPUA, eMIOS, and SIU. Some of the DSPI outputs connect to the external interrupt input multiplexing subblock in the SIU. Refer to [Section 6.4.3, “External Interrupt,”](#) and [Section 18.4.3.4, “External Trigger Event Detection,”](#) for details on how the DSPI deserialized outputs can be used to trigger external interrupt requests and [Section 17.3.2, “Output and Input Channel Signals”](#) for a discussion on eTPU connections.

19.4.4.6.1 DSPI B Connectivity

The DSPI B connects to the eMIOS, eTPUA, and SIU as shown in Figure 19-21.

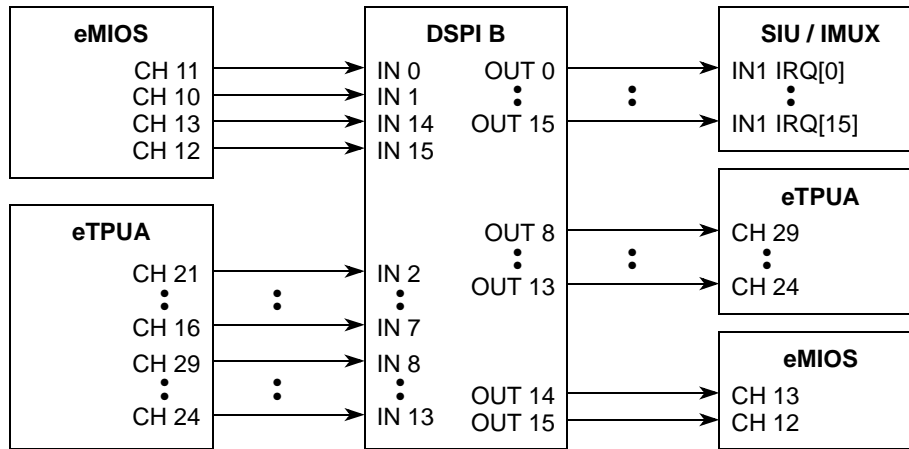

Figure 19-21. DSPI_B Connectivity

Table 19-19 lists the DSPI B connections.

Table 19-19. DSPI B Connectivity Table

Connected to:	DSPI B IN[n]	DSPI B OUT[n]	Connected to:
eMIOS output channel 11	0	0	Input 1 on IMUX for external $\overline{IRQ}[0]$
eMIOS output channel 10	1	1	Input 1 on IMUX for external $\overline{IRQ}[1]$

eTPUA output channel 25	14	14	eMIOS input channel 15, Input 3 on IMUX for external $\overline{\text{IRQ}}[12]$
eTPUA output channel 24	15	15	eMIOS input channel 14, Input 3 on IMUX for external $\overline{\text{IRQ}}[13]$

19.4.4.7 Multiple Transfer Operation (MTO)

In DSI configuration the MTO feature allows for multiple DSPIs within the MCU to be chained together in a parallel or serial configuration. The parallel chaining allows multiple DSPIs internal to the MCU and multiple SPI devices external to the MCU to share SCK and PCS signals thereby saving pins. The serial chaining allows bits from multiple DSPIs to be concatenated into a single DSI frame. MTO is enabled by setting the MTOE bit in the DSPIx_DSICR.

In parallel and serial chaining there is one bus master and multiple bus slaves. The bus master initiates and controls the transfers, but the DSPI slaves generate trigger signals for the bus DSPI master when an internal condition in the slave warrants a transfer. The DSPI slaves also propagate triggers from other slaves to the master. When a DSPI slave detects a trigger signal on its *ht* input, the slave generates a trigger signal on the $\overline{\text{MTRIG}}$ output.

The SIU_DISR must be configured to use serial or parallel chaining.

19.4.4.7.1 Internal Muxing/SIU Support for Serial and Parallel Chaining

To support MTO, each DSPI in the device has multiplexers on the SIN_x, SS_x, SCK_x, and *ht* inputs. The internal multiplexers are controlled by registers in the SIU block.

Refer to [Section 6.4.5.3, “Multiplexed Inputs for DSPI Multiple Transfer Operation.”](#)

Figure 19-24 shows DSPI B and the multiplexers in the IMUX subblock of the SIU. The SOUT_x, $\overline{\text{MTRIG}}$, SCK_x and PCS_{x0} outputs from the other two DSPIs connect to the multiplexers on the DSPI B inputs. DSPI B, DSPI C and DSPI D have similar multiplexers on their inputs.

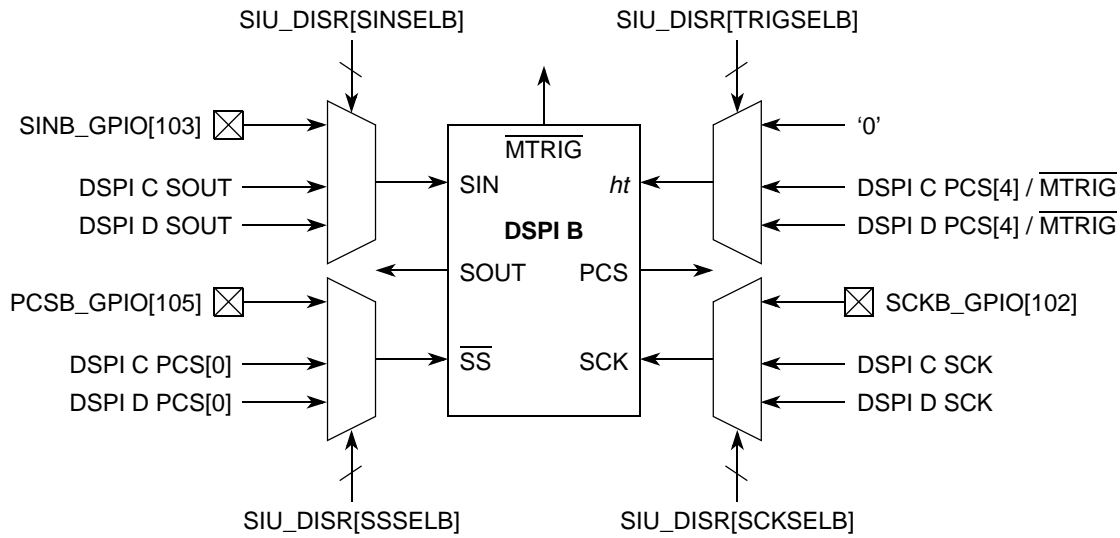

Figure 19-24. DSPI Input Select Muxes

The source for the SIN_x input of a DSPI can be a pin or the $SOUT_x$ of any of the other two DSPIs. The source for the \overline{SS}_x input of a DSPI can be a pin or the $PCS_x[0]$ signal from any of the other DSPIs. The source for the SCK_x input of a DSPI can be a pin or the SCK_x output of any of the other DSPIs. The source for the hardware trigger (ht) input can be the \overline{MTRIG} signal from any of the other DSPIs. The DSPI input select register (SIU_DSR) selects the source for each DSPI SIN_x , \overline{SS}_x , SCK_x , and ht signal individually.

19.4.4.7.2 Parallel Chaining

Parallel chaining allows the PCS_x and SCK_x signals from a master DSPI to be shared by internal slave DSPIs and external slave SPI devices. Signal sharing reduces DSPI pin utilization. An example of a parallel chain is shown in [Figure 19-25](#).

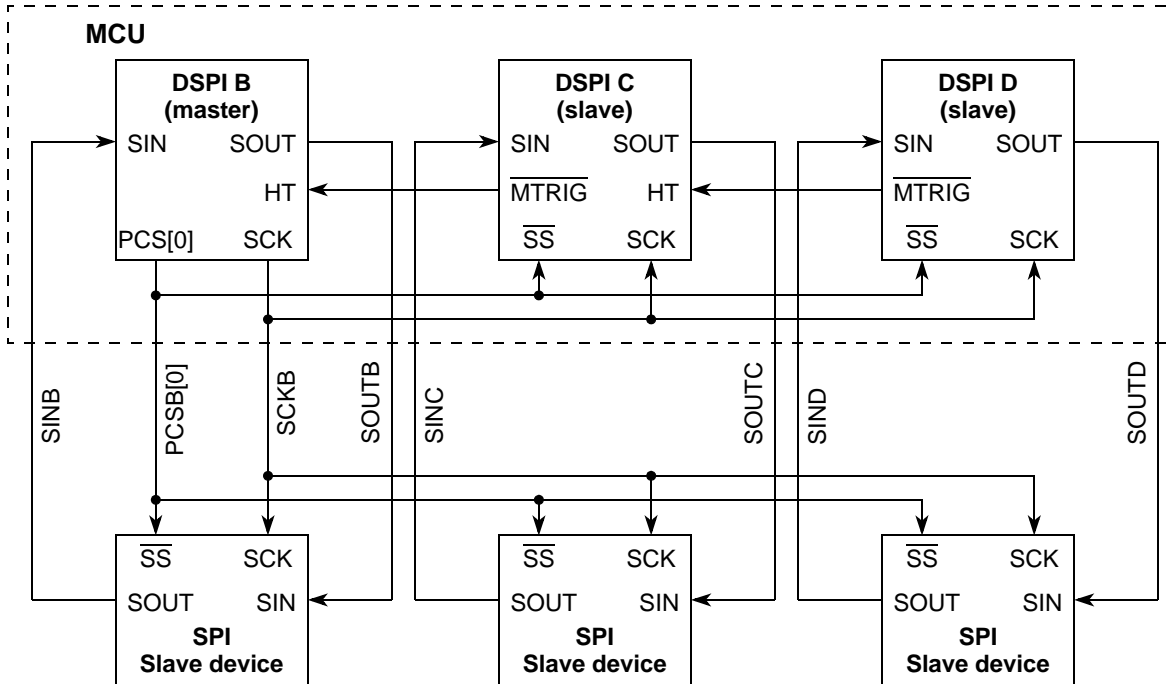

Figure 19-25. Example of Parallel Chaining of DSPIs

In the parallel chaining example, the SOUT_x and SIN_x of the DSPIs connect to separate external SPI devices. All internal and external SPI modules share PCS_x and SCK_x signals. DSPI B controls and initiates all transfers, but the DSPI slaves each have a trigger output signal MTRIG that indicates to DSPI B that a trigger condition has occurred in the DSPI slaves.

When the slave DSPI has a change in data to be serialized, it asserts the MTRIG signal that propagates to DSPI B which initiates the transfer.

The MTOCNT field in the DSPI_x_DSICR must be written with the number of bits to be transferred. In parallel chaining the number written to MTOCNT must match the FMSZ field in the selected DSPI_x_CTAR.

19.4.4.7.3 Serial Chaining

Serial chaining allows transfers of DSI frames consisting of concatenated bits from multiple DSPIs. The concatenated frames can be from 8- to 64-bits long. Figure 19-26 shows an example of how the modules can be connected.

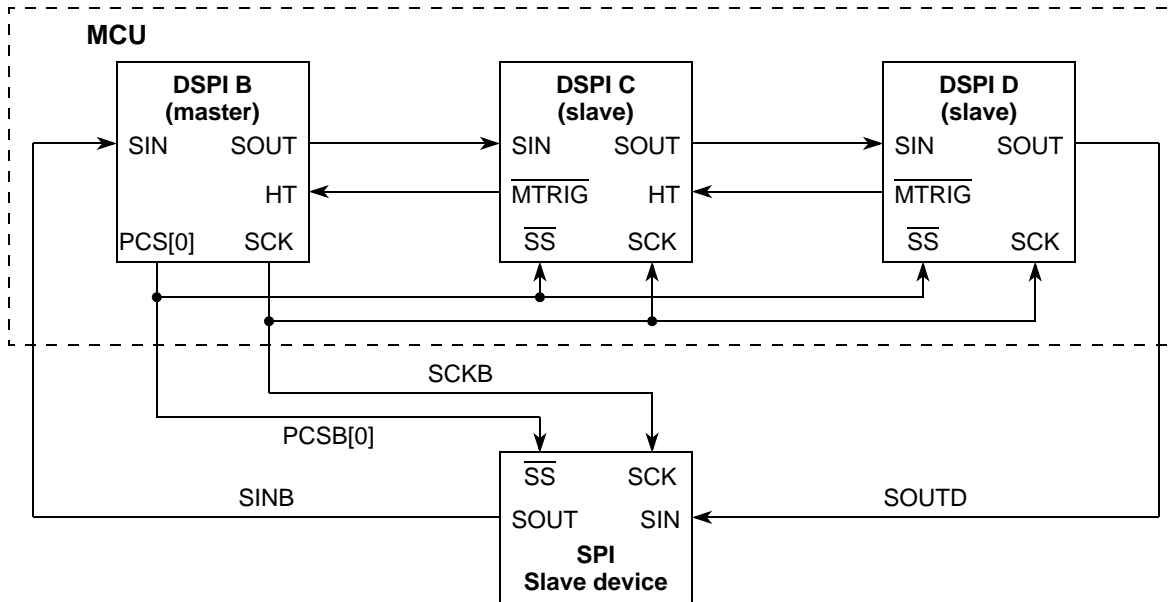

Figure 19-26. Example of Serial Chaining of DSPIs

In the MCU (master), the SOUT of DSPI B is connected to the SIN of DSPI C (slave). The SOUT of the DSPI C (slave) is connected to the SIN input of the DSPI D and so on (slave). The SOUT of the last on-chip DSPI slave is connected to the SIN of the external SPI slave. The SOUT of the external SPI slave is connected to the SIN of DSPI B master.

The DSPI B master controls and initiates all transfers, but the slave DSPIs use the trigger output signal $\overline{\text{MTRIG}}$ to indicate to the DSPI B master that a trigger condition has occurred. When an on-chip DSPI slave has a change in data to be serialized it can assert the $\overline{\text{MTRIG}}$ signal to the DSPI master which initiates the transfer. When a DSPI slave has its ht signal asserted, its $\overline{\text{MTRIG}}$ signal asserts and propagates trigger signals from other DSPI slaves to the DSPI master.

The MTOCNT field in the DSPIx_DSICR must be written with the total number of bits to be transferred. The MTOCNT field must equal the sum of all FMSZ fields in the selected DSPIx_CTARs for the DSPI master and all DSPI slaves. For example if one 16-bit DSI frame is created by concatenating 8 bits from the DSPI master, and 4 bits from each of the DSPI slaves in Figure 19-26, the DSPI master's frame size must be set to eight in the FMSZ field, and the DSPI slaves' frame size must be set to four. The largest DSI frame supported by the MTOCNT field is 48 bits. Any number of DSPIs can be connected together to concatenate DSI frames, as long as each DSPI transfers a minimum of 4 bits and a maximum of 16 bits and the total size of the concatenated frame is less than or equal to 48 bits long.

19.4.5 Combined Serial Interface (CSI) Configuration

In master mode, the CSI configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis. CSI configuration allows interleaving of DSI data frames from the parallel input signals (from the eTPU or eMIOS) with SPI commands and data from the TX FIFO. The data returned from the bus slave is either used to drive the parallel output signals (to the eTPU or eMIOS) or is stored in the RX FIFO. CSI configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI configuration when the DCONF field in the DSPLx_MCR is 0b10. [Figure 19-27](#) shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

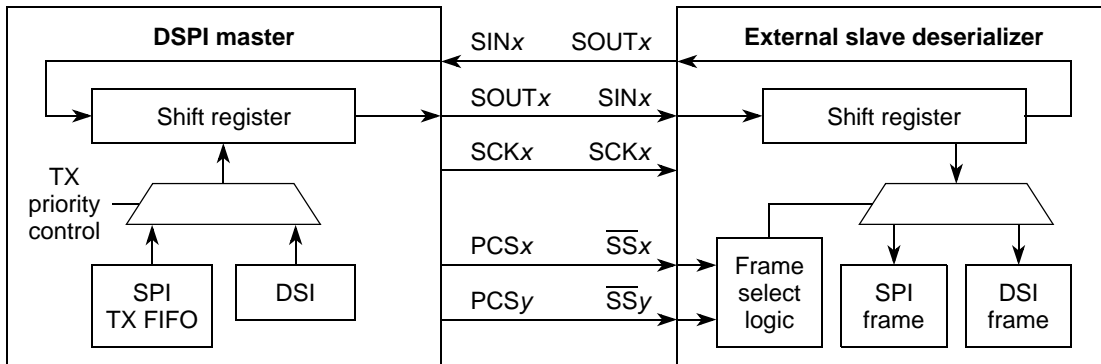

Figure 19-27. Example of System using DSPI in CSI Configuration

In CSI configuration the DSPI transfers DSI data based on [Section 19.4.4.5, “DSI Transfer Initiation Control.”](#) When there are SPI commands in the TX FIFO, the SPI data has priority over the DSI frames. When the TX FIFO is empty, DSI transfer resumes.

Two peripheral chip select signals indicate whether DSI data or SPI data is transmitted. You must configure the DSPI so the CTARs for the DSI data and SPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy. The CSI configuration is only supported in master mode.

Data returned from the external slave while a DSI frame is transferred is placed on the parallel output signals. Data returned from the external slave while an SPI frame is transferred is moved to the RX FIFO. The TX FIFO and RX FIFO are fully functional in CSI mode.

19.4.5.1 CSI Serialization

Serialization in the CSI configuration is similar to serialization in DSI configuration. The transfer attributes for SPI frames are determined by the DSPLx_CTAR selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPLx_CTAR selected by the DSICTAS field in the DSPLx_DSICR.

Figure 19-28 shows the CSI serialization logic.

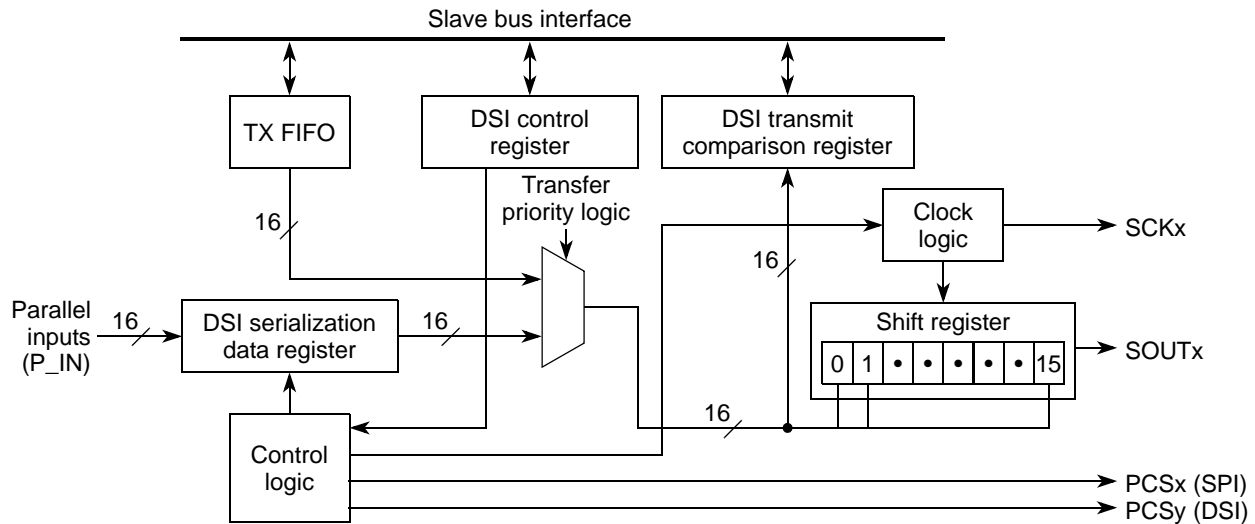

Figure 19-28. CSI Serialization Diagram

The parallel inputs signal states are latched into the DSPI_x_SDR on the rising edge of every system clock and serialized based on the transfer initiation control settings in the DSPI_x_DSICR. For more information on the DSPI_x_SDR, SPI frames written to the TX FIFO have priority over DSI data from the DSPI_x_SDR and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in the DSPI_x_COMPR. The transfer priority logic selects the source of the serialized data and asserts the chip select signal.

Refer to [Section 19.3.2.11, “DSPI DSI Serialization Data Register \(DSPI_x_SDR\).”](#)

19.4.5.2 CSI Deserialization

The deserialized frames in CSI configuration go into the DSPI_x_SDR or the RX FIFO based on the transfer priority logic. When DSI frames are transferred the returned frames are deserialized and latched into the DSPI_x_DDR. When SPI frames are transferred the returned frames are deserialized and written to the RX FIFO.

Figure 19-29 shows the CSI deserialization logic.

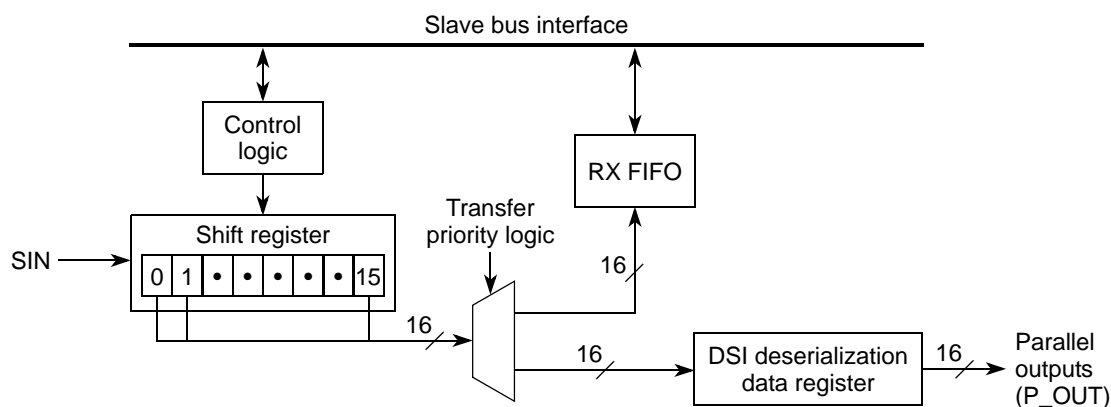

Figure 19-29. CSI Deserialization Diagram

19.4.6 DSPI Baud Rate and Clock Delay Generation

The SCK_x frequency and the delay values for serial transfer are generated by dividing the system clock frequency by a prescaler and a scaler with the option of doubling the baud rate.

Figure 19-30 shows conceptually how the SCK signal is generated.

Figure 19-30. Communications Clock Prescalers and Scalers

19.4.6.1 Baud Rate Generator

The baud rate is the frequency of the serial communication clock (SCK_x). The system clock is divided by a baud rate prescaler (defined by DSPI_x_CTAR[PBR]) and baud rate scaler (defined by DSPI_x_CTAR[BR]) to produce SCK_x with the possibility of doubling the baud rate. The DBR, PBR, and BR fields in the DSPI_x_CTARs select the frequency of SCK_x using the following formula:

$$\text{SCK baud rate} = \frac{f_{\text{sys}}}{\text{PBRPrescalerValue}} \times \frac{1 + \text{DBR}}{\text{BRScalerValue}}$$

Table 19-22 shows an example of a computed baud rate.

Table 19-22. Baud Rate Computation Example

f _{sys}	PBR	Prescaler Value	BR	Scaler Value	DBR Value	Baud Rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/sec
20 MHz	0b00	2	0b0000	2	1	10 Mb/sec

19.4.6.2 PCS to SCK Delay (t_{csc})

The PCS_x to SCK_x delay is the length of time from assertion of the PCS_x signal to the first SCK_x edge. Refer to [Figure 19-32](#) for an illustration of the PCS_x to SCK_x delay. The PCSSCK and CSSCK fields in the DSPI_x_CTAR_n registers select the PCS_x to SCK_x delay, and the relationship is expressed by the following formula:

$$t_{csc} = \frac{1}{f_{sys}} \times PCSSCK \times CSSCK$$

[Table 19-23](#) shows an example of the computed PCS to SCK delay.

Table 19-23. PCS to SCK Delay Computation Example

PCSSCK	Prescaler Value	CSSCK	Scaler Value	f _{sys}	PCS to SCK Delay
0b01	3	0b0100	32	100 MHz	0.96 μs

19.4.6.3 After SCK Delay (t_{asc})

The after SCK_x delay is the length of time between the last edge of SCK_x and the negation of PCS_x. Refer to [Figure 19-32](#) and [Figure 19-33](#) for illustrations of the after SCK_x delay. The PASC and ASC fields in the DSPI_x_CTAR_n registers select the after SCK delay. The relationship between these variables is given in the following formula:

$$t_{asc} = \frac{1}{f_{sys}} \times PASC \times ASC$$

[Table 19-24](#) shows an example of the computed after SCK delay.

Table 19-24. After SCK Delay Computation Example

PASC	Prescaler Value	ASC	Scaler Value	f _{sys}	After SCK Delay
0b01	3	0b0100	32	100 MHz	0.96 μs

19.4.6.4 Delay after Transfer (t_{dt})

The delay after transfer is the length of time between negation of the PCS_x signal for a frame and the assertion of the PCS_x signal for the next frame. The PDT and DT fields in the DSPI_x_CTAR_n registers select the delay after transfer.

Refer to [Figure 19-32](#) for an illustration of the delay after transfer.

The following formula expresses the PDT/DT/delay after transfer relationship:

$$t_{dt} = \frac{1}{f_{sys}} \times PDT \times DT$$

Table 19-25 shows an example of the computed delay after transfer.

Table 19-25. Delay after Transfer Computation Example

PDT	Prescaler Value	DT	Scaler Value	f _{sys}	Delay after Transfer
0b01	3	0b1110	32768	100 MHz	0.98 ms

19.4.6.5 Peripheral Chip Select Strobe Enable ($\overline{\text{PCSS}}$)

The $\overline{\text{PCSS}}$ signal provides a delay to allow the PCS_x signals to settle after transitioning thereby avoiding glitches. When the DSPI is in master mode and PCSSE bit is set in the DSPLx_MCR, $\overline{\text{PCSS}}$ provides a signal for an external demultiplexer to decode the PCS_x[0:4] signals into as many as 32 glitch-free PCS_x signals.

Figure 19-31 shows the timing of the $\overline{\text{PCSS}}$ signal relative to PCS signals.

Figure 19-31. Peripheral Chip Select Strobe Timing

The delay between the assertion of the PCS_x signals and the assertion of $\overline{\text{PCSS}}$ is selected by the PCSSCK field in the DSPLx_CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_{\text{SYS}}} \times \text{PCSSCK}$$

At the end of the transfer the delay between $\overline{\text{PCSS}}$ negation and PCS_x negation is selected by the PASC field in the DSPLx_CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_{\text{SYS}}} \times \text{PASC}$$

Table 19-26 shows an example of the computed t_{PCSSCK} delay.

Table 19-26. Peripheral Chip Select Strobe Assert Computation Example

PCSSCK	Prescaler	f _{sys}	Delay before Transfer
0b11	7	100 MHz	70.0 ns

Table 19-27 shows an example of the computed the t_{PASC} delay.

Table 19-27. Peripheral Chip Select Strobe Negate Computation Example

PASC	Prescaler	f_{SYS}	Delay after Transfer
0b11	7	100 MHz	70.0 ns

19.4.7 Transfer Formats

The SPI serial communication is controlled by the serial communications clock (SCK x) signal and the PCS x signals. The SCK x signal provided by the master device synchronizes shifting and sampling of the data by the SIN x and SOUT x pins. The PCS x signals serve as enable signals for the slave devices.

When the DSPI is the bus master, the CPOL and CPHA bits in the DSPI clock and transfer attributes registers (DSPI x_CTARn) select the polarity and phase of the serial clock, SCK x . The polarity bit selects the idle state of the SCK x . The clock phase bit selects if the data on SOUT x is valid before or on the first SCK x edge.

When the DSPI is the bus slave, CPOL and CPHA bits in the DSPI x_CTAR0 (SPI slave mode) or DSPI x_CTAR1 (DSI slave mode) select the polarity and phase of the serial clock. Even though the bus slave does not control the SCK signal, clock polarity, clock phase and number of bits to transfer must be identical for the master device and the slave device to ensure proper transmission.

The DSPI supports four different transfer formats:

- Classic SPI with CPHA = 0
- Classic SPI with CPHA = 1
- Modified transfer format with CPHA = 0
- Modified transfer format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The DSPI can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the DSPI x_MCR selects between classic SPI format and modified transfer format. The classic SPI formats are described in [Section 19.4.7.1, “Classic SPI Transfer Format \(CPHA = 0\)”](#) and [Section 19.4.7.2, “Classic SPI Transfer Format \(CPHA = 1\)”](#). The modified transfer formats are described in [Section 19.4.7.3, “Modified SPI/DSI Transfer Format \(MTFE = 1, CPHA = 0\)”](#) and [Section 19.4.7.4, “Modified SPI/DSI Transfer Format \(MTFE = 1, CPHA = 1\)”](#).

In the SPI and DSI configurations, the DSPI provides the option of keeping the PCS signals asserted between frames. Refer to [Section 19.4.7.5, “Continuous Selection Format”](#) for details.

19.4.7.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in Figure 19-32 is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN_x pins on the odd-numbered SCK_x edges and change the data on their $SOUT_x$ pins on the even-numbered SCK_x edges.

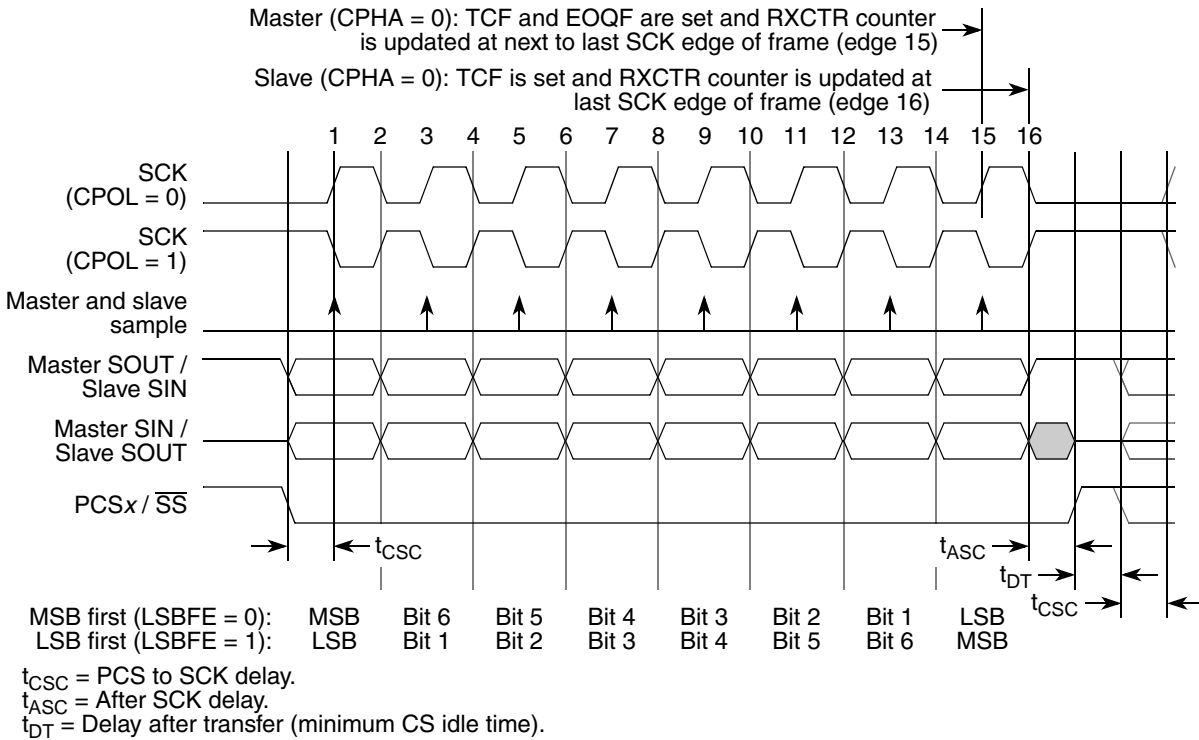

Figure 19-32. DSPI Transfer Timing Diagram (MTFE = 0, CPHA = 0, FMSZ = 8)

The master initiates the transfer by placing its first data bit on the $SOUT_x$ pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its $SOUT_x$ pin. After the t_{CSC} delay has elapsed, the master outputs the first edge of SCK_x . This is the edge used by the master and slave devices to sample the first input data bit on their serial data input signals. At the second edge of the SCK_x the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN_x pins on the odd-numbered clock edges and changes the data on their $SOUT_x$ pins on the even-numbered clock edges. After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

For the $CPHA = 0$ condition of the master, TCF and EOQF are set and the RXCTR counter is updated at the next to last serial clock edge of the frame (edge 15) of Figure 19-32.

For the $CPHA = 0$ condition of the slave, TCF is set and the RXCTR counter is updated at the last serial clock edge of the frame (edge 16) of Figure 19-32.

19.4.7.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in [Figure 19-33](#) is used to communicate with peripheral SPI slave devices that require the first SCK_x edge before the first data bit becomes available on the slave SOUT pin. In this format the master and slave devices change the data on their SOUT_x pins on the odd-numbered SCK_x edges and sample the data on their SIN_x pins on the even-numbered SCK_x edges.

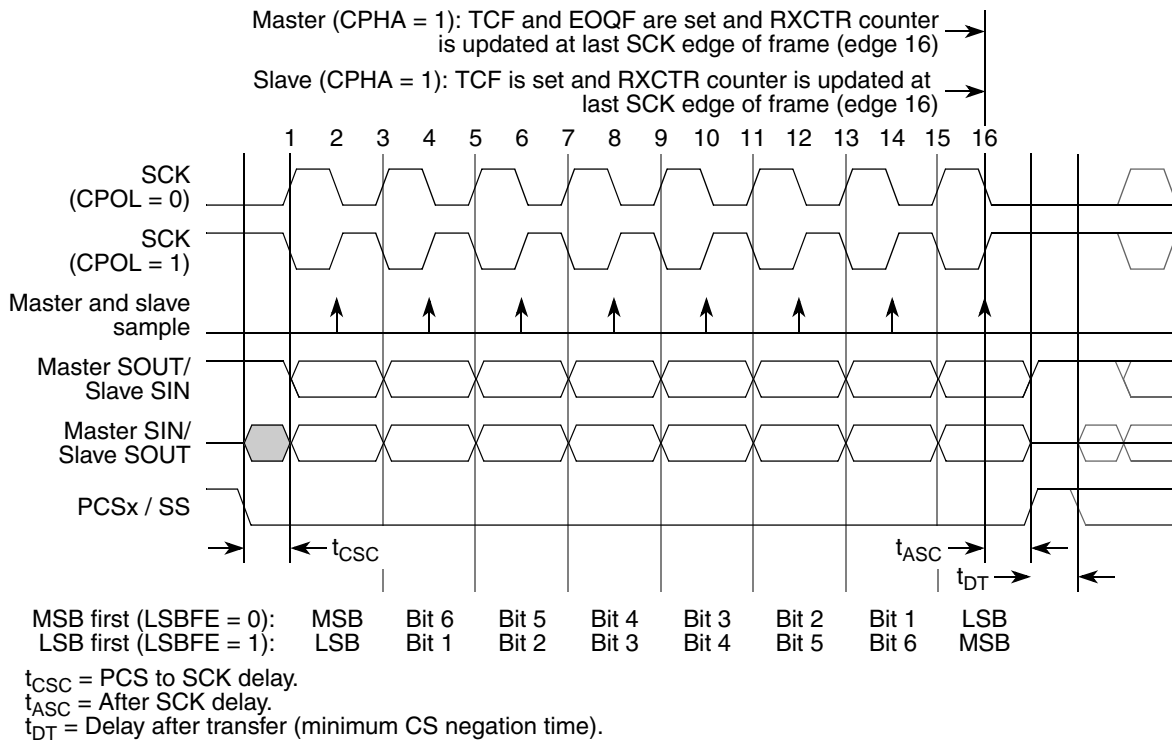

Figure 19-33. DSPI Transfer Timing Diagram (MTFE = 0, CPHA = 1, FMSZ = 8)

The master initiates the transfer by asserting the PCS_x signal to the slave. After the t_{CSC} delay has elapsed, the master generates the first SCK_x edge and at the same time places valid data on the master SOUT_x pin. The slave responds to the first SCK_x edge by placing its first data bit on its slave SOUT_x pin.

At the second edge of the SCK_x the master and slave sample their SIN_x pins. For the rest of the frame the master and the slave change the data on their SOUT_x pins on the odd-numbered clock edges and sample their SIN_x pins on the even-numbered clock edges. After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS_x signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

For CPHA = 1 the master EOQF and TCF and slave TCF are set at the last serial clock edge (edge 16) of [Figure 19-33](#). For CPHA = 1 the master and slave RXCTR counters are updated on the same clock edge.

19.4.7.3 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)

In this modified transfer format both the master and the slave sample later in the SCK period than in classic SPI mode to allow for delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

NOTE

For the modified transfer format to operate correctly, you must thoroughly analyze the SPI link timing budget.

The master and the slave place data on the SOUT_x pins at the assertion of the PCS_x signal. After the PCS_x to SCK_x delay has elapsed the first SCK_x edge is generated. The slave samples the master SOUT_x signal on every odd numbered SCK_x edge. The slave also places new data on the slave SOUT_x on every odd numbered clock edge.

The master places its second data bit on the SOUT_x line one system clock after odd numbered SCK_x edge. The point where the master samples the slave SOUT_x is selected by writing to the SMPL_PT field in the DSPL_x_MCR. [Table 19-28](#) lists the number of system clock cycles between the active edge of SCK_x and the master sample point for different values of the SMPL_PT bit field. The master sample point can be delayed by one or two system clock cycles.

Table 19-28. Delayed Master Sample Point

SMPL_PT	Number of System Clock Cycles between Odd-numbered Edge of SCK and Sampling of SIN
00	0
01	1
10	2
11	Invalid value

Figure 19-34 shows the modified transfer format for $CPHA = 0$. Only the condition where $CPOL = 0$ is illustrated. The delayed master sample points are indicated with a lighter shaded arrow.

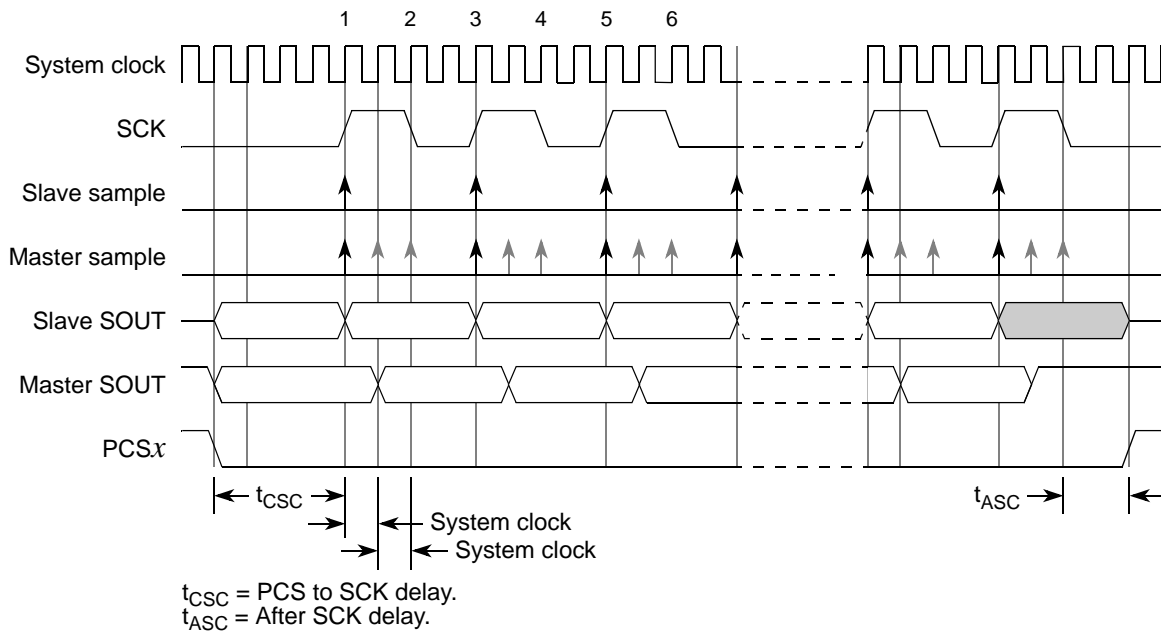

Figure 19-34. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{SCK} = f_{SYS} / 4$)

19.4.7.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the 3rd SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge is visible on the master SCK pin during the sampling of the last bit. The SCK to PCS delay must be greater or equal to half of the SCK period.

NOTE

For the modified transfer format to operate correctly, you must thoroughly analyze the SPI link timing budget.

Figure 19-35 shows the modified transfer format for CPHA = 1. Only the condition where CPOL = 0 is described.

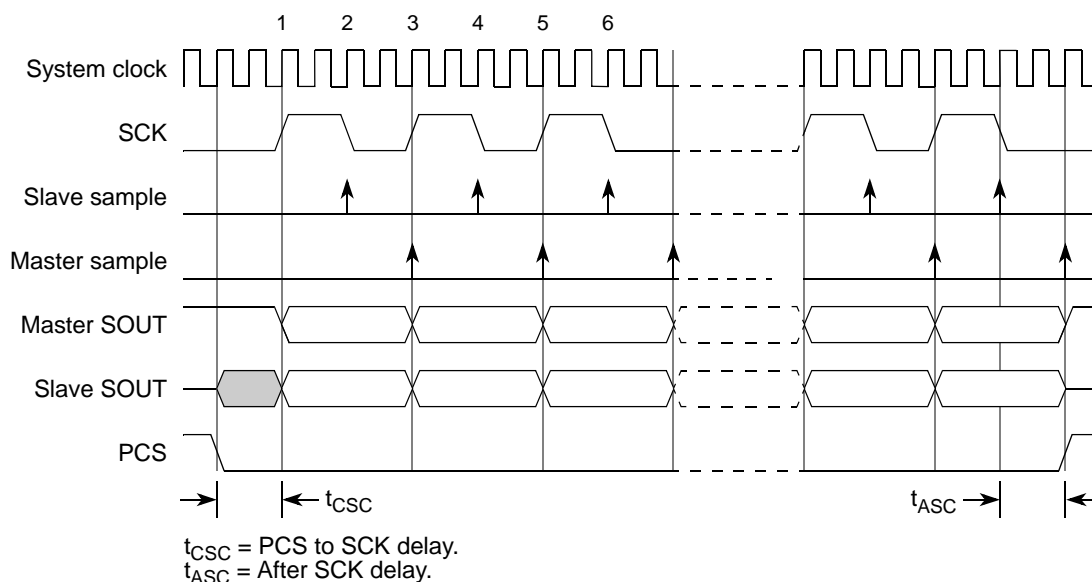

Figure 19-35. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{SCK} = f_{Sys} / 4$)

19.4.7.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The continuous selection format provides the flexibility to handle both cases. The continuous selection format is enabled for the SPI configuration by setting the CONT bit in the SPI command. Continuous selection is enabled for the DSI configuration by setting the DCONT bit in the DSPIx_DSICR. The behavior of the PCS signals in the two configurations is identical so only the SPI configuration is described.

When the CONT bit = 0, the DSPI drives the asserted chip select signals to their idle states in between frames. The idle states of the chip select signals are selected by the PCSIS field in the DSPIx_MCR.

Figure 19-36 shows the timing diagram for two four-bit transfers with $CPHA = 1$ and $CONT = 0$.

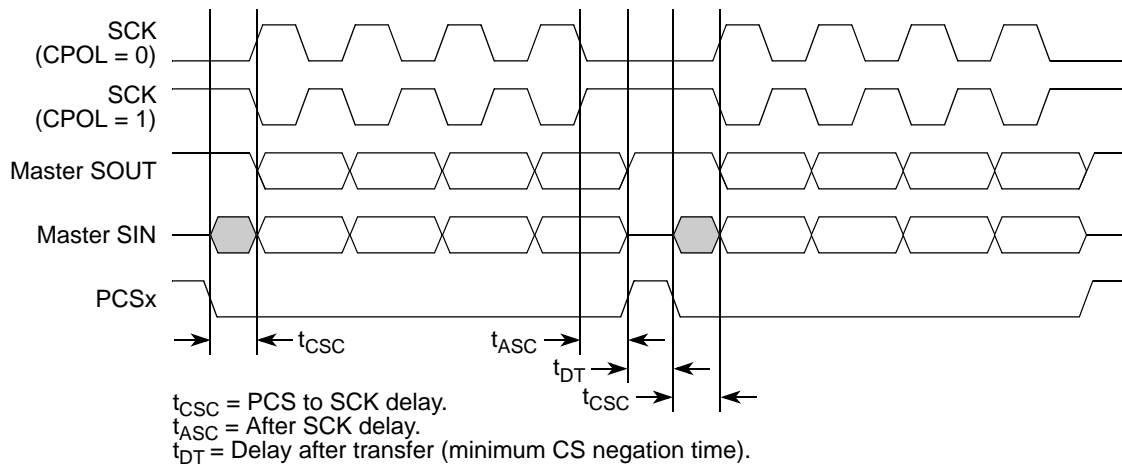

Figure 19-36. Example of Non-Continuous Format ($CPHA = 1$, $CONT = 0$)

When the $CONT = 1$ and the PCS signal for the next transfer is the same as for the current transfer, the PCS signal remains asserted for the duration of the two transfers. The delay between transfers (t_{DT}) is not inserted between the transfers.

Figure 19-37 shows the timing diagram for two 4-bit transfers with $CPHA = 1$ and $CONT = 1$.

Figure 19-37. Example of Continuous Transfer ($CPHA = 1$, $CONT = 1$)

In Figure 19-37, the period length at the start of the next transfer is the sum of t_{ASC} and t_{CSC} ; i.e., it does not include a half-clock period. The default settings for these provide a total of four system clocks. In many situations, t_{ASC} and t_{CSC} must be increased if a full half-clock period is required.

Switching CTARs between frames while using continuous selection can cause errors in the transfer. The PCS signal must be negated before CTAR is switched.

When the $CONT$ bit = 1 and the PCS signals for the next transfer are different from the present transfer, the PCS signals behave as if the $CONT$ bit was not set.

19.4.7.6 Clock Polarity Switching between DSPI Transfers

If it is desired to switch polarity between non-continuous DSPI frames, the edge generated by the change in the idle state of the clock occurs one system clock before the assertion of the chip select for the next frame.

Refer to [Section 19.3.2.3, “DSPI Clock and Transfer Attributes Registers 0–7 \(DSPIx_CTARn\).”](#)

In [Figure 19-38](#), time ‘A’ shows the one clock interval. Time ‘B’ is user programmable from a minimum of two system clocks.

Figure 19-38. Polarity Switching between Frames

19.4.8 Continuous Serial Communications Clock

The DSPI provides the option of generating a continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the DSPIx_MCR. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA = 1. Setting CPHA = 0 is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for modified transfer format.

Clock and transfer attributes for the continuous SCK mode are set according to the following rules:

- When the DSPI is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the DSPI is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.
- When the DSPI is in CSI configuration, the CTAR selected by the DSICTAS field is used initially. At the start of an SPI frame transfer, the CTAR specified by the CTAS value for the frame is used. At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the continuous SCK mode is terminated.

The device is designed to use the same baud rate for all transfers made while using the continuous SCK. Switching clock polarity between frames while using continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the DSPI is put into module disable mode.

Enabling continuous SCK disables the PCS to SCK delay and the After SCK delay. The delay after transfer is fixed at one SCK cycle. [Figure 19-39](#) shows timing diagram for continuous SCK format with continuous selection disabled.

Figure 19-39. Continuous SCK Timing Diagram (CONT= 0)

If the CONT bit in the TX FIFO entry is set or the DCONT in the DSPIx_DSICR is set, PCS remains asserted between the transfers when the PCS signal for the next transfer is the same as for the current transfer. [Figure 19-40](#) shows timing diagram for continuous SCK format with continuous selection enabled.

Figure 19-40. Continuous SCK Timing Diagram (CONT=1)

19.4.9 Interrupts/DMA Requests

The DSPI has five conditions that can generate interrupt requests only, and two conditions that can generate interrupt or DMA requests.

Table 19-29 lists the six conditions.

Table 19-29. Interrupt and DMA Request Conditions

Condition	Flag	Interrupt	DMA
End of transfer queue has been reached (EOQ)	EOQF	X	
TX FIFO is not full	TFFF	X	X
Current frame transfer is complete	TCF	X	
TX FIFO underflow has occurred	TFUF	X	
RX FIFO is not empty	RFDF	X	X
RX FIFO overflow occurred	RFOF	X	
A FIFO overrun occurred ¹	TFUF ORed with RFOF	X	

¹ The FIFO overrun condition is created by ORing the TFUF and RFOF flags together.

Each condition has a flag bit and a request enable bit. The flag bits are described in the [Section 19.3.2.4, “DSPI Status Register \(DSPIx_SR\)”](#) and the request enable bits are described in the [Section 19.3.2.5, “DSPI DMA / Interrupt Request Select and Enable Register \(DSPIx_RSER\).”](#) The TX FIFO fill flag (TFFF) and RX FIFO drain flag (RFDF) generate interrupt requests or DMA requests depending on the TFFF_DIRS and RFDF_DIRS bits in the DSPIx_RSER.

19.4.9.1 End of Queue Interrupt Request (EOQF)

The end of queue request indicates that the end of a transmit queue is reached. The end of queue request is generated when the EOQ bit in the executing SPI command is asserted and the EOQF_RE bit in the DSPIx_RSER is set. Refer to the EOQ bit description in [Section 19.3.2.4, “DSPI Status Register \(DSPIx_SR\).”](#) Refer to [Figure 19-32](#) and [Figure 19-33](#) that illustrate when EOQF is set.

19.4.9.2 Transmit FIFO Fill Interrupt or DMA Request (TFFF)

The transmit FIFO fill request indicates that the TX FIFO is not full. The transmit FIFO fill request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the DSPIx_RSER is set. The TFFF_DIRS bit in the DSPIx_RSER selects whether a DMA request or an interrupt request is generated.

19.4.9.3 Transfer Complete Interrupt Request (TCF)

The transfer complete request indicates the end of the transfer of a serial frame. The transfer complete request is generated at the end of each frame transfer when the TCF_RE bit is set in the DSPIx_RSER. Refer to the TCF bit description in [Section 19.3.2.4, “DSPI Status Register \(DSPIx_SR\).”](#) Refer to [Figure 19-32](#) and [Figure 19-33](#) that illustrate when TCF is set.

19.4.9.4 Transmit FIFO Underflow Interrupt Request (TFUF)

The transmit FIFO underflow request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for DSPI modules operating in slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of a DSPI operating in slave mode and SPI configuration is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the DSPLx_RSER is set, an interrupt request is generated.

19.4.9.5 Receive FIFO Drain Interrupt or DMA Request (RFDF)

The receive FIFO drain request indicates that the RX FIFO is not empty. The receive FIFO drain request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the DSPLx_RSER is set. The RFDF_DIRS bit in the DSPLx_RSER selects whether a DMA request or an interrupt request is generated.

19.4.9.6 Receive FIFO Overflow Interrupt Request (RFOF)

The receive FIFO overflow request indicates that an overflow condition in the RX FIFO has occurred. A receive FIFO overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the DSPLx_RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the DSPLx_MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is negated, the incoming data is ignored.

19.4.9.7 FIFO Overrun Request (TFUF) or (RFOF)

The FIFO overrun request indicates that at least one of the FIFOs in the DSPI has exceeded its capacity. The FIFO overrun request is generated by logically OR'ing together the RX FIFO overflow and TX FIFO underflow signals.

19.4.10 Power Saving Features

The DSPI supports two power-saving strategies:

- Module disable mode—clock gating of non-memory mapped logic
- Clock gating of slave interface signals and clock to memory-mapped logic

19.4.10.1 Module Disable Mode

Module disable mode is a module-specific mode that the DSPI can enter to save power. Host software can initiate the module disable mode by writing a 1 to the MDIS bit in the DSPLx_MCR. In module disable mode, the DSPI is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different affect when the DSPI is in the module disable mode. Reading the RX FIFO pop register does not change the state of the RX FIFO. Likewise, writing to the TX FIFO push register does not change the state of the TX FIFO. Clearing either of the FIFOs does not have any effect in the module disable mode. Changes to the DIS_TXF and DIS_RXF fields of the DSPLx_MCR does not have any affect in the module disable mode. In the module disable mode, all status bits and register flags

in the DSPI return the correct values when read, but writing to them has no effect. Writing to the DSPI_x_TCR during module disable mode does not have an effect. Interrupt and DMA request signals cannot be cleared while in the module disable mode.

19.4.10.2 Slave Interface Signal Gating

The DSPI module enable signal is used to gate slave interface signals such as address, byte enable, read/write and data. This prevents toggling slave interface signals from consuming power unless the DSPI is accessed.

19.5 Initialization and Application Information

19.5.1 How to Change Queues

DSPI queues are not part of the DSPI module, but the DSPI includes features in support of queue management. Queues are primarily supported in SPI configuration. This section presents an example of how to change queues for the DSPI.

1. The last command word from a queue is executed. The EOQ bit in the command word is set to indicate to the DSPI that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the DSPI_x_SR is set.
3. The setting of the EOQF flag disables both serial transmission, and serial reception of data, putting the DSPI in the STOPPED state. The TXRXS bit is negated to indicate the STOPPED state.
4. The eDMA continues to fill TX FIFO until it is full or step 5 occurs.
5. Disable DSPI DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the eDMA controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in DSPI_x_SR or by checking RFDF in the DSPI_x_SR after each read operation of the DSPI_x_POPR.
7. Modify DMA descriptor of TX and RX channels for “new” queues.
8. Flush TX FIFO by writing a 1 to the CLR_TXF bit in the DSPI_x_MCR register and flush the RX FIFO by writing a 1 to the CLR_RXF bit in the DSPI_x_MCR register.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the DSPI_x_TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the DSPI TX FIFO, and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

19.5.2 Baud Rate Settings

Table 19-30 shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the DSPIx_CTARs. The values are calculated at a 100 MHz system frequency.

Table 19-30. Baud Rate Values

		Baud Rate Divider Prescaler Values (DSPI_CTAR[PBR])			
		2	3	5	7
Baud Rate Scaler Values (DSPI_CTAR[BR])	2	25.0 MHz	16.7 MHz	10.0 MHz	7.14 MHz
	4	12.5 MHz	8.33 MHz	5.00 MHz	3.57 MHz
	6	8.33 MHz	5.56 MHz	3.33 MHz	2.38 MHz
	8	6.25 MHz	4.17 MHz	2.50 MHz	1.79 MHz
	16	3.12 MHz	2.08 MHz	1.25 MHz	893 kHz
	32	1.56 MHz	1.04 MHz	625 kHz	446 kHz
	64	781 kHz	521 kHz	312 kHz	223 kHz
	128	391 kHz	260 kHz	156 kHz	112 kHz
	256	195 kHz	130 kHz	78.1 kHz	55.8 kHz
	512	97.7 kHz	65.1 kHz	39.1 kHz	27.9 kHz
	1024	48.8 kHz	32.6 kHz	19.5 kHz	14.0 kHz
	2048	24.4 kHz	16.3 kHz	9.77 kHz	6.98 kHz
	4096	12.2 kHz	8.14 kHz	4.88 kHz	3.49 kHz
	8192	6.10 kHz	4.07 kHz	2.44 kHz	1.74 kHz
	16384	3.05 kHz	2.04 kHz	1.22 kHz	872 Hz
32768	1.53 kHz	1.02 kHz	610 Hz	436 Hz	

19.5.3 Delay Settings

Table 19-31 shows the values for the delay after transfer (t_{DT}) and CS to SCK delay (t_{CSC}) that can be generated based on the prescaler values and the scaler values set in the DSPIx_CTARs. The values calculated assume a 100 MHz system frequency.

Table 19-31. Delay Values

		Delay Prescaler Values (DSPI_CTAR[PBR])			
		1	3	5	7
Delay Scaler Values (DSPI_CTAR[DT])	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 μ s
	32	320.0 ns	960.0 ns	1.6 μ s	2.2 μ s
	64	640.0 ns	1.9 μ s	3.2 μ s	4.5 μ s
	128	1.3 μ s	3.8 μ s	6.4 μ s	9.0 μ s
	256	2.6 μ s	7.7 μ s	12.8 μ s	17.9 μ s
	512	5.1 μ s	15.4 μ s	25.6 μ s	35.8 μ s
	1024	10.2 μ s	30.7 μ s	51.2 μ s	71.7 μ s
	2048	20.5 μ s	61.4 μ s	102.4 μ s	143.4 μ s
	4096	41.0 μ s	122.9 μ s	204.8 μ s	286.7 μ s
	8192	81.9 μ s	245.8 μ s	409.6 μ s	573.4 μ s
	16384	163.8 μ s	491.5 μ s	819.2 μ s	1.1 ms
	32768	327.7 μ s	983.0 μ s	1.6 ms	2.3 ms
65536	655.4 μ s	2.0 ms	3.3 ms	4.6 ms	

19.5.4 MPC5xx QSPI Compatibility with the DSPI

Table 19-32 shows the translation of commands written to the TX FIFO command halfword with commands written to the command RAM of the MPC5xx family QSPI. The table illustrates how to configure the DSPIx_CTARs to match the default cases for the possible combinations of the MPC5xx family control bits in its command RAM. The defaults for the MPC5xx family are based on a system clock of 40 MHz.

The following delay variables generate the same delay, or as close as possible, from the DSPI 100 MHz system clock that an MPC5xx family part generates from a 40 MHz system clock. For other system clock frequencies, you can recompute the values using the information presented in [Section 19.5.3, “Delay Settings.”](#)

For BITSE = 0 --> 8 bits per transfer

For DT = 0 --> 0.425 μ s delay: for this value, the closest value in the DSPI is 0.480 μ s

For DSCK = 0 --> 0.5 of the SCK period: for this value, the value for the DSPI is 20 ns

Table 19-32. MPC5xx QSPI Compatibility with the DSPI

MPC5xx Family Control Bits DSPI Corresponding Control Bits						Corresponding DSPIx_CTAR Register Configuration					
BITSE	CTAS[0]	DT	CTAS[1]	DSCK	CTAS[2]	DSPIx_CTARx	FMSZ	PDT	DT	PCSSCK	CSSCK
0		0		0		0	0111	10	0011	00	0000

¹ Selected by user

19.5.5 Calculation of FIFO Pointer Addresses

The user has complete visibility of the TX and RX FIFO contents through the FIFO registers, and valid entries can be identified through a memory mapped pointer and a memory mapped counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the transmit next pointer (TXNXTPTR). For the RX FIFO the first-in pointer is the pop next pointer (POPNXTPTR).

Refer to [Section 19.4.3.4, “Transmit First In First Out \(TX FIFO\) Buffering Mechanism,”](#) and [Section 19.4.3.5, “Receive First In First Out \(RX FIFO\) Buffering Mechanism,”](#) for details on the FIFO operation. The TX FIFO is chosen for the illustration, but the concepts carry over to the RX FIFO.

Figure 19-41 illustrates the concept of first-in and last-in FIFO entries along with the FIFO counter.

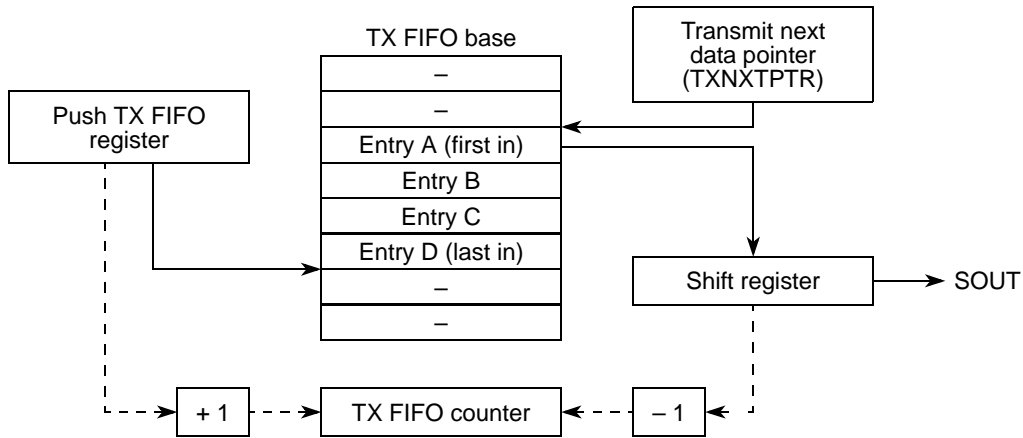

Figure 19-41. TX FIFO Pointers and Counter

19.5.5.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in entry address} = \text{TXFIFO base} + 4 (\text{TXNXPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-in entry address} = \text{TXFIFO base} + 4 \times [(\text{TXCTR} + \text{TXNXPTR} - 1) \text{ modulo TXFIFO depth}]$$

where:

TXFIFO base = base address of transmit FIFO

TXCTR = transmit FIFO counter

TXNXPTR = transmit next pointer

TX FIFO depth = transmit FIFO depth, implementation specific

19.5.5.2 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in entry address} = \text{RXFIFO base} + 4 \times (\text{POPXPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-in entry address} = \text{RXFIFO base} + 4 \times [(\text{RXCTR} + \text{POPXPTR} - 1) \text{ modulo RXFIFO depth}]$$

where:

RXFIFO base = base address of receive FIFO

RXCTR = receive FIFO counter

POPXPTR = pop next pointer

RX FIFO depth = receive FIFO depth, implementation specific

19.6 Document Revision History

Table 19-33. Changes Between MPC5565RM Revisions 0.1 and 1

<p>Added this bullet to the features list:</p> <ul style="list-style-type: none"> • “Supports all functional modes from QSPI subblock of QSMCM (MPC500 family)”
<p>Made this change to the first paragraph of Section 19.1.4, “Modes of Operation”</p> <ul style="list-style-type: none"> • From: These modes can be divided into two categories; module-specific modes such as master, slave, and module disable modes, and an MCU-specific mode (debug mode). • To: These modes can be divided into two categories; module-specific modes such as master, slave, and module disable modes, and a second category that is an MCU-specific mode: debug mode
<p>Changed the note in the DSPI_PUSH register:</p> <ul style="list-style-type: none"> • From: “Only the TXDATA field is used for slaves.” • To: “TXDATA is used in master and slave modes.”
<p>Section 19.5.5.2, “Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO,” changed</p> <ul style="list-style-type: none"> • From: “First-in entry address = TX FIFO base + 4 x (POPNEXTPTR)” • To: “First-in entry address = RX FIFO base + 4 x (POPNEXTPTR)”

Chapter 20

Enhanced Serial Communication Interface (eSCI)

20.1 Introduction

This section gives an overview of the enhanced serial communication interface (eSCI) module, and presents a block diagram, its features and operating modes.

20.1.1 Block Diagram

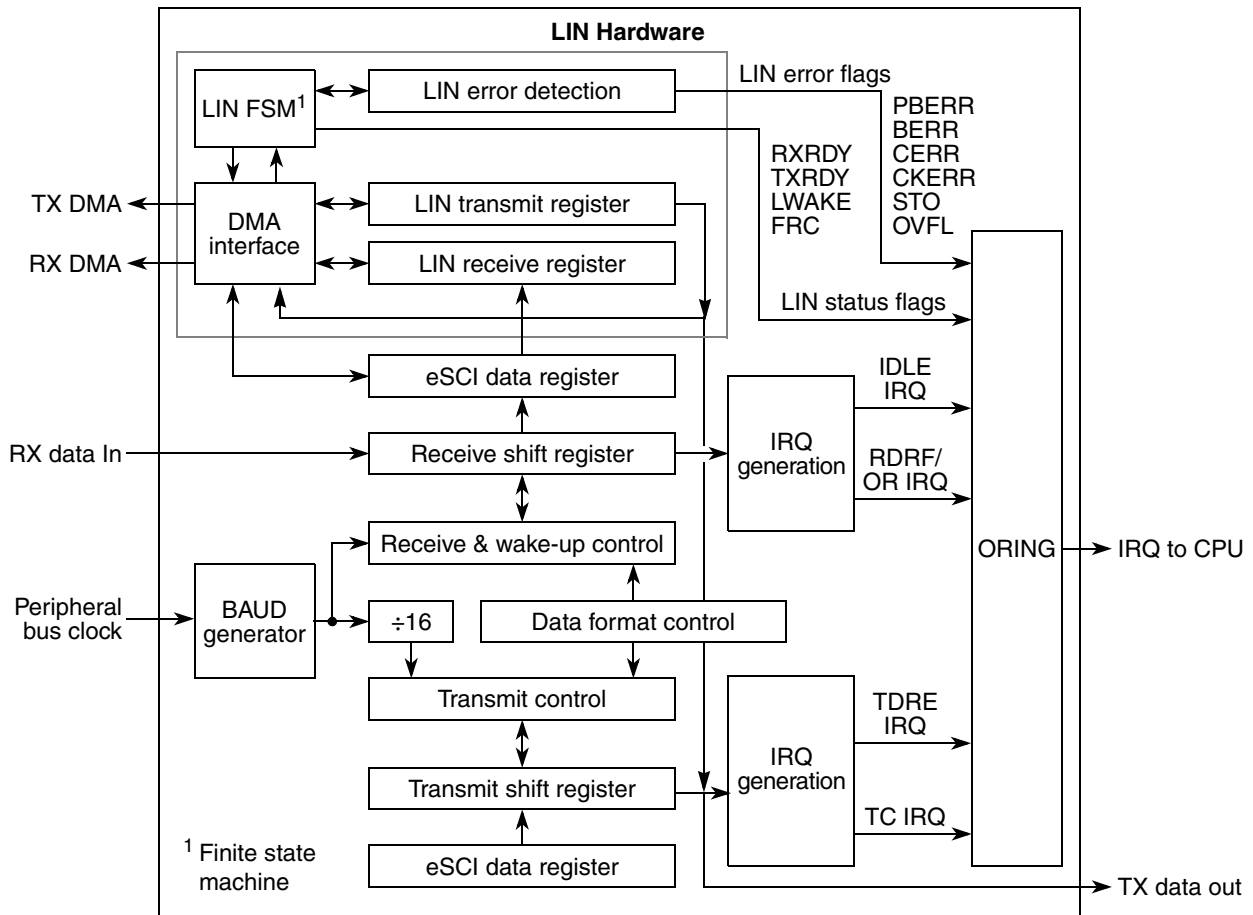

Figure 20-1. eSCI Block Diagram

20.1.2 Overview

The eSCI allows asynchronous serial communications with peripheral devices and other CPUs. The eSCI features allow it to operate as a LIN bus master, complying with the LIN 2.0 specification.

Each of the eSCI modules can be independently disabled by writing to the module disable (MDIS) bit in the module control register 2 (ESCIx_CR2). Disabling the module turns off the clock to the module, although the core can access some of eSCI registers via the slave bus. When the eSCI module is not used in the application, set the MDIS bit.

20.1.3 Features

The eSCI includes these features:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- Configurable baud rate
- Programmable 8- or 9-bit data format
- LIN master node support
- Configurable CRC detection for LIN
- Separately enabled transmitter and receiver
- Programmable transmitter output parity
- Two receiver wake-up methods:
 - Idle line wake-up
 - Address mark wake-up
- Interrupt-driven operation
- Receiver framing error detection
- Hardware parity checking
- 1/16 bit-time noise detection
- Two-channel DMA interface

20.1.4 Modes of Operation

The eSCI functions the same in normal, special, and emulation modes. It has a low-power module disable mode.

20.2 External Signal Description

This section provides a description of all eSCI external to the MCU.

Each eSCI module has two I/O signals connected to the external MCU pins. These signals are summarized in [Table 20-1](#) and described in more detail in the following sections.

Table 20-1. eSCI Signals

Signal Name ¹	I/O	Description
RXD _x	I	eSCI receive
TXD _x	O	eSCI transmit

¹ x indicates eSCI module A or B

20.2.1 Detailed Signal Description

20.2.1.1 eSCI Transmit (TXDA, TXDB)

These signals transmit data out for the eSCI.

20.2.1.2 eSCI Receive Pin (RXDA, RXDB)

These signals receive data input for the eSCI.

20.3 Memory Map and Register Definition

20.3.1 Overview

This section provides a detailed description of all memory and registers.

20.3.2 Module Memory Map

The memory map for the eSCI module is shown in [Table 20-2](#). The address offset is listed for each register. The total address for each register is the sum of the base address for the eSCI module (ESCI_x_base) and the address offset for each register. There are two eSCI modules on this device:

- eSCI A base address is 0xFFFFB_0000
- eSCI B base address is 0xFFFFB_4000

Table 20-2. Module Memory Map

Address	Register Name	Register Description	Bits
Base 0xFFFFB_0000 (A) 0xFFFFB_4000 (B)	ESCIx_CR1	eSCI control register 1	32
Base + 0x0004	ESCIx_CR2	eSCI control register 2	16
Base + 0x0006	ESCIx_DR	eSCI data register	16
Base + 0x0008	ESCIx_SR	eSCI status register	32
Base + 0x000C	ESCIx_LCR	LIN control register	32
Base + 0x0010	ESCIx_LTR	LIN transmit register	32
Base + 0x0014	ESCIx_LRR	LIN receive register	32
Base + 0x0018	ESCIx_LPR	LIN cyclic redundancy check polynomial register	32

20.3.3 Register Descriptions

This section contains the register descriptions in address order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field functions follow the register diagrams, in bit order.

20.3.3.1 eSCI Control Register 1 (ESCIx_CR1)

Address: Base + 0x0000

Access: R/W

Figure 20-2. eSCI Control Register 1 (ESCIx_CR1)

Table 20-3. ESCI_x_CR1 Field Descriptions

Field	Description												
0–2	Reserved.												
3–15 SBR _n	SCI baud rate. Used by the counter to determine the baud rate of the eSCI. The formula for calculating the baud rate is: $\text{SCI baud rate} = \frac{\text{eSCI system clock}}{16 \times \text{BR}}$ where BR is the content of the eSCI control register 1 (ESCI _x _CR1), bits SBR0–SBR12. SBR0–SBR12 can contain a value from 1 to 8191. Refer to the ESCI _x _LCR[WU] bit description on page 20-12.												
16 LOOPS	Loop select. Enables loop operation. In loop operation, the RXD pin is disconnected from the eSCI and the transmitter output is internally connected to the receiver input. Both the transmitter and the receiver must be enabled to use the loop function. 0 Normal operation enabled, loop operation disabled 1 Loop operation enabled Note: The receiver input is determined by the RSRC bit.												
17	Reserved.												
18 RSRC	Receiver source. When LOOPS = 1, the RSRC bit determines the source for the receiver shift register input. 0 Receiver input internally connected to transmitter output 1 Receiver input connected externally to transmitter The table below shows how LOOPS and RSRC determine the loop function of the eSCI. <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>LOOPS</th> <th>RSRC</th> <th>Function</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>–</td> <td>Normal operation</td> </tr> <tr> <td>1</td> <td>0</td> <td>Loop mode with RXD input internally connected to TXD output</td> </tr> <tr> <td>1</td> <td>1</td> <td>Single-wire mode with RXD input connected to TXD</td> </tr> </tbody> </table>	LOOPS	RSRC	Function	0	–	Normal operation	1	0	Loop mode with RXD input internally connected to TXD output	1	1	Single-wire mode with RXD input connected to TXD
LOOPS	RSRC	Function											
0	–	Normal operation											
1	0	Loop mode with RXD input internally connected to TXD output											
1	1	Single-wire mode with RXD input connected to TXD											
19 M	Data format mode. Determines whether data characters are 8 or 9 bits long. 0 1 start bit, 8 data bits, 1 stop bit 1 1 start bit, 9 data bits, 1 stop bit												
20 WAKE	Wake-up condition. Determines which condition wakes up the eSCI: a logic 1 (address mark) in the most significant bit (MSB) position of a received data character or an idle condition on the RXD. 0 Idle line wake-up 1 Address mark wake-up Note: This is not a wake-up from a power-save mode; this function applies to the receiver standby mode only.												
21 ILT	Idle line type. Determines when the receiver starts counting logic 1s as idle character bits. The counting begins either after the start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. 0 Idle character bit count begins after start bit 1 Idle character bit count begins after stop bit												
22 PE	Parity enable. Enables the parity function. When enabled, the parity function inserts a parity bit in the most significant bit position of the transmitted word. During reception, the received parity bit is verified in the most significant bit position. The received parity bit is not masked out. 0 Parity function disabled 1 Parity function enabled												

Table 20-3. ESCIx_CR1 Field Descriptions (continued)

Field	Description
23 PT	Parity type. Determines whether the eSCI generates and checks for even parity or odd parity. With even parity, an even number of 1s clears the parity bit and an odd number of 1s sets the parity bit. With odd parity, an odd number of 1s clears the parity bit and an even number of 1s sets the parity bit. 0 Even parity 1 Odd parity
24 TIE	Transmitter interrupt enable. Enables the transmit data register empty flag ESCIx_SR[TDRE] to generate interrupt requests. The interrupt is suppressed in TX DMA mode. 0 TDRE interrupt requests disabled 1 TDRE interrupt requests enabled
25 TCIE	Transmission complete interrupt enable. Enables the transmission complete flag ESCIx_SR[TC] to generate interrupt requests. The interrupt is suppressed in TX DMA mode. 0 TC interrupt requests disabled 1 TC interrupt requests enabled
26 RIE	Receiver full interrupt enable. Enables the receive data register full flag ESCIx_SR[RDRF] and the overrun flag ESCIx_SR[OR] to generate interrupt requests. The interrupt is suppressed in RX DMA mode. 0 RDRF and OR interrupt requests disabled 1 RDRF and OR interrupt requests enabled
27 ILIE	Idle line interrupt enable. Enables the idle line flag ESCIx_SR[IDLE] to generate interrupt requests. 0 IDLE interrupt requests disabled 1 IDLE interrupt requests enabled
28 TE	Transmitter enable. Enables the eSCI transmitter and configures the TXD pin as being controlled by the eSCI. The TE bit can be used to queue an idle preamble. 0 Transmitter disabled 1 Transmitter enabled
29 RE	Receiver enable. Enables the eSCI receiver. 0 Receiver disabled 1 Receiver enabled
30 RWU	Receiver wake-up. Standby state. 0 Normal operation. 1 RWU enables the wake-up function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU.
31 SBK	Send break. Toggling SBK sends one break character (Refer to the description of ESCIx_CR2[BRK13] for break character length). Toggling implies clearing the SBK bit before the break character has finished transmitting. As long as SBK is set, the transmitter continues to send complete break characters. 0 No break characters 1 Transmit break characters

NOTES

After a reset, the baud rate generator is disabled until the TE bit or the RE bit is initialized (set for the first time).

The baud rate generator is disabled when $SBR0-SBR12 = 0x0000$.

The baud rate is usually written using a single write. If using 8-bit writes, writing to $ESCIx_CR1[0-7]$ has no effect until $ESCIx_CR1[8-15]$ is written, since $ESCIx_CR1[0-7]$ is temporarily buffered until $ESCIx_CR1[8-15]$ is written.

When parity is enabled, the RX Data parity bit is in the data register.

20.3.3.2 eSCI Control Register 2 (ESCIx_CR2)

NOTE

DMA requests are negated when in module disable mode.

Address: Base + 0x0004

Figure 20-3. eSCI Control Register 2 (ESCIx_CR2)

Table 20-4. ESCIx_CR2 Field Description

Field	Description
0 MDIS	Module disable. By default the module is enabled, but can be disabled by writing a 1 to this bit. DMA requests are negated if the device is in module disable mode. 0 Module enabled 1 Module disabled
1 FBR	Fast bit error detection. Handles bit error detection on a per bit basis. If this is not enabled, bit errors are detected on a byte basis.
2 BSTP	Bit error/physical bus error stop. Causes DMA TX requests to be suppressed, as long as the bit error and physical bus error flags are not cleared. This stops further DMA writes, which would otherwise cause data bytes to be interpreted as LIN header information.
3 IEBERR	Enable bit error interrupt. Generates an interrupt, when a LIN bit error is detected. For a list of interrupt enables and flags, Refer to Table 20-21 .
4 RXDMA	Activate RX DMA channel. If this bit is enabled and the eSCI has received data, it raises a DMA RX request.
5 TXDMA	Activate TX DMA channel. Whenever the eSCI is able to transmit data, it raises a DMA TX request.

Table 20-4. ESCIx_CR2 Field Description (continued)

Field	Description													
6 BRK13	<p>Break transmit character length. Determines whether the transmit break character is 10/11 or 13/14 bits long. The detection of a framing error is not affected by this bit.</p> <p style="text-align: center;">Break Length:</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <tr> <td colspan="2" rowspan="2"></td> <td colspan="2" style="text-align: center;">ESCIx_CR1[M]</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> </tr> <tr> <td rowspan="2" style="text-align: center;">BRK13</td> <td style="text-align: center;">0</td> <td style="text-align: center;">10</td> <td style="text-align: center;">11</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">13</td> <td style="text-align: center;">14</td> </tr> </table> <p>0 Break Character is 10 or 11 bits long 1 Break character is 13 or 14 bits long Note: LIN 2.0 now requires that a break character is always 13 bits long, always set this bit to 1. The eSCI works with BRK13=0, but it violates LIN 2.0.</p>			ESCIx_CR1[M]		0	1	BRK13	0	10	11	1	13	14
				ESCIx_CR1[M]										
		0	1											
BRK13	0	10	11											
	1	13	14											
7	Reserved. This bit is readable/writable, but has no effect on the operation of the eSCI module.													
8 BESM13	<p>Bit error sample mode, bit 13. Determines when to sample the incoming bit to detect a bit error. (This is only relevant when FBR is set.)</p> <p>0 Sample at RT clock 9 1 Sample at RT clock 13 (Refer to Section 20.4.5.3, "Data Sampling")</p>													
9 SBSTP	<p>SCI bit error stop. Stops the SCI when a bit error is asserted. This allows to stop driving the LIN bus quickly after a bit error has been detected.</p> <p>0 Byte is completely transmitted 1 Byte is partially transmitted</p>													
10–11	Reserved.													
12 ORIE	Overrun error interrupt enable. Generates an interrupt, when a frame error is detected. For a list of interrupt enables and flags, Refer to Table 20-21 .													
13 NFIE	Noise flag interrupt enable. Generates an interrupt, when noise flag is set. For a list of interrupt enables and flags, Refer to Table 20-21 .													
14 FEIE	Frame error interrupt enable. Generates an interrupt, when a frame error is detected. For a list of interrupt enables and flags, Refer to Table 20-21 .													
15 PFIE	Parity flag interrupt enable. Generates an interrupt, when parity flag is set. For a list of interrupt enables and flags, Refer to Table 20-21 .													

20.3.3.3 eSCI Data Register (ESCIx_DR)

Address: Base + 0x0006

Access: R/W

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	R8	T8	0	0	0	0	0	0	R7	R6	R5	R4	R3	R2	R1	R0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 20-4. eSCI Data Register (ESCIx_DR)

Table 20-5. ESCI_x_DR Field Description

Field	Description
0 R8	Received bit 8. R8 is the ninth data bit received when the eSCI is configured for 9-bit data format (M = 1).
1 T8	Transmit bit 8. T8 is the ninth data bit transmitted when the eSCI is configured for 9-bit data format (M = 1). Note: If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten. The same value is transmitted until T8 is rewritten.
2–7	Reserved.
8–15 R7–R0 T7–T0	Received bits/transmit bits 7–0 for 9-bit or 8-bit formats. Bits 7–0 from SCI communication can be read from ESCI _x _DR[8–15] (provided that SCI communication was successful). Writing to ESCI _x _DR [8–15] provides bits 7–0 for SCI transmission.

NOTES

In 8-bit data format, only bits 8–15 of ESCI_x_DR need to be accessed.

When transmitting in 9-bit data format and using 8-bit write instructions, write first to ESCI_x_DR[0–7], then ESCI_x_DR[8–15]. For 9-bit transmissions, a single write can also be used.

Do not use ESCI_x_DR in LIN mode, writes to this register are blocked in LIN mode.

Even if parity generation/checking is enabled via ESCI_x_CR[PE], the parity bit is not masked out.

20.3.3.4 eSCI Status Register (ESCI_x_SR)

The ESCI_x_SR indicates the current status. The status flags can be polled, and some can also be used to generate interrupts. All bits in ESCI_x_SR except for RAF are cleared by writing 1 to them.

Address: Base + 0x0008

Access: R/W1c

Figure 20-5. eSCI Status Register (ESCI_x_SR)

Table 20-6. ESCIx_SR Field Descriptions

Field	Description
0 TDRE	<p>Transmit data register empty flag. TDRE is set when the transmit shift register receives a byte from the eSCI data register. When TDRE is 1, the data register (ESCIx_DR) is empty and can receive a new value to transmit. Clear TDRE by writing 1 to it.</p> <p>0 eSCI has not transferred data to the transmit shift register since the last time software cleared TDRE 1 Byte transferred to transmit shift register; transmit data register empty</p>
1 TC	<p>Transmit complete flag. TC is set low when there is a transmission in progress or when a preamble or break character is loaded. TC is set high when the TDRE flag is set and no data, preamble, or break character is being transmitted. When TC is set, the TXD out signal becomes idle (logic 1).</p> <p>After the device is switched on (by clearing the MDIS bit, Refer to Section 20.3.3.2, “eSCI Control Register 2 (ESCIx_CR2)”, a preamble is transmitted; if no byte is written to the SCI data register then the completion of the preamble can be monitored using the TC flag. Clear TC by writing 1 to it.</p> <p>0 Transmission in progress 1 No transmission in progress. Indicates that TXD out is idle.</p>
2 RDRF	<p>Receive data register full flag. RDRF is set when the data in the receive shift register transfers to the eSCI data register. Clear RDRF by writing 1 to it.</p> <p>0 eSCI has not transferred data to the receive data register since last time software cleared RDRF 1 Received data available in eSCI data register</p>
3 IDLE	<p>Idle line flag. IDLE is set when 10 consecutive logic 1s (if M = 0) or 11 consecutive logic 1s (if M = 1) appear on the receiver input. After the IDLE flag is cleared, a valid frame must again set the RDRF flag before an idle condition can set the IDLE flag. Clear IDLE by writing 1 to it.</p> <p>0 Receiver input is either active now or has never become active since the IDLE flag was last cleared 1 Receiver input has become idle</p> <p>Note: When the receiver wake-up bit (RWU) is set, an idle line condition does not set the IDLE flag.</p>
4 OR	<p>Overrun flag. OR is set when software fails to read the eSCI data register before the receive shift register receives the next frame. The OR bit is set immediately after the stop bit has been completely received for the second frame. The data in the shift register is lost, but the data already in the eSCI data registers is not affected. Clear OR by writing 1 to it.</p> <p>0 No overrun 1 Overrun</p>
5 NF	<p>Noise flag. NF is set when the eSCI detects noise on the receiver input. NF bit is set during the same cycle as the RDRF flag but does not get set in the case of an overrun. Clear NF by writing 1 to it.</p> <p>0 No noise 1 Noise</p>
6 FE	<p>Framing error flag. FE is set when a logic 0 is accepted as the stop bit. FE bit is set during the same cycle as the RDRF flag but does not get set in the case of an overrun. Clear FE by writing 1 to it.</p> <p>0 No framing error 1 Framing error</p>
7 PF	<p>Parity error flag. PF is set when the parity enable bit, PE, is set and the parity of the received data does not match its parity bit. Clear PE by writing 1 to it.</p> <p>0 No parity error 1 Parity error</p>
8–10	Reserved, Must be 0.

Table 20-6. ESCIx_SR Field Descriptions (continued)

Field	Description
11 BERR	Bit error. Indicates a bit on the bus did not match the transmitted bit. If FBR = 0, checking happens after a complete byte has been transmitted and received again. If FBR = 1, checking happens bit by bit. This bit is only used for LIN mode. BERR is also set if an unrequested byte is received (i.e. a byte that is not part of an RX frame) that is not recognized as a wake-up flag. (Because the data on the RX line does not match the idle state that was assigned to the TX line.) Clear BERR by writing 1 to it. A bit error causes the LIN finite state machine (FSM) to reset unless ESCIx_LCR[LDBG] is set.
12–14	Reserved.
15 RAF	Receiver active flag. RAF is set when the receiver detects a logic 0 during the RT1 time period of the start bit search. RAF is cleared when the receiver detects an idle character. 0 No reception in progress. 1 Reception in progress.
16 RXRDY	The eSCI has received LIN data. This bit is set when the ESCIx_LCR receives a byte. Clear RXRDY by writing it with 1.
17 TXRDY	The LIN FSM can accept another write to ESCIx_LTR. This bit is set when the ESCIx_LTR register becomes free. Clear TXRDY by writing it with 1.
18 LWAKE	Received LIN wake-up signal. A LIN slave has sent a wake-up signal on the bus. When this signal is detected, the LIN FSM resets. If the setup of a frame had already started, it therefore must be repeated. LWAKE is set if ESCI receives a LIN 2.0 wake-up signal (in which the baud rate is lower than 32K baud). Refer to the WU bit.
19 STO	Slave time out. Represents a NO_RESPONSE_ERROR. This is set if a slave does not complete a frame within the specified maximum frame length. For LIN 1.3 the following formula is used: $TFRAME_MAX = (10 \times NDATA + 44) \times 1.4$
20 PBERR	Physical bus error. No valid message can be generated on the bus. This is set if, after the start of a byte transmission, the input remains unchanged for 31 cycles. This resets the LIN FSM.
21 CERR	CRC error. The CRC pattern received with an extended frame was not correct. 0 No error 1 CRC error
22 CKERR	Checksum error. Checksum error on a received frame.
23 FRC	Frame complete. LIN frame completely transmitted. All LIN data bytes received.
24–30	Reserved.
31 OVFL	ESCIx_LRR overflow. The LIN receive register has not been read before a new data byte, CRC, or checksum byte has been received from the LIN bus. Set when the condition is detected, and cleared by writing 1 to it.

20.3.3.5 LIN Control Register (ESCIx_LCR)

ESCIx_LCR can be written only when there are no ongoing transmissions.

Address: Base + 0x000C

Access: R/W

Figure 20-6. LIN Control Register (ESCIx_LCR)

Table 20-7. ESCI_x_LCR Field Descriptions

Field	Description															
0 LRES	LIN resynchronize. Causes the LIN protocol engine to return to start state. This happens automatically after bit errors, but software can force a return to start state manually via this bit. The bit first must be set then cleared, so that the protocol engine is operational again.															
1 WU	LIN bus wake-up. Generates a wake-up signal on the LIN bus. This must be set before a transmission, if the bus is in sleep mode. This bit auto-clears, so a read from this bit always returns 0. According to LIN 2.0, generating a valid wake-up character requires programming the SCI baud rate to a range of 32K baud down to 1.6K baud.															
2–3 WUD [0:1]	Wake-up delimiter time. Determines how long the LIN engine waits after generating a wake-up signal, before starting a new frame. The eSCI does not set ESCI _x _SR[TXRDY] before this time expires. In addition to this delimiter time, the CPU and the eSCI require some setup time to start a new transmission. Typically there is an additional bit time delay. The following table shows how WUD0 and WUD1 affect the delimiter time. <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>WUD0</th> <th>WUD1</th> <th>Bit Times</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>4</td> </tr> <tr> <td>0</td> <td>1</td> <td>8</td> </tr> <tr> <td>1</td> <td>0</td> <td>32</td> </tr> <tr> <td>1</td> <td>1</td> <td>64</td> </tr> </tbody> </table>	WUD0	WUD1	Bit Times	0	0	4	0	1	8	1	0	32	1	1	64
WUD0	WUD1	Bit Times														
0	0	4														
0	1	8														
1	0	32														
1	1	64														
4 LDBG	LIN debug mode. Prevents the LIN FSM from automatically resetting, after an exception (bit error, physical bus error, wake-up flag) has been received. This is for debug purposes only.															
5 DSF	Double stop flags. When a bit error is detected, an additional stop flag is added to the byte in which the error occurred.															
6 PRTY	Activating parity generation. Generate the two parity bits in the LIN header.															

Table 20-7. ESCIx_LCR Field Descriptions (continued)

Field	Description
7 LIN	LIN mode. Switch device into LIN mode. 0 LIN disabled 1 LIN enabled
8 RXIE	LIN RXREG ready interrupt enable. Generates an Interrupt when new data is available in the LIN RXREG. For a list of interrupt enables and flags, Refer to Table 20-21 .
9 TXIE	LIN TXREG ready interrupt enable. Generates an Interrupt when new data can be written to the LIN TXREG. For a list of interrupt enables and flags, Refer to Table 20-21 .
10 WUIE	RX wake-up interrupt enable. Generates an Interrupt when a wake-up flag from a LIN slave has been received. For a list of interrupt enables and flags, Refer to Table 20-21 .
11 STIE	Slave timeout error interrupt enable. Generates an Interrupt when the slave response is too slow. For a list of interrupt enables and flags, Refer to Table 20-21 .
12 PBIE	Physical bus error interrupt enable. Generates an Interrupt when no valid message can be generated on the bus. For a list of interrupt enables and flags, Refer to Table 20-21 .
13 CIE	CRC error interrupt enable. Generates an Interrupt when a CRC error on a received extended frame is detected. For a list of interrupt enables and flags, Refer to Table 20-21 .
14 CKIE	Checksum error interrupt enable. Generates an Interrupt on a detected checksum error. For a list of interrupt enables and flags, Refer to Table 20-21 .
15 FCIE	Frame complete interrupt enable. Generates an Interrupt after complete transmission of a TX frame, or after the last byte of an RX frame is received. (The complete frame includes all header, data, CRC and checksum bytes as applicable.) For a list of interrupt enables and flags, Refer to Table 20-21 .
16–22	Reserved.
23 OFIE	Overflow interrupt enable. Generates an Interrupt when a data byte in the ESCIx_LRR has not been read before the next data byte is received. For a list of interrupt enables and flags, Refer to Table 20-21 .
24–31	Reserved.

20.3.3.6 LIN Transmit Register (ESCIx_LTR)

ESCIx_LTR can be written to only when TXRDY is set. The first byte written to the register selects the transmit address, the second byte determines the frame length, the third and fourth byte set various frame options and determine the timeout counter. Header parity is automatically generated if the ESCIx_LCR[PRTY] bit is set. For TX frames, the fourth byte (bits T7–T0) is skipped, since the timeout function does not apply. All following bytes are data bytes for the frame. CRC and checksum bytes are automatically appended when the appropriate options are selected.

When a bit error is detected, an interrupt is set and the transmission aborted. The register can only be written again after the interrupt is cleared. Afterwards a new frame starts, and the first byte needs to contain a header again.

Additionally it is possible to flush the ESCIx_LTR by setting the ESCIx_LCR[LRES] bit.

NOTE

Not all values written to the ESCIx_LTR generate valid LIN frames. The values are determined according to the LIN specification.

1	0	4														
1	1	8														
8–31	Reserved.															

¹ The values 3C, 3D, 3E and 3F of the ID-field (ID0-5) indicate command and extended frames. Refer to LIN Specification Package Revision 2.0.

Table 20-9. ESCIx_LTR Second-Byte Field Description

Field	Description
0–7 L_n	Length bit n . Defines the length of the frame (0 to 255 data bytes). This information is needed by the LIN state machine to insert the checksum or CRC pattern as required. LIN 1.x slaves only accepts frames with 2, 4, or 8 data bytes.
8–31	Reserved.

Table 20-10. ESCIx_LTR Third-Byte Field Descriptions

Field	Description
0 HDCHK	Header checksum enable. Include the header fields into the mod 256 checksum of the standard frames.
1 CSUM	Checksum enable. Append a checksum byte to the end of a TX frame. Verify the checksum byte of an RX frame.
2 CRC	CRC enable. Append two CRC bytes to the end of a TX frame. Verify the two CRC bytes of an RX frame are correct. If both CSUM and CRC bits are set, the LIN FSM first appends the CRC bytes, then the checksum byte, and are processed in this order. If HDCHK is set, the CRC calculation includes the header and data bytes, otherwise, the CRC is performed on the data bytes only. CRC bytes are not part of the LIN standard; they are normal data bytes and belong to a higher-level protocol.
3 TX	Transmit direction. Indicates that the eSCI transmits a frame to a slave. Otherwise, an RX frame is assumed, and the eSCI only transmits the header. The data bytes are received from the slave. 0 RX frame 1 TX frame

Table 20-10. ESCIx_LTR Third-Byte Field Descriptions (continued)

Field	Description
4–7 T_n	Timeout bit n . Sets the counter to determine a NO_RESPONSE_ERROR, if the frame is a read access to a LIN slave. Following LIN standard rev 1.3, the value $(10 \times N_{DATA} + 45) \times 1.4$ is recommended. For transmissions, this counter has to be set to 0. The timeout bits 7–0 are not written on a TX frame. For TX frames, the fourth byte written to the LIN transmit register (ESCIx_LTR) is the first data byte, for RX frames it contains timeout bits 7–0. The time is specified in multiples of bit times. The timeout period starts with the transmission of the LIN break character.
8–31	Reserved.

Table 20-11. ESCIx_LTR Rx Frame Fourth Byte Field Description

Field	Description
0–7 T_n	Timeout bit n . Sets the counter to determine a NO_RESPONSE_ERROR, if the frame is a read access to a LIN slave. Follow the LIN standard rev 1.3, the value $(10 \times N_{DATA} + 45) \times 1.4$. For transmissions, this counter must be set to 0. The timeout bits 7–0 are not written on a TX frame. For TX frames, the fourth byte written to the LIN transmit register (ESCIx_LTR) is the first data byte. For RX frames, it contains timeout bits 7–0. The time is specified in multiples of bit times. The timeout period starts with the transmission of the LIN break character.
8–31	Reserved.

Figure 20-9. LIN Receive Register (ESCIx_LRR)

Table 20-13. ESCIx_LRR Field Descriptions

Field	Description
0–7 Dn	<p>Data bit <i>n</i>. Provides received data bytes from RX frames. Data is only valid when the ESCIx_SR[RXRDY] flag is set. CRC and checksum information are not available in the ESCIx_LRR unless they are treated as data. It is possible to treat CRC and checksum bytes as data by deactivating the CSUM respectively CRC control bits in the ESCIx_LTR; however, then CRC and CSUM checking has to be performed by software.</p> <p>Data bytes must be read from the ESCIx_LRR (by CPU or DMA) before any new bytes (including CRC or checksum) are received from the LIN bus otherwise the data byte is lost and OVFL is set.</p> <p>Note: The data must be collected and the LIN frame finished (including CRC and checksum if applicable) before a wake-up character can be sent.</p>
8–31	Reserved.

20.3.3.8 LIN CRC Polynomial Register (ESCIx_LPR)

ESCIx_LPRn can be written when there are no ongoing transmissions.

Address: Base + 0x0018

Access: R/W

Figure 20-10. LIN CRC Polynomial Register (ESCIx_LPR)

Table 20-14. ESCIx_LPR Field Description

Field	Description
0–15 Pn	Polynomial bit x^n . Bits P15–P0 are used to define the LIN polynomial - standard is $x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1$ (the polynomial used for the CAN protocol).
16–31	Reserved.

20.4 Functional Description

20.4.1 Overview

This section provides a complete functional description of the eSCI module, detailing the operation of the design from the end user perspective in a number of subsections.

Figure 20-11 shows the structure of the eSCI module. The eSCI allows full duplex, asynchronous, NRZ serial communication between the CPU and remote devices, including other CPUs. The eSCI transmitter and receiver operate independently, although they use the same baud rate generator. The CPU monitors the status of the eSCI, writes the data to be transmitted, and processes received data.

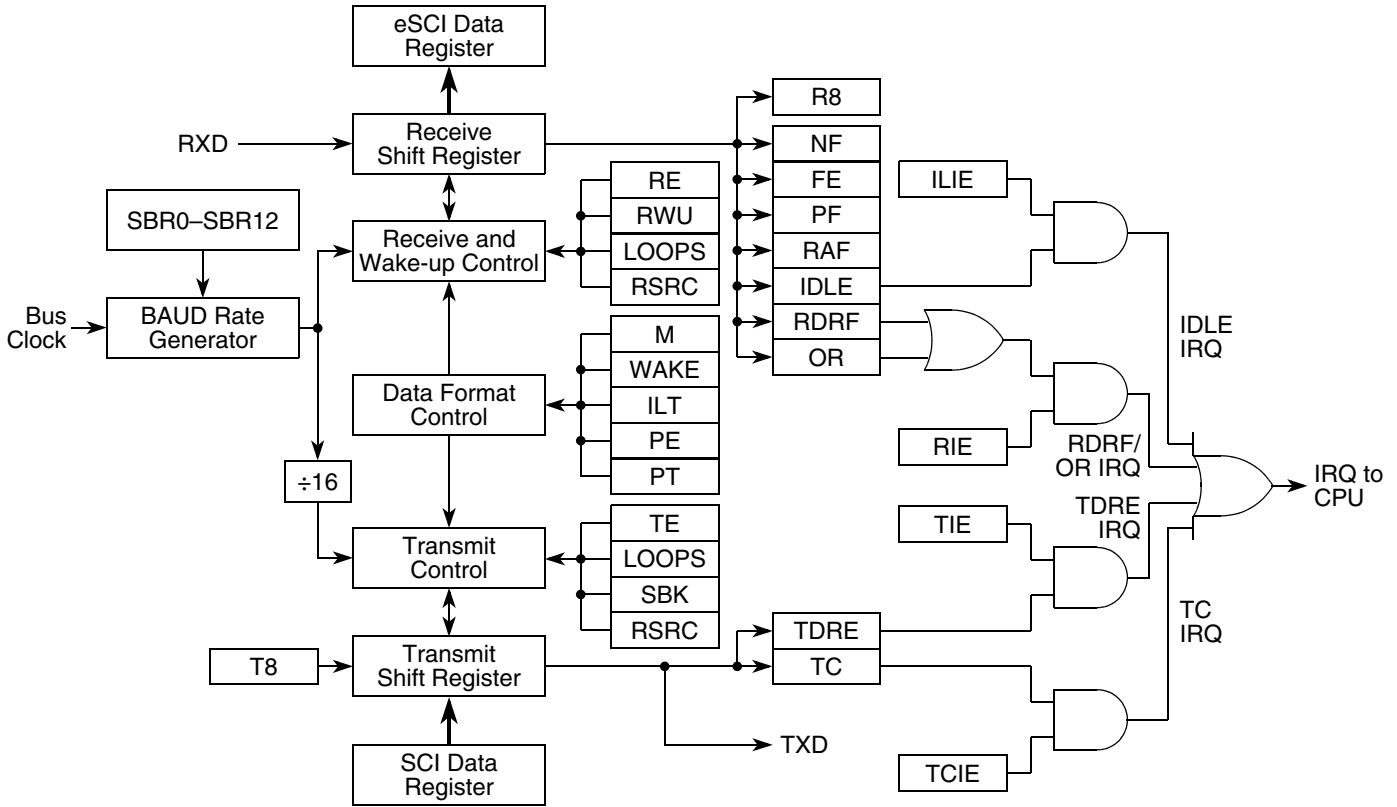

Figure 20-11. eSCI Operation Block Diagram

20.4.2 Data Format

The eSCI uses the standard NRZ mark/space data format. Each data character is contained in a frame that includes a start bit, eight or nine data bits, and a stop bit. Clearing the M bit in eSCI control register 1 configures the eSCI for 8-bit data characters. A frame with eight data bits has a total of 10 bits. Setting the M bit configures the eSCI for 9-bit data characters. A frame with nine data bits has a total of 11 bits.

When the eSCI is configured for 9-bit data characters, the ninth data bit is the T8 bit in the eSCI data register (ESCIx_DR). It remains unchanged after transmission and can be used repeatedly without rewriting it. A frame with nine data bits has a total of 11 bits.

The two different data formats are illustrated in Figure 20-12. Table 20-15 and Table 20-16 show the number of each type of bit in 8-bit data format and 9-bit data format, respectively.

Figure 20-12. eSCI Data Formats

Table 20-15. Example of 8-bit Data Formats

Start Bit	Data Bits	Address Bits	Parity Bits	Stop Bit
1	8	0	0	1
1	7	0	1	1
1	7	1 ¹	0	1

¹The address bit identifies the frame as an address character. Refer to [Section 20.4.5.6, "Receiver Wake-up."](#)

Table 20-16. Example of 9-Bit Data Formats

Start Bit	Data Bits	Address Bits	Parity Bits	Stop Bit
1	9	0	0	1
1	8	0	1	1
1	8	1 ¹	0	1

¹The address bit identifies the frame as an address character. Refer to [Section 20.4.5.6, "Receiver Wake-up."](#)

20.4.3 Baud Rate Generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value, 1 to 8191, written to the SBR0–SBR12 bits determines the system clock divider. The SBR bits are in the eSCI control register 1 (ESCIx_CR1). The baud rate clock is synchronized with the system clock and drives the receiver. The baud rate clock divided by 16 drives the transmitter. The receiver has an acquisition rate of 16 samples per bit time.

Baud rate generation is subject to one source of error when integer division of the system clock does not result in the exact target frequency.

[Table 20-17](#) lists some examples of achieving target baud rates with a system clock frequency of 128 MHz.

$$\text{SCI baud rate} = \frac{\text{System clock}}{16 \times \text{ESCIx_CR1[SBR]}}$$

Table 20-17. Baud Rates (Example: System Clock = 128 MHz)

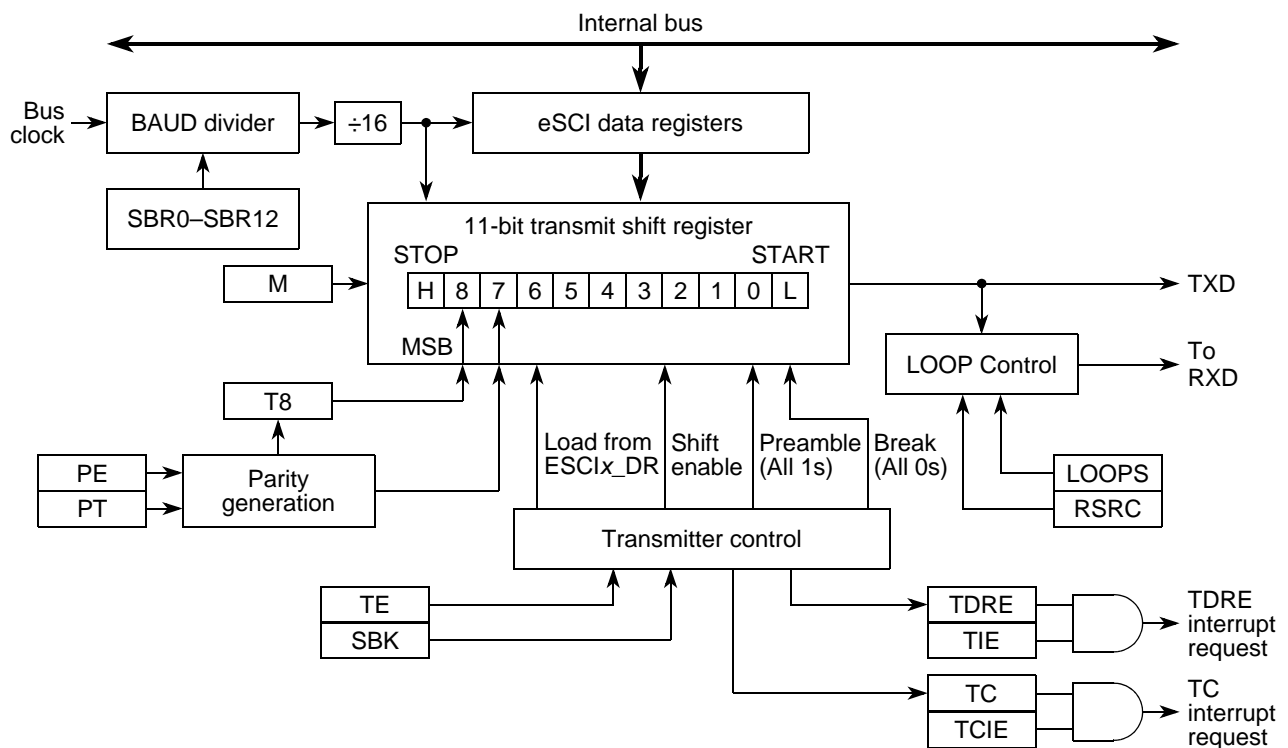

Bits SBR[0:12]	Receiver Clock (Hz)	Transmitter Clock (Hz)	Target Baud Rate	Error (%)
0x0023	3,657,143	228,571	230,400	-0.79
0x0045	1,855,072	115,942	115,200	+0.64
0x008B	920,863	57,554	57,600	-0.01
0x00D0	615,385	38,462	38,400	+0.16
0x01A1	306,954	19,185	19,200	-0.08

Table 20-17. Baud Rates (Example: System Clock = 128 MHz) (continued)

Bits SBR[0:12]	Receiver Clock (Hz)	Transmitter Clock (Hz)	Target Baud Rate	Error (%)
0x022C	230,216	14,388	14,400	-0.08
0x0341	153,661	9,604	9600	+0.04
0x0683	76,785	4,799	4800	-0.02
0x0D05	38,404	2,400.2	2400	+0.01
0x1A0A	19,202	1,200.1	1200	+0.01

20.4.4 Transmitter

Figure 20-13 illustrates the features of the eSCI transmitter.

Figure 20-13. eSCI Transmitter Block Diagram

20.4.4.1 Transmitter Character Length

The eSCI transmitter can accommodate either 8-bit or 9-bit data characters. The state of the M bit in eSCI control register 1 (ESCIx_CR1) determines the length of data characters. When transmitting 9-bit data, bit T8 in the eSCI data register (ESCIx_DR) is the ninth bit (bit 8).

20.4.4.2 Character Transmission

To transmit data, the MCU writes the data bits to the eSCI data register (ESCIx_DR), which in turn are transferred to the transmit shift register. The transmit shift register then shifts a frame out through the TXD signal, after it has prefaced them with a start bit and appended them with a stop bit. The eSCI data register (ESCIx_DR) is the buffer (write-only during transmit) between the internal data bus and the transmit shift register.

The eSCI also sets a flag, the transmit data register empty flag (TDRE), every time it transfers data from the buffer (ESCIx_DR) to the transmit shift register. The transmit driver routine can respond to this flag by writing another byte to the transmitter buffer (ESCIx_DR), while the shift register is still shifting out the first byte.

To initiate an eSCI transmission:

1. Configure the eSCI:
 - a) Turn on the module by clearing ESCIx_CR2[MDIS] if this bit is set.
 - b) Select a baud rate. Write this value to the eSCI control register 1 (ESCIx_CR1) to start the baud rate generator. Remember that the baud rate generator is disabled when the ESCIx_CR1[SBR] field is zero. When using 8-bit writes, writes to the ESCIx_CR1[0–7] have no effect without also writing to ESCIx_CR1[8–15].
 - c) Write to ESCIx_CR1 to configure word length, parity, and other configuration bits (LOOPS, RSRC, M, WAKE, ILT, PE, PT).
 - d) Enable the transmitter, interrupts, receive, and wake-up as required, by writing to the ESCIx_CR1 register bits (TIE, TCIE, RIE, ILIE, TE, RE, RWU, SBK). A preamble or idle character is shifted out of the transmitter shift register.

NOTE

A single 32-bit write to ESCI_CR1 can be used to perform steps b–d above.

2. Transmit procedure for each byte:
 - a) Poll the TDRE flag by reading the ESCIx_SR or responding to the TDRE interrupt. Keep in mind that the TDRE bit resets to 1.
 - b) If the TDRE flag is set, software should then clear it, followed by writing the data to be transmitted to ESCIx_DR, where the ninth bit is written to the T8 bit in ESCIx_DR if the eSCI is in 9-bit data format.
3. Repeat step 2 for each subsequent transmission.

NOTE

The TDRE flag is set when the shift register is loaded with the next data to transmit from ESCIx_DR, which occurs approximately half-way through the stop bit of the previous frame. This transfer occurs 9/16ths of a bit time AFTER the start of the stop bit of the previous frame.

Toggling the TE bit from 0 to 1 automatically loads the transmit shift register with a preamble of 10 logic 1s (if M = 0) or 11 logic 1s (if M = 1). After the preamble shifts out, control logic transfers the data from the eSCI data register into the transmit shift register. A logic 0 start bit automatically goes into the least significant bit position of the transmit shift register. A logic 1 stop bit goes into the most significant bit position.

The eSCI hardware supports odd or even parity. When parity is enabled, the most significant bit (Msb) of the data character is the parity bit.

The transmit data register empty flag, TDRE, in the eSCI status register (ESCIx_SR) is set when the eSCI data register transfers a byte to the transmit shift register. The TDRE flag indicates that the eSCI data register can accept new data from the internal data bus. If the transmit interrupt enable bit (TIE), in eSCI control register 1 (ESCIx_CR1) is also set, the TDRE flag generates a transmit interrupt request.

When the transmit shift register is not transmitting a frame, the TXD output goes to the idle condition, logic 1. If at any time software clears the TE bit in eSCI control register 1 (ESCIx_CR1), the transmit enable signal goes low and the TXD output goes idle.

If software clears TE while a transmission is in progress (ESCIx_CR1[TC] = 0), the frame in the transmit shift register continues to shift out. To avoid accidentally cutting off the last frame in a message, always wait for TDRE to go high after the last frame before clearing TE.

To separate messages with preambles with minimum idle line time, use the following sequence between messages:

1. Write the last byte of the first message to ESCIx_DR.
2. Wait for the TDRE flag to go high, indicating the transfer of the last frame to the transmit shift register.
3. Queue a preamble by clearing and then setting the TE bit.
4. Write the first byte of the second message to ESCIx_DR.

20.4.4.3 Break Characters

Setting the break bit, SBK, in eSCI control register 1 (ESCIx_CR1) loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on the M bit in the eSCI control register 1 (ESCIx_CR1) and on the BRK13 bit in the eSCI control register 2 (ESCIx_CR2). As long as SBK is set, the transmitter logic continuously loads break characters into the transmit shift register. After software clears the SBK bit, the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next frame.

NOTE

LIN 2.0 now requires that a break character is always 13 bits long, so the BRK13 bit should always be set to 1. The eSCI works with BRK13=0, but it violates LIN 2.0.

The eSCI recognizes a break character when a start bit is followed by eight or nine logic 0 data bits and a logic 0 where the stop bit should be. Receiving a break character has the following effects on eSCI registers:

- Sets the framing error flag, FE.
- Sets the receive data register full flag, RDRF.
- Clears the eSCI data register (ESCIx_DR).
- Can set a flag: overrun (OR), noise flag (NF), parity error flag (PF), or the receiver active flag (RAF). For more details, Refer to [Section 20.3.3.4, “eSCI Status Register \(ESCIx_SR\).”](#)

20.4.4.4 Idle Characters

An idle character contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on the M bit in eSCI control register 1 (ESCIx_CR1). The preamble is a synchronizing idle character that begins the first transmission initiated after toggling the TE bit from 0 to 1.

If the TE bit is cleared during a transmission, the TXD output becomes idle after completion of the transmission in progress. Clearing and then setting the TE bit during a transmission queues an idle character to be sent after the frame currently being transmitted.

NOTE

When queueing an idle character, return the TE bit to logic 1 before the stop bit of the current frame shifts out through the TXD output. Setting the TE bit after the stop bit shifts out through the TXD output causes data previously written to the eSCI data register to be lost. Toggle the TE bit for a queued idle character while the TDRE flag is set and immediately before writing the next byte to the eSCI data register.

20.4.4.5 Fast Bit Error Detection in LIN Mode

Fast bit error detection has been designed to allow flagging of LIN bit errors while they occur, rather than flagging them after a byte transmission has completed. To use this feature, it is assumed a physical interface connects to the LIN bus as shown in [Figure 20-14](#).

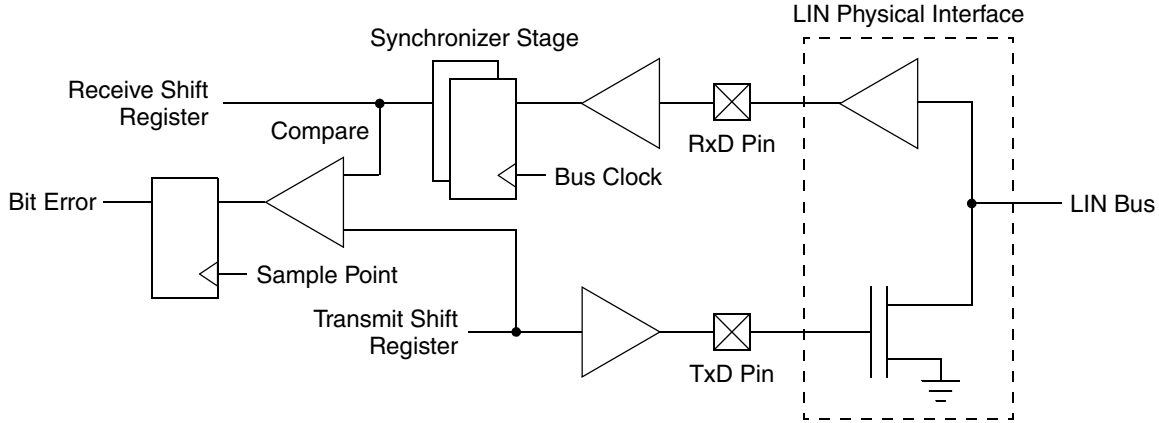

Figure 20-14. Fast Bit Error Detection on a LIN Bus

If fast bit error detection is enabled ($FBR = 1$), the eSCI compares the transmitted and the received data stream when the transmitter is active (not idle). After a mismatch between the transmitted data and the received data is detected the following actions are performed:

- The LIN frame is aborted (provided $LDBG=0$).
- The bit error flag BERR is set.
- If SBSTP is 0, the remainder of the byte is transmitted normally.
- If SBSTP is 1, the remaining bits in the byte after the error bit are transmitted as 1s (idle).

To adjust to different bus loads the sample point at which the incoming bit is compared to the one which was transmitted can be selected with the BESM13 bit (refer to [Figure 20-15](#)). If set, the comparison is performed at RT clock 13, otherwise at RT clock 9 (refer to [Section 20.4.5.3, “Data Sampling.”](#)).

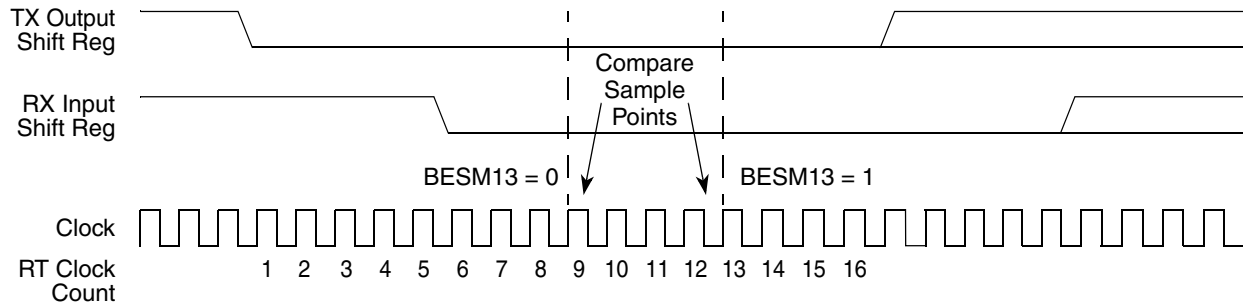

Figure 20-15. Fast Bit Error Detection Timing Diagram

20.4.5 Receiver

Figure 20-16 illustrates the eSCI receiver.

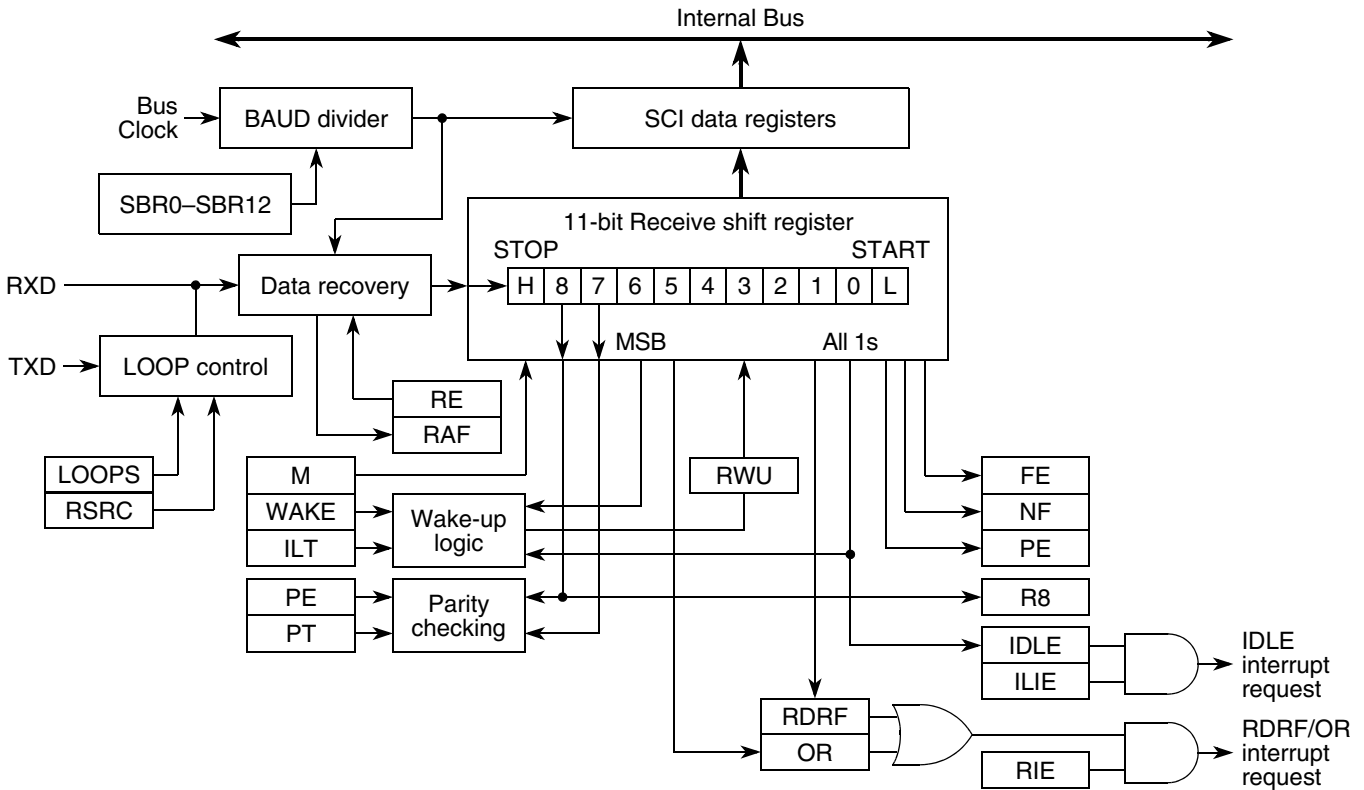

Figure 20-16. eSCI Receiver Block Diagram

20.4.5.1 Receiver Character Length

The eSCI receiver accepts 8-bit or 9-bit data characters. The state of the M bit in eSCI control register 1 (ESCI_x_CR1) determines the bit-length of data characters. When receiving 9-bit data, bit R8 in the eSCI data register (ESCI_x_DR) is the ninth bit (bit 8).

20.4.5.2 Character Reception

During an eSCI reception, the receive shift register shifts a frame in from the RXD input signal. The eSCI data register is the buffer (read-only during receive) between the internal data bus and the receive shift register.

After a complete frame shifts into the receive shift register, the data portion of the frame transfers to the eSCI data register. The receive data register full flag, RDRF, in eSCI status register (ESCI_x_SR) is then set, indicating that the received byte can be read. If the receive interrupt enable bit, RIE, in eSCI control register 1 (ESCI_x_CR1) is also set, the RDRF flag generates an RDRF interrupt request.

20.4.5.3 Data Sampling

The receiver uses a sampling clock to sample the RXD input signal at the 16 times the baud-rate frequency. This sampling clock is called the RT clock. To adjust for baud rate mismatch, the RT clock (Refer to Figure 20-17) is re-synchronized:

- After every start bit.
- After the receiver detects a data bit change from logic 1 to logic 0. This data bit change is detected when a majority of data samples return a valid logic 1 and a majority of the next data samples return a valid logic 0. Data samples are taken at RT8, RT9, and RT10, as shown in Figure 20-17.

To locate the start bit, eSCI data recovery logic performs an asynchronous search for a logic 0 preceded by three logic 1s. When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

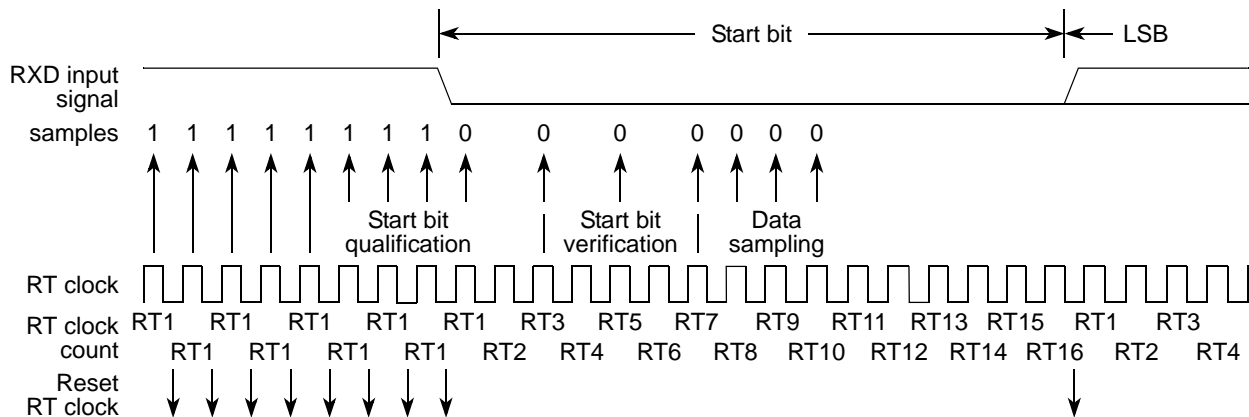

Figure 20-17. Receiver Data Sampling

To verify the start bit and to detect noise, the eSCI data recovery logic takes samples at RT3, RT5, and RT7. Table 20-18 summarizes the results of the start bit verification samples.

Table 20-18. Start Bit Verification

RT3, RT5, and RT7 Samples	Start Bit Verification	Noise Flag
000	Yes	0
001	Yes	1
010	Yes	1
011	No	0
100	Yes	1
101	No	0
110	No	0
111	No	0

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

To determine the value of a data bit and to detect noise, eSCI recovery logic takes samples at RT8, RT9, and RT10. [Table 20-19](#) summarizes the results of the data bit samples.

Table 20-19. Data Bit Recovery

RT8, RT9, and RT10 Samples	Data Bit Determination	Noise Flag
000	0	0
001	0	1
010	0	1
011	1	1
100	0	1
101	1	1
110	1	1
111	1	0

NOTE

The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (NF) is set.

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. [Table 20-20](#) summarizes the results of the stop bit samples.

Table 20-20. Stop Bit Recovery

RT8, RT9, and RT10 Samples	Framing Error Flag	Noise Flag
000	1	0
001	1	1
010	1	1
011	0	1
100	1	1
101	0	1
110	0	1
111	0	0

In Figure 20-18 the verification samples RT3 and RT5 determine that the first low detected was noise and not the beginning of a start bit. The RT clock is reset and the start bit search begins again. The noise flag is not set because the noise occurred before the start bit was found.

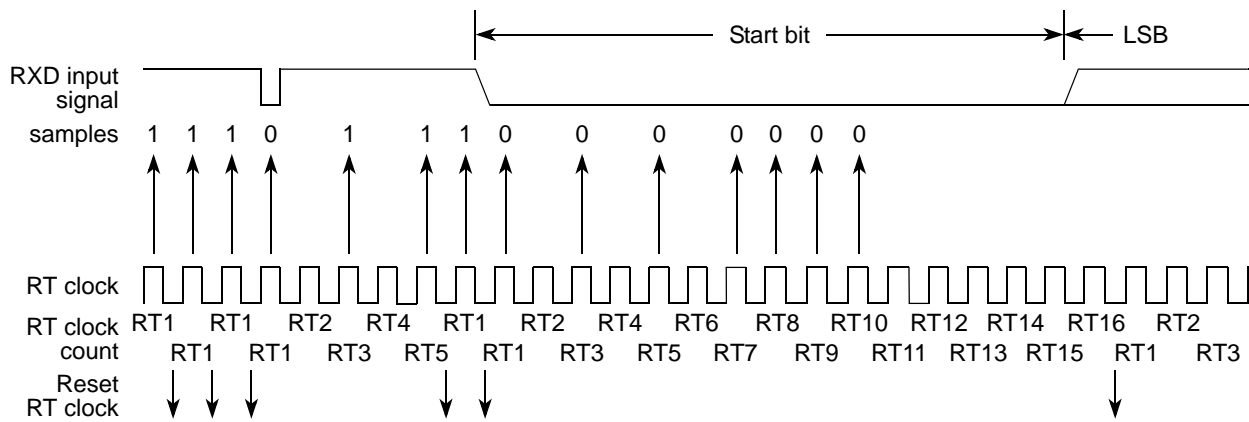

Figure 20-18. Start Bit Search Example

20.4.5.4 Framing Errors

If the data recovery logic sets the framing error flag, ESCIx_SR[FE], it does not detect a logic 1 where the stop bit should be in an incoming frame. A break character also sets the FE flag because a break character has no stop bit. The FE flag is set at the same time that the RDRF flag is set.

20.4.5.5 Baud Rate Tolerance

When a transmitting device operates at a baud rate below or above the receiver baud rate, accumulated bit-time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the stop bit. A noise error occurs if the RT8, RT9, and RT10 samples are not all the same logical values. A framing error occurs if the receiver clock is misaligned such that the majority of the RT8, RT9, and RT10 stop bit samples are a logic zero.

The receiver samples an incoming frame and re-synchronizes the RT clock on any valid falling edge within the frame. Re-synchronization within frames corrects a misalignment between transmitter bit times and receiver bit times.

20.4.5.5.1 Slow Data Tolerance

Figure 20-19 shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

Figure 20-19. Slow Data

For an 8-bit data character, data sampling of the stop bit takes the receiver RT clock 151 clock cycles, as is shown below:

$$9 \text{ bit times} \times 16 \text{ RT cycles} + 7 \text{ RT cycles} = 151 \text{ RT cycles}$$

With the misaligned character shown in Figure 20-19, the receiver counts 151 RT cycles at the point when the count of the transmitting device is 9 bit times x 16 RT cycles = 144 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is 4.63%, as is shown below:

$$\frac{151 - 144}{151} \times 100 = 4.63\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 167 RT cycles, as is shown below:

$$10 \text{ bit times} \times 16 \text{ RT cycles} + 7 \text{ RT cycles} = 167 \text{ RT cycles}$$

With the misaligned character shown in Figure 20-19, the receiver counts 167 RT cycles at the point when the count of the transmitting device is 10 bit times x 16 RT cycles = 160 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is 4.19%, as is shown below:

$$\frac{167 - 160}{167} \times 100 = 4.19\%$$

20.4.5.5.2 Fast Data Tolerance

Figure 20-20 shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.

Figure 20-20. Fast Data

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles, as is shown below:

$$9 \text{ bit times} \times 16 \text{ RT cycles} + 10 \text{ RT cycles} = 154 \text{ RT cycles}$$

With the misaligned character shown in Figure 20-20, the receiver counts 154 RT cycles at the point when the count of the transmitting device is 10 bit times \times 16 RT cycles = 160 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is 3.40%, as is shown below:

$$\frac{160 - 154}{160} \times 100 = 3.40\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles, as shown below:

$$10 \text{ bit times} \times 16 \text{ RT cycles} + 10 \text{ RT cycles} = 170 \text{ RT cycles}$$

With the misaligned character shown in Figure 20-20, the receiver counts 170 RT cycles at the point when the count of the transmitting device is 11 bit times \times 16 RT cycles = 176 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is 3.40%, as is shown below:

$$\frac{176 - 170}{176} \times 100 = 3.40\%$$

20.4.5.6 Receiver Wake-up

The receiver can be put into a standby state, which disregards all input requests targeted for other receivers in multiple-receiver systems. Setting the receiver wake-up bit (RWU) in eSCI control register 1

(ESCIx_CR1) puts the receiver into the standby state, which disregards all receiver interrupts. The eSCI loads the received data into the ESCIx_DR, but does not set the receive data register full (RDRF) flag.

The transmitting device can address messages to selected receivers by including addressing information (address bits) in the initial frame or frames of each message. Refer to section [Section 20.4.2, “Data Format,”](#) for an example of address bits.

The WAKE bit in eSCI control register 1 (ESCIx_CR1) determines how the eSCI is brought out of the standby state to process an incoming message. The WAKE bit enables either idle line wake-up or address mark wake-up.

20.4.5.6.1 Idle Input Line Wake-up (WAKE = 0)

Using the receiver idle input line wake-up method allows an idle condition on the RXD signal clears the ESCIx_CR1[RWU] bit and wakes up the eSCI. The initial frame or frames of every message contain addressing information. All receivers evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its RWU bit and return to the standby state. The RWU bit remains set and the receiver remains on standby until another idle character appears on the RXD signal.

Idle line wake-up requires that messages be separated by at least one idle character and that no message contains idle characters.

The idle character that wakes a receiver does not set the receiver idle bit, ESCIx_SR[IDLE], or the receive data register full flag, RDRF.

The idle line type bit, ESCIx_CR1[ILT], determines whether the receiver begins counting logic 1s as idle character bits after the start bit or after the stop bit.

20.4.5.6.2 Address Mark Wake-up (WAKE = 1)

Using the address mark wake-up method allows a logic 1 in the most significant bit (MSB) position of a frame to clear the RWU bit and wake-up the eSCI. The logic 1 in the msb position marks a frame as an address frame that contains addressing information. All receivers evaluate the addressing information, and the receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its RWU bit and return to the standby state. The RWU bit remains set and the receiver remains on standby until another address frame appears on the RXD signal.

The logic 1 msb of an address frame clears the receiver's RWU bit before the stop bit is received and sets the RDRF flag.

Address mark wake-up allows messages to contain idle characters but requires that the msb be reserved for use in address frames.

NOTE

With the WAKE bit clear, setting the RWU bit after the RXD signal has been idle can cause the receiver to wake-up immediately.

20.4.6 Single-Wire Operation

Normally, the eSCI uses two pins for transmitting and receiving. In single-wire operation, the RXD pin is disconnected from the eSCI. The eSCI uses the TXD pin for both receiving and transmitting.

Figure 20-21. Single-Wire Operation (LOOPS = 1, RSRC = 1)

Enable single-wire operation by setting the LOOPS bit and the receiver source bit, RSRC, in eSCI control register 1 (ESCLx_CR1). Setting the LOOPS bit disables the path from the RXD signal to the receiver. Setting the RSRC bit connects the receiver input to the output of the TXD pin driver.

During reception, both the transmitter and receiver must be enabled ($TE = 1$ and $RE = 1$). The SIU_PCR89[PA] and SIU_PCR91[PA] bits must be set to select the TXD function for the relevant eSCI module, and the TXD pin should be set for open drain operation (SIU_PCR nn [ODE] = 1). Optionally, if the external transmitting device is also open drain, a weak pullup can be enabled.

Refer to [Section 6.3.1.12, “Pad Configuration Registers \(SIU_PCR\)”](#).

During transmission, the transmitter must be enabled ($TE = 1$); the receiver can be enabled or disabled. If the receiver is enabled ($RE = 1$), transmissions are echoed back on the receiver. Set or clear open drain output enable depending on desired operation.

20.4.7 Loop Operation

In loop operation the transmitter output goes to the receiver input. The RXD signal is disconnected from the eSCI.

Figure 20-22. Loop Operation (LOOPS = 1, RSRC = 0)

Enable loop operation by setting the LOOPS bit and clearing the RSRC bit in eSCI control register 1 (ESCLx_CR1). Setting the LOOPS bit disables the path from the RXD signal to the receiver. Clearing the RSRC bit connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled ($TE = 1$ and $RE = 1$).

20.4.8 Modes of Operation

20.4.8.1 Run Mode

Run mode is the normal operating mode.

20.4.8.2 Disabling the eSCI

The module disable bit (ESCIx_CR2[MDIS]) in the eSCI control register 2 can be used to turn off the eSCI. This saves power by stopping the eSCI core from being clocked. By default the eSCI is enabled (ESCIx_CR2[MDIS]=0).

20.4.9 Interrupt Operation

Only the eSCI originates interrupt requests. The following sections describe how the eSCI generates a request and how the MCU acknowledges that request. The eSCI only has a single interrupt line (eSCI interrupt signal, active high operation) and all the following interrupts, when generated, are ORed together and issued through that port.

20.4.9.1 Interrupt Sources

There are several interrupt sources that can generate an eSCI interrupt to the CPU. They are listed with details and descriptions in [Table 20-21](#).

Table 20-21. eSCI Interrupt Flags, Sources, Mask Bits, and Descriptions

Interrupt Source	Flag	Description	Source	Local Enable
Transmitter	TDRE	Indicates that a byte was transferred from ESCIx_DR to the transmit shift register. The transmit data register empty (TDRE) interrupt is set high by the eSCI when the transmit shift register receives data, 8 or 9 bits, from the eSCI data register, ESCIx_DR. A TDRE interrupt indicates that the transmit data register (ESCIx_DR) is empty and that a new data can be written to the ESCIx_DR for transmission. The TDRE bit is cleared by writing a one to the TDRE bit location in the ESCIx_SR.	ESCIx_SR[0]	TIE
Transmitter	TC	Indicates that a transmit is complete. The transmit complete (TC) interrupt is set by the eSCI when a transmission has completed. A TC interrupt indicates that there is no transmission in progress. TC is set high when the TDRE flag is set and no data, preamble, or break character is being transmitted. When TC is set, the TXD pin becomes idle (logic 1). The TC bit is cleared by writing a one to the TC bit location in the ESCIx_SR.	ESCIx_SR[1]	TCIE

Table 20-21. eSCI Interrupt Flags, Sources, Mask Bits, and Descriptions (continued)

Interrupt Source	Flag	Description	Source	Local Enable
Receiver	RDRF	Indicates that received data is available in the eSCI data register. The receive data register full (RDRF) interrupt is set when the data in the receive shift register transfers to the eSCI data register. An RDRF interrupt indicates that the received data has been transferred to the eSCI data register and that the received data can now be read by the MCU. The RDRF bit is cleared by writing a one to the RDRF bit location in the ESCIx_SR.	ESCIx_SR[2]	RIE
Receiver	IDLE	Indicates that receiver input has become idle. The idle line (IDLE) interrupt is set when 10 consecutive logic 1s (if M = 0) or 11 consecutive logic 1s (if M = 1) appear on the receiver input. After the IDLE is cleared, a valid frame must again set the RDRF flag before an idle condition can set the IDLE flag. The IDLE bit is cleared by writing a one to the IDLE bit location in the ESCIx_SR.	ESCIx_SR[3]	ILIE
Receiver	OR	Indicates that an overrun condition has occurred. The overrun (OR) interrupt is set when software fails to read the eSCI data register before the receive shift register receives the next frame. The newly acquired data in the shift register is lost in this case, but the data already in the eSCI data registers is not affected. The OR bit is cleared by writing a one to the OR bit location in the ESCIx_SR.	ESCIx_SR[4]	ORIE
Receiver	NF	Detect noise error on receiver input. The NF interrupt is set when the eSCI detects noise on the receiver input.	ESCIx_SR[5]	NFIE
Receiver	FE	Framing error has occurred. The interrupt is set when the stop bit is read as a 0; which violates the SCI protocol. FE is cleared by writing it with 1.	ESCIx_SR[6]	FEIE
Receiver	PF	Parity of received data does not match parity bit; parity error has occurred. The interrupt is set when the parity of the received data is not correct. PF is cleared by writing it with 1.	ESCIx_SR[7]	PFIE
LIN	BERR	Detected a bit error, only valid in LIN mode. While the eSCI is in LIN mode, the bit error (BERR) flag is set when one or more bits in the last transmitted byte is not read back with the same value. The BERR flag is cleared by writing a 1 to the bit. A bit error causes the LIN FSM to reset. Clear the BERR flag by writing a 1 to the bit.	ESCIx_SR[11]	IEBERR
LIN	RXRDY	Indicates LIN hardware has received a data byte. While in LIN mode, the receiver ready (RXRDY) flag is set when the eSCI receives a valid data byte in an RX frame. RXRDY is not set for bytes which the receiver obtains by reading back the data which the LIN finite state machine (FSM) has sent out. Clear the RXRDY flag by writing a 1 to the bit.	ESCIx_SR[16]	RXIE
LIN	TXRDY	Indicates LIN hardware can accept a control or data byte. While in LIN mode, the transmitter ready (TXRDY) flag is set when the eSCI can accept a control or data byte. Clear the TXRDY flag by writing a 1 to the bit.	ESCIx_SR[17]	TXIE

Table 20-21. eSCI Interrupt Flags, Sources, Mask Bits, and Descriptions (continued)

Interrupt Source	Flag	Description	Source	Local Enable
LIN	LWAKE	A wake-up character has been received from a LIN frame. The LIN wake-up (LWAKE) flag is set when the LIN hardware receives a wake-up character sent by one of the LIN slaves. This occurs only when the LIN bus is in sleep mode. Clear the LWAKE flag by writing a 1 to the bit.	ESCIx_SR[18]	WUIE
LIN	STO	The response of the slave has been too slow (slave timeout). The slave timeout (STO) flag is set during an RX frame when the LIN slave has not transmitted all requested data bytes before the specified timeout period. Clear the STO flag by writing a 1 to the bit.	ESCIx_SR[19]	STIE
LIN	PBERR	Physical bus error detected. If the RXD input remains at the same value for 15 cycles after a transmission has started, the LIN hardware sets the physical bus error (PBERR) flag. Clear the PBERR flag by writing a 1 to the bit.	ESCIx_SR[20]	PBIE
LIN	CERR	CRC error detected. If an RX frame has the CRC checking flag set, and the two CRC bytes do not match the calculated CRC pattern, the CRC error (CERR) flag is set. Clear the CERR flag by writing a 1 to the bit.	ESCIx_SR[21]	CIE
LIN	CKERR	Checksum error detected. If an RX frame has the checksum checking flag set and the last byte does not match the calculated checksum, the checksum error (CKERR) flag is set. Clear the CKERR flag by writing a 1 to the bit.	ESCIx_SR[22]	CKIE
LIN	FRC	LIN frame completed. The frame complete (FRC) flag is set after the last byte of a TX frame is transmitted, or after the last byte of an RX frame is received. The FRC flag indicates that the next frame can be set up. Clear the FRC flag by writing a 1 to the bit. Note: The last byte of an outgoing TX frame or incoming RX frame indicates that the checksum comparison occurred. Note: It is possible to set the FRC flag before the DMA controller has completed transferring the last byte from the eSCI port to system memory. Do not set the FRC flag if the frame will be processed. For frames that will be processed, use the DMA controller interrupt.	ESCIx_SR[23]	FCIE
LIN	OVFL	ESCIx_LRR overflow. The overflow (OVFL) flag is set when a byte is received in the ESCIx_LRR before the previous byte is read. Since the system is responsible for reading the register before the next byte arrives, this condition indicates a problem with CPU load. The OVFL flag is cleared by writing a 1 to the bit.	ESCIx_SR[31]	OFIE

20.4.10 Using the LIN Hardware

The eSCI provides special support for the LIN protocol. It can be used to automate most tasks of a LIN master. In conjunction with the DMA interface it is possible to transmit entire frames (or sequences of frames) and receive data from LIN slaves without any CPU intervention. There is no special support for LIN slave mode. If required, LIN slave mode can be implemented in software.

A LIN frame consists of a break character (10 or 13 bits), a sync field, an ID field, n data fields (n could be 0) and a checksum field. The data and checksum bytes are either provided by the LIN master (TX frame) or by the LIN slave (RX frame). The header fields are always generated by the LIN master.

Figure 20-23. Typical LIN frame

The LIN hardware is highly configurable. This configurability allows the eSCI's LIN hardware to generate frames for LIN slaves from all revisions of the LIN standard. The settings are adjusted according to the capabilities of the slave device.

To activate the LIN hardware, the LIN mode bit in the ESCIx_LCR needs to be set. Other settings, such as double stop flags after bit errors and automatic parity bit generation, are also available for use in LIN mode.

The eSCI settings must be made according to the LIN specification. The eSCI must be configured for 2-wire operation (2 wires connected to the LIN transceiver) with 8 data bytes and no parity. Normally a 13-bit break is used, but the eSCI can also be configured for 10-bit breaks as required by the application.

20.4.10.1 Features of the LIN Hardware

The eSCI's LIN hardware has several features to support different revisions of the LIN slaves. The ESCIx_LTR can be configured to include or not include header bits in the checksum on a frame by frame basis. This feature supports LIN slaves with different LIN revisions. The LIN control register allows the application to automatically calculate the parity bits in the ID field and insert double stop flags a bit error. The BRK13 bit in ESCIx_CR2 decides whether to generate 10 or 13 bit break characters.

NOTE

LIN 2.0 requires a 13-bit break character. Set the BRK13 bit to 1. The eSCI bus works when BRK13 = 0, but the setting does not comply with LIN 2.0.

The application software can disable checksum generation/verification for individual frames to perform the functions externally and use the LIN hardware to append two CRC bytes (Figure 20-24). Although the LIN standard does not include CRCs, CRCs are processed as data bytes by the LIN protocol. CRCs are used in software applications that process very large frames. The eSCI and FlexCAN modules use the same CRC polynomial, the LIN protocol processes CAN bytes as data bytes.

Figure 20-24. LIN Frame with CRC bytes

To force a resync of the LIN FSM, use the LRES bit in the LIN control register. Typically LIN hardware automatically discards the frame when a bit error is detected.

20.4.10.2 Generating a TX Frame

The following procedure describes how a basic TX frame is generated.

The frame is controlled via the LIN transmit register (ESCIx_LTR). Initially, the application software must check the TXRDY bit (either using an interrupt, the TX DMA interface, or by polling the LIN status register). If TXRDY is set, the register is writable. Before each write, TXRDY must be checked (though this step is performed automatically in DMA mode). The first write to the ESCIx_LTR must contain the LIN ID field. The next write to ESCIx_LTR specifies the length of the frame (0 to 255 Bytes). The third write to ESCIx_LTR contains the control byte (frame direction, checksum/CRC settings). Note that timeout bits are not included in TX frames, since they only refer to LIN slaves. The three previously mentioned writes to the ESCIx_LTR specify the LIN frame data. After the LIN frame data is specified, the eSCI LIN hardware starts to generate a LIN frame.

First, the eSCI transmits a break field. The sync field is transmitted next. The third field is the ID field. After these three fields have been broadcast, the ESCIx_LTR accepts data bytes; the LIN hardware transmits these data bytes as soon as they are available and can be sent out. After the last step the LIN hardware automatically appends the checksum field.

It is possible to set up a DMA channel to handle all the tasks required to send a TX frame. For this operation, the TX DMA channel must be activated by setting the ESCIx_CR2[TXDMA] bit. The control information for the LIN frame (ID, message length, TX/RX type, timeout, etc.) and the data bytes are stored at an appropriate memory location. The DMA controller is then set up to transfer this block of memory to a location (the ESCIx_LTR). After transmission is complete, either the DMA controller or the LIN hardware can generate an interrupt to the CPU.

NOTE

In contrast to the standard software implementation where each byte transmission requires several interrupts, the DMA controller and eSCI handle communication, bit error and physical bus error checking, checksum, and CRC generation (checking on the RX side).

Refer to [Figure 20-25](#) for more information.

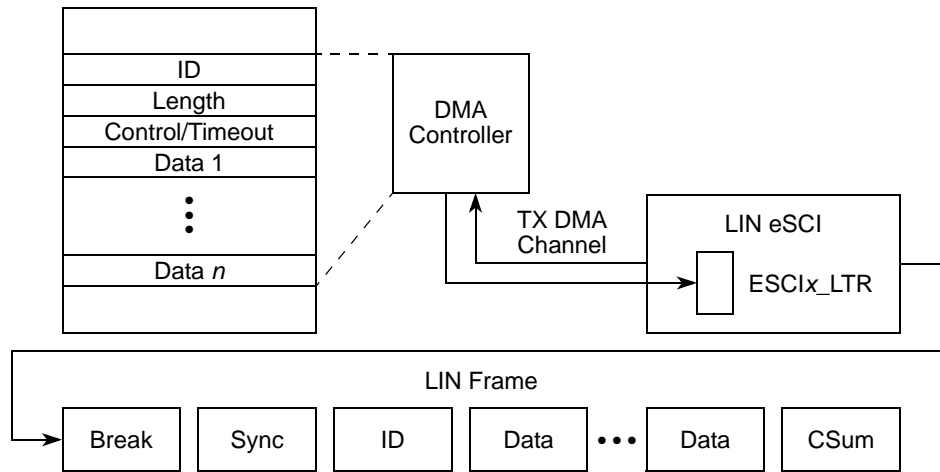

Figure 20-25. DMA Transfer of a TX frame

20.4.10.3 Generating an RX Frame

For RX frames the header information is provided by the LIN master. The data, CRC and checksum bytes (as enabled) are provided by the LIN slave. The LIN master verifies CRC and checksum bytes transmitted by the slave.

For an RX frame, control information must be written to the ESCIx_LTR in the same manner as for the TX frames. Additionally the timeout bits, which define the time to complete the entire frame, must be written. Then the ESCIx_SR[RXRDY] bit must be checked (either with an interrupt, RX DMA interface, or by polling) to detect incoming data bytes. The checksum byte normally does not appear in the ESCIx_LRR, instead the LIN hardware verifies the checksum and issue an interrupt, if the checksum value is not correct.

Two DMA channels can be used when executing an RX frame: one to transfer the header/control information from a memory location to the ESCIx_LTR, and one to transfer the incoming data bytes from the ESCIx_LRR to a table in memory. After the last byte from the RX frame has been stored, the DMA controller can indicate completion to the CPU.

NOTE

It is also possible to setup a whole sequence of RX and TX frames, and generate a single event at the end of that sequence.

Refer to [Figure 20-26](#) for more information.

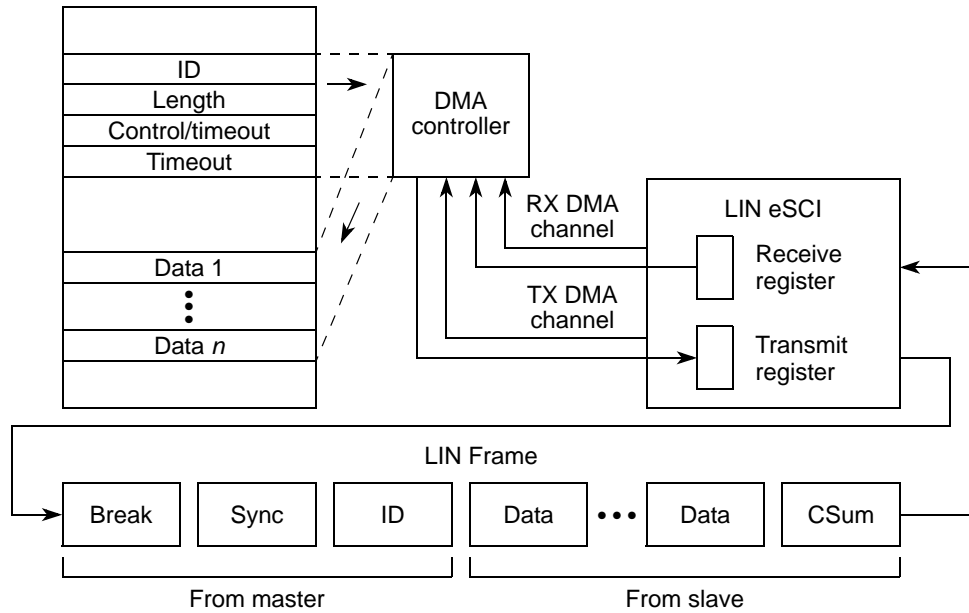

Figure 20-26. DMA Transfer of an RX frame

20.4.10.4 LIN Error Handling

The LIN hardware can detect several error conditions of the LIN protocol. LIN hardware receives all transmitted bytes, and compares the values with expected values to determine if the data is valid. If a mismatch occurs, a bit error is generated and the LIN FSM returns to its start state.

For an RX frame the LIN hardware can detect a slave timeout error. The exact slave timeout error value can be set via the timeout bits in the `ESCIx_LTR`. If the frame is not complete within the number of clock cycles specified in the register, the LIN FSM returns to its start state, and the `STO` interrupt is issued.

The LIN protocol supports a sleep mode. After 25,000 bus cycles of inactivity the bus is assumed to be in sleep mode. Normally entering sleep mode can be avoided, if the LIN master is regularly creating some bus activity. Otherwise the timeout state needs to be detected by the application software, for example by setting a timer.

Both LIN masters and LIN slaves can cause the bus to exit sleep mode by sending a break signal. The LIN hardware generates a break when the `WU` bit in the LIN control register is written. After transmitting the break, data is not sent out (`TXRDY = 0`) until the wake-up period expires. Define the wakeup period using the `WUD` bits in the LIN control register.

Break signals sent by a LIN slave are received by the LIN hardware, and so indicated by setting the `WAKE` flag in the LIN status register.

A physical bus error (LIN bus is permanently stuck at a fixed value) sets several error flags. If the input is permanently low, the eSCI sets the framing error (`FE`) flag in the eSCI status register. If the `RXD` input remains at the same value for 15 cycles after a transmission starts, the LIN hardware sets the `PBERR` flag in the LIN status register. A bit error can also occur.

20.4.10.5 LIN Setup

Since the eSCI is for general-purpose use, some of the settings are not applicable for LIN operation. The following setup applies for most applications, regardless of which kind of LIN slave is addressed:

1. Enable the module by clearing the ESCIx_CR2[MDIS] bit to 0.
2. Enable transmit and receive by setting ESCIx_CR1[TE] = 1, ESCIx_CR1[RE] = 1.
3. Clear the data format bit (ESCIx_CR1[M] = 0) to select 8 data bits, and disable the parity bit (PE = 0).
4. Use the LIN interrupts by clearing the interrupt enable bits: ESCIx_CR1[TIE], ESCIx_CR1[TCIE], and ESCIx_CR1[RIE]. Select LIN mode by setting ESCIx_LCR[LIN] = 1.
5. Set the break character (ESCIx_CR2[BRK13] = 1) to comply with the LIN standard requirements. The eSCI works when BRK13 = 0, but violates LIN 2.0.
6. Bit errors are commonly configured to: reset the LIN FSM, immediately stop bus transfers, and suspend DMA requests until the BERR flag is cleared. Use the following bit settings to perform these functions: ESCIx_LCR[LDBG] = 0, ESCIx_CR2[SBSTP] = 1, and ESCIx_CR2[BSTP] = 1.
7. Fast bit error detection provides superior error checking. Set ESCIx_CR2[FBR]; it is commonly used with ESCIx_CR2[BESM13] = 1.
8. If available, enable a pulldown on the RX input. (If the transceiver fails, the RX pin does not float).
9. Enable the following error indicators NF, FE, BERR, STO, PBERR, CERR, CKERR, and OVFL.
10. Transmit a wake-up character on the LIN bus to activate the LIN slaves.

Other settings like baud rate, length of break character etc., depend on the LIN slaves to which the eSCI is connected.

Chapter 21

FlexCAN2 Controller Area Network

21.1 Introduction

The device MCU contains three controller area network (FlexCAN2) modules. Each FlexCAN2 module is a communication controller implementing the CAN protocol according to CAN Specification version 2.0B and ISO Standard 11898. Each FlexCAN2 module contains a 1024-byte embedded memory, capable of storing up to 64 message buffers (MBs). The respective functions are described in subsequent sections.

Each FlexCAN module contains two embedded memories, one a 1056-byte embedded memory, capable of storing 64 Message Buffers (MB), the other for storing RX individual mask registers.

This FlexCAN2 version implements individual mask registers and a reception queue thereby allowing queuing of received frames before requiring interrupt processing. Also included is a feature for disabling self-reception of TX frames.

21.1.1 Block Diagram

A general block diagram is shown in [Figure 21-1](#), which describes the main submodules implemented in the FlexCAN2 module, including an embedded RAM for up to 64 message buffers.

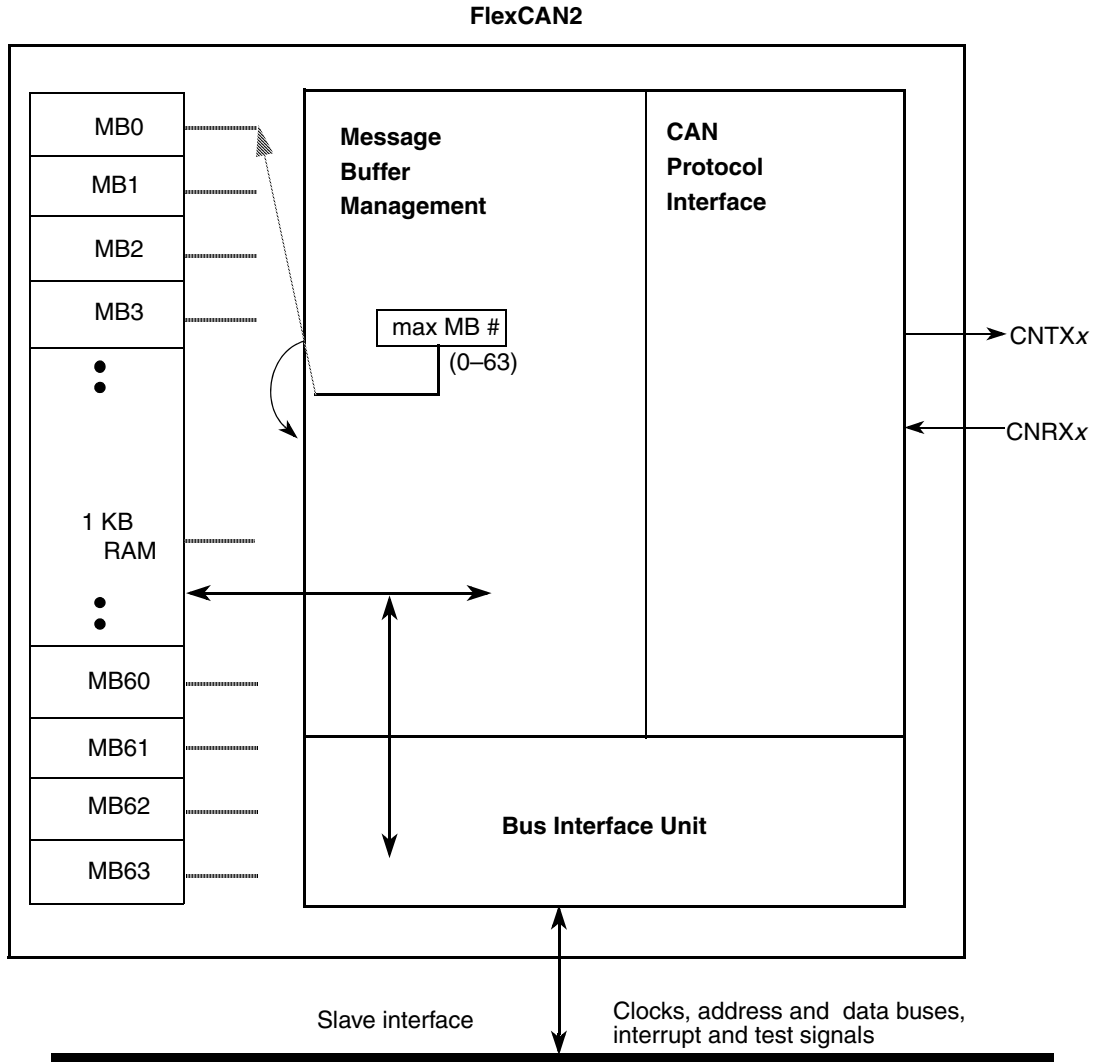

Figure 21-1. FlexCAN2 Block Diagram

21.1.2 Overview

The CAN protocol was designed primarily, but not exclusively, to be used as a vehicle serial data bus, meeting the specific requirements of this field: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness and required bandwidth. The FlexCAN2 module is a full implementation of the CAN protocol specification, Version 2.0 B, which supports both standard and extended message frames. Sixty-four message buffers (MBs) are stored in an embedded 1024-byte RAM dedicated to the FlexCAN2 module.

The CAN protocol interface (CPI) manages the serial communication on the CAN bus, requesting RAM access for receiving and transmitting message frames, validating received messages and performing error handling. The message buffer management (MBM) handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms. The bus interface unit (BIU) controls the access to and from the internal interface bus, to establish connection to the CPU and to any other modules. Clocks, address and data buses, interrupt outputs and test signals are accessed through the bus interface unit.

21.1.3 Features

The FlexCAN2 module includes these distinctive features:

- Based on and includes all existing features of the Freescale TouCAN module
- Reception queue available by setting more than one RX message buffer with the same ID
- Programmable for either global (compatible with previous versions) or individual receive ID masking
- Maskable self-reception by setting MCR[SRXDIS]
- Full implementation of the CAN protocol specification, version 2.0B
 - Standard data and remote frames
 - Extended data and remote frames
 - Data length of 0 to 8 bytes
 - Programmable bit rate up to 1 Mb/sec
- Content-related addressing
- 64 flexible message buffers of 0 to 8 bytes data length
- Each MB configurable as RX or TX, all supporting standard and extended messages
- Includes 1024 bytes of RAM used for message buffer storage
- Programmable clock source to the CAN protocol interface, either system clock or oscillator clock
- Listen-only mode capability
- Programmable loop-back mode supporting self-test operation
- Programmable transmit-first scheme: lowest ID or lowest buffer number
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independent of the transmission medium (an external transceiver is assumed)
- Multi master concept
- High immunity to EMI
- Short latency time due to an arbitration scheme for high-priority messages

21.1.4 Modes of Operation

The device supports four FlexCAN functional modes: normal, freeze, listen-only and loop-back. One low power mode, module disabled, is supported.

21.1.4.1 Normal Mode

In normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally and all the CAN protocol functions are enabled. In this device, there is no distinction between user and supervisor modes.

21.1.4.2 Freeze Mode

Freeze mode is entered when the FRZ bit in the module configuration register (CAN_x_MCR) is asserted while the HALT bit in the CAN_x_MCR is set or debug mode is requested by the NPC. In freeze mode no transmission or reception of frames is done, and synchronization with the CAN bus is lost. Refer to [Section 21.4.6.1, “Freeze Mode,”](#) for more information.

21.1.4.3 Listen-Only Mode

The module enters this mode when the LOM bit in the CAN_x_CR is asserted. In this mode, FlexCAN operates in a CAN error passive mode, freezing all error counters and receiving messages without sending acknowledgments.

21.1.4.4 Loop-Back Mode

The module enters this mode when the LPB bit in the CAN_x_CR is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The CAN receive input pin (CNRX_x) is ignored and the transmit output (CNTX_x) goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

21.1.4.5 Module Disabled Mode

This low power mode is entered when the MDIS bit in the CAN_MCR is asserted. When disabled, the module shuts down the clocks to the CAN protocol interface and message buffer management submodules. Exit from this mode is done by negating the CAN_MCR[MDIS] bit. Refer to [Section 21.4.6.2, “Module Disabled Mode,”](#) for more information.

21.2 External Signal Description

21.2.1 Overview

The FlexCAN2 module has two I/O signals connected to the external MCU pins. These signals are summarized in [Table 21-1](#) and described in more detail in the next sub-sections.

Table 21-1. FlexCAN2 Signals

Signal Name ¹	Direction	Description
CNRX _x	I	CAN receive
CNTX _x	O	CAN transmit

¹ x indicates FlexCAN2 module A, B, or C.

21.2.2 Detailed Signal Description

21.2.2.1 CNRX_x

This pin is the receive pin to the CAN bus transceiver. The dominant state is represented by logic level 0. The recessive state is represented by logic level 1.

21.2.2.2 CNTX_x

This pin is the transmit pin to the CAN bus transceiver. The dominant state is represented by logic level 0. The recessive state is represented by logic level 1.

21.3 Memory Map/Register Definition

This section describes the registers and data structures in the FlexCAN2 module. The addresses presented here are relative to the base address of the module.

The address space occupied by FlexCAN2 is continuous: 128 bytes for registers starting at the module base address, extra space for MB storage, and 1024 bytes for 64 MBs.

21.3.1 Memory Map

The complete memory map for a FlexCAN2 module with its 64 MBs is shown in [Table 21-2](#). Except for the base addresses, the three FlexCAN2 modules have identical memory maps. Each individual register is identified by its complete name and the corresponding mnemonic.

Table 21-2. Module Memory Map

Address	Register Name	Register Description	Bits
Base = 0xFFFC_0000 (FlexCAN A) Base = 0xFFFC_4000 (FlexCAN B) Base = 0xFFFC_8000 (FlexCAN C)	CAN _x _MCR	Module configuration register	32
Base + 0x0004	CAN _x _CR	Control register	32
Base + 0x0008	CAN _x _TIMER	Free running timer	32
Base + 0x000C	—	Reserved	—
Base + 0x0010	CAN _x _RXGMASK	RX global mask	32
Base + 0x0014	CAN _x _RX14MASK	RX buffer 14 mask	32
Base + 0x0018	CAN _x _RX15MASK	RX buffer 15 mask	32

Table 21-2. Module Memory Map (continued)

Address	Register Name	Register Description	Bits
Base + 0x001C	CANx_ECR	Error counter register	32
Base + 0x0020	CANx_ESR	Error and status register	32
Base + 0x0024	CANx_IMRH	Interrupt masks high register	32
Base + 0x0028	CANx_IMRL	Interrupt masks low register	32
Base + 0x002C	CANx_IFRH	Interrupt flags high register	32
Base + 0x0030	CANx_IFRL	Interrupt flags low register	32
Base + 0x0034–Base + 0x005F	—	Reserved	—
Base + 0x0060–Base + 0x007F	—	Reserved	—
Base + 0x0080–Base + 0x017F	MB0–MB15	Message buffers 0–15	128 bits per MB
Base + 0x0180–Base + 0x027F	MB16–MB31	Message buffers 16–31	128 bits per MB
Base + 0x0280–Base + 0x047F	MB32–MB63	Message buffers 32–63	128 bits per MB
Base + 0x0880–Base + 0x08BF	CANx_RXIMR0–CANx_RXIMR15	RX individual mask register 0–15	32
Base + 0x08C0–Base + 0x08FF	CANx_RXIMR16–CANx_RXIMR31	RX individual mask register 16–31	32
Base + 0x0900–Base + 0x097F	CANx_RXIMR32–CANx_RXIMR63	RX individual mask register 32–63	32

The FlexCAN2 module stores CAN messages for transmission and reception using a message buffer structure. Each individual MB is formed by 16 bytes of memory mapped as described in [Table 21-3](#). The FlexCAN2 module can manage up to 64 message buffers. [Table 21-3](#) shows the standard and extended message buffer (MB0) memory map, using 16 bytes (0x80–0x8F) total space.

Table 21-3. Message Buffer MB0 Memory Mapping

Address Offset	MB Field
0x80	Control and status (C/S)
0x84	Identifier field
0x88–0x8F	Data fields 0–7 (1 byte each)

NOTE

Reading the C/S word of a message buffer (the first word of each MB) will lock it, preventing it from receiving further messages until it is unlocked either by reading another MB or by reading the timer.

21.3.2 Message Buffer Structure

The message buffer structure used by the FlexCAN2 module is represented in [Figure 21-2](#). Both extended and standard frames (29-bit identifier and 11-bit identifier, respectively) used in the CAN specification (version 2.0 Part B) are represented.

Figure 21-2. Message Buffer Structure

Table 21-4. Message Buffer Field Descriptions

Name	Description
CODE	Message buffer code. This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN2 module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 21-5 and Table 21-6 . Refer to Section 21.4, “Functional Description,” for additional information.
SRR	Substitute remote request. Fixed recessive bit, used only in extended format. It must be set to ‘1’ by the user for transmission (TX Buffers) and will be stored with the value received on the CAN bus for RX receiving buffers. It can be received as either recessive or dominant. If FlexCAN2 receives this bit as dominant, then it is interpreted as arbitration loss. 0 Dominant is not a valid value for transmission in extended format frames 1 Recessive value is compulsory for transmission in extended format frames
IDE	ID extended bit. This bit identifies whether the frame format is standard or extended. 0 Frame format is standard 1 Frame format is extended
RTR	Remote transmission request. This bit is used for requesting transmissions of a data frame. If FlexCAN2 transmits this bit as ‘1’ (recessive) and receives it as ‘0’ (dominant), it is interpreted as arbitration loss. If this bit is transmitted as ‘0’ (dominant), then if it is received as ‘1’ (recessive), the FlexCAN2 module treats it as bit error. If the value received matches the value transmitted, it is considered as a successful bit transmission. 0 Indicates the current MB has a data frame to be transmitted 1 Indicates the current MB has a remote frame to be transmitted
LENGTH	Length of data in bytes. This 4-bit field is the length (in bytes) of the RX or TX data, which is located in offset 0x8 through 0xF of the MB space (refer to Figure 21-2). In reception, this field is written by the FlexCAN2 module, copied from the DLC (data length code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the Frame to be transmitted is a remote frame and does not include the data field, regardless of the length field.
TIME STAMP	Free-running counter time stamp. This 16-bit field is a copy of the free-running timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.
ID	Frame identifier. Standard frame format, only the 11 most significant bits (3 to 13) are used for frame identification in both receive and transmit cases. The 18 least significant bits (14 to 31) are ignored. Extended frame format, all bits are used for frame identification in both receive and transmit cases.
DATA	Data field. Up to eight bytes can be used for a data frame. For RX frames, the data is stored as it is received from the CAN bus. For TX frames, the CPU prepares the data field to be transmitted within the frame.

Table 21-5. Message Buffer Code for RX Buffers

RX Code before RX New Frame	Description	RX Code after RX New Frame	Comment
0000	NOT ACTIVE: MB is not active.	—	MB does not participate in the matching process.
0100	EMPTY: MB is active and empty.	0010	MB participates in the matching process. When a frame is received successfully, the code is automatically updated to FULL.
0010	FULL: MB is full.	0010	The act of reading the C/S word followed by unlocking the MB does not make the code return to EMPTY. It remains FULL. If a new frame is written to the MB after the C/S word was read and the MB was unlocked, the code still remains FULL.
		0110	If the MB is FULL and a new frame is overwritten to this MB before the CPU had time to read it, the code is automatically updated to OVERRUN. Refer to Section 21.4.3.1, "Matching Process" for details about overrun behavior.
0110	OVERRUN: A frame was overwritten into a full buffer.	0010	If the code indicates OVERRUN but the CPU reads the C/S word and then unlocks the MB, when a new frame is written to the MB the code returns to FULL.
		0110	If the code already indicates OVERRUN, and yet another new frame must be written, the MB will be overwritten again, and the code will remain OVERRUN. Refer to Section 21.4.3.1, "Matching Process" for details about overrun behavior.
0XY1 ¹	BUSY: FlexCAN is updating the contents of the MB. The CPU must not access the MB.	0010	An EMPTY buffer was written with a new frame (XY was 01).
		0110	A FULL/OVERRUN buffer was overwritten (XY was 11).

¹ Note that for TX MBs (refer to [Table 21-6](#)), the BUSY bit should be ignored upon read.

Table 21-6. Message Buffer Code for TX Buffers

RTR	Initial TX Code	Code after Successful Transmission	Description
X	1000	—	INACTIVE: MB does not participate in the arbitration process.
0	1100	1000	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
1	1100	0100	Transmit remote frame unconditionally once. After transmission, the MB automatically becomes and RX MB with the same ID.

Table 21-6. Message Buffer Code for TX Buffers (continued)

RTR	Initial TX Code	Code after Successful Transmission	Description
0	1010	1010	Transmit a data frame whenever a remote request frame with the same ID is received. This MB participates simultaneously in both the matching and arbitration processes. The matching process compares the ID of the incoming remote request frame with the ID of the MB. If a match occurs this MB is allowed to participate in the current arbitration process and the CODE field is automatically updated to '1110' to allow the MB to participate in future arbitration runs. When the frame is eventually transmitted successfully, the Code automatically returns to '1010' to restart the process again.
0	1110	1010	the MBM as a result of match to a remote request frame. The data frame will be transmitted unconditionally once and then the code will automatically return to '1010'. The CPU can also write this code with the same effect.

21.3.3 Register Descriptions

The FlexCAN2 registers are described in this section. Note that there are three separate, identical FlexCAN2 modules. Each register in the following sections is denoted with an 'x' that represents the specified module.

21.3.3.1 Module Configuration Register (CANx_MCR)

CANx_MCR defines global system configurations, such as the module operation mode and maximum message buffer configuration. Most of the fields in this register can be accessed at any time, except the MAXMB field, which should only be changed while the module is in freeze mode.

Address: Base + 0x0000

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R			0	HALT	NOTRDY	0	SOFTRST	FRZACK	1	0	WRN EN	MDISACK	0	0	SRX DIS	MBFEN
W																
Reset	0	1	0	1	1	0	0	1	1	0	0	0	0	0	0	0
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	MAXMB

Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Figure 21-3. Module Configuration Register (CANx_MCR)

Table 21-7. CANx_MCR Field Descriptions

Field	Description
0 MDIS	Module disable. Controls whether FlexCAN2 is enabled or not. When disabled, FlexCAN2 shuts down the clock to the CAN protocol interface and message buffer management submodules. This is the only bit in CANx_MCR not affected by soft reset. Refer to Section 21.4.6.2, “Module Disabled Mode,” for more information. 0 Enable the FlexCAN2 module 1 Disable the FlexCAN2 module
1 FRZ	Freeze enable. Specifies the FlexCAN2 behavior when the HALT bit in the CANx_MCR is set or when debug mode is requested at MCU level. When FRZ is asserted, FlexCAN2 is enabled to enter freeze mode. Negation of this bit field causes FlexCAN2 to exit from freeze mode. 0 Not enabled to enter freeze mode 1 Enabled to enter freeze mode
2	Reserved.
3 HALT	Halt FlexCAN. Assertion of this bit puts the FlexCAN2 module into freeze mode if FRZ is asserted. The CPU should clear it after initializing the message buffers and CANx_CR. If FRZ is set, no reception or transmission is performed by FlexCAN2 before this bit is cleared. While in freeze mode, the CPU has write access to the CANx_ECR, that is otherwise read-only. Freeze mode cannot be entered while FlexCAN2 is disabled. Refer to Section 21.4.6.1, “Freeze Mode,” for more information. 0 No freeze mode request. 1 Enters freeze mode if the FRZ bit is asserted.
4 NOTRDY	FlexCAN2 not ready. Indicates that FlexCAN2 is either disabled or in freeze mode. It is negated after FlexCAN2 has exited these modes. 0 FlexCAN2 module is either in normal mode, listen-only mode or loop-back mode 1 FlexCAN2 module is either disabled or freeze mode
5	Reserved.
6 SOFTRST	Soft reset. When asserted, FlexCAN2 resets its internal state machines and some of the memory-mapped registers. The following registers are affected by soft reset: <ul style="list-style-type: none"> • CANx_MCR (except the MDIS bit), • CANx_TIMER, • CANx_ECR, • CANx_ESR, • CANx_IMRL, • CANx_IMRH, • CANx_IFRL, • CANx_IFRH. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: <ul style="list-style-type: none"> • CANx_CR • CANx_RXGMASK • CANx_RX14MASK • CANx_RX15MASK • all Message buffers The SOFTRST bit can be asserted directly by the CPU when it writes to the CANx_MCR, but it is also asserted when global soft reset is requested at MCU level. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. 0 No reset request 1 Resets values in registers indicated above.

Table 21-7. CANx_MCR Field Descriptions (continued)

Field	Description
7 FRZACK	Freeze mode acknowledge. Indicates that FlexCAN2 is in freeze mode and its prescaler is stopped. The freeze mode request cannot be granted until current transmission and reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN2 has actually entered freeze mode. If freeze mode request is negated, then this bit is negated after the FlexCAN2 prescaler is running again. If freeze mode is requested while FlexCAN2 is disabled, then the FRZACK bit will only be set when the low power mode is exited. Refer to Section 21.4.6.1, “Freeze Mode,” for more information. 0 FlexCAN2 not in freeze mode, prescaler running 1 FlexCAN2 in freeze mode, prescaler stopped
8–9	Reserved.
10 WRNEN	Warning interrupt enable. When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register. If WRNEN is negated, the TWRNINT and RWRNINT flags will always be 0, independent of the values of the error counters, and no warning interrupt will ever be generated. 1 = TWRNINT and RWRNINT bits are set when the respective error counter transition from <96 to ≥ 96. 0 = TWRNINT and RWRNINT bits are zero, independent of the values in the error counters.
11 MDISACK	Low power mode acknowledge. Indicates whether FlexCAN2 is disabled. This cannot be performed until all current transmission and reception processes have finished, so the CPU can poll the MDISACK bit to know when FlexCAN2 has actually been disabled. Refer to Section 21.4.6.2, “Module Disabled Mode,” for more information. 0 FlexCAN2 not disabled 1 FlexCAN2 is disabled
12-13	Reserved.
14 SRXDIS	This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. 1 = Self reception disabled 0 = Self reception enabled
15 MBFEN	Message buffer filter enable. This bit provides the capability of enabling either individual masking of every message buffer, or global masking of message buffers. By negating MBFEN, the global masking capability is enabled in which FlexCAN uses the Rx ID masking scheme of RXGMASK, RX14MASK and RX15MASK. In this scheme, MB14 and MB15 have individual masks and the others share the global mask. The scheme does not provide a reception queue; i.e. a received message will always fill the first matching buffer, setting the CODE field to overrun if the buffer contained an unread message. Refer to Section 21.3.3.4, “RX Mask Registers” for more information. This global masking scheme is compatible with previous FlexCAN versions and at reset MBFEN is negated so that existing software retains compatibility. By asserting MBFEN, individual Rx ID masking and the reception queue features are enabled. In this scheme, individual receive mask registers (RXIM[0-63]) are provided for each MB. Upon receiving a message, FlexCAN will look in the reception queue for the first empty matching MB. Refer to Section 21.3.3.5, “RX Individual Mask Registers (CANx_RXIMR0 – CANx_RXIMR63)” and Section 21.4.3.2, “Reception Queue” for more information. 0 Individual RX masking and reception queue features are disabled (thus the device is compatible with previous FlexCAN versions, i.e. one global mask register is used). 1 Individual RX masking and reception queue features are enabled.

Table 21-7. CANx_MCR Field Descriptions (continued)

Field	Description
16-25	Reserved.
26-31 MAXMB[0:5]	<p>Maximum number of message buffers. This 6-bit field defines the maximum number of message buffers of the FlexCAN2 module. The reset value (0x0F) is equivalent to 16 MB configuration. This field should be changed only while the module is in freeze mode.</p> <p style="text-align: center;">Maximum MBs in use = MAXMB + 1</p> <p>Note: MAXMB has to be programmed with a value smaller or equal to the number of available message buffers, otherwise FlexCAN2 will not transmit or receive frames.</p>

21.3.3.2 Control Register (CANx_CR)

CANx_CR is defined for specific FlexCAN2 control features related to the CAN bus, such as bit-rate, programmable sampling point within an RX bit, loop-back mode, listen-only mode, bus off recovery behavior, and interrupt enabling (for example, bus-off, error). It also determines the division factor for the clock prescaler. BOFFMSK, ERRMSK, and BOFFREC bits can be accessed at any time. CANx_CR is unaffected by soft reset, which occurs when CAN_MCR[SOFTTRST] is asserted.

Address: Base + 0x0004

Access: User read/write

¹ CANx_CR is unaffected by soft reset (which occurs when CAN_MCR[SOFTTRST] is asserted).

Figure 21-4. Control Register (CANx_CR)

Table 21-8. CANx_CR Field Descriptions

Bits	Description
0-7 PRESDIV[0:7]	<p>Prescaler division factor. Defines the ratio between the CPI clock frequency and the serial clock (SCK) frequency. The SCK period defines the time quantum of the CAN protocol. For the reset value, the SCK frequency is equal to the CPI clock frequency. The maximum value of this register is 0xFF, that gives a minimum SCK frequency equal to the CPI clock frequency divided by 256. For more information, refer to Section 21.4.5.4, "Protocol Timing."</p> $\text{S-clock frequency} = \frac{\text{CPI clock frequency}}{\text{PRESDIV} + 1}$
8-9 RJW[0:1]	<p>Resync jump width. Defines the maximum number of time quanta¹ that a bit time can be changed by one re-synchronization. The valid programmable values are 0-3.</p> $\text{Resync Jump Width} = \text{RJW} + 1$

Table 21-8. CANx_CR Field Descriptions

Bits	Description
10–12 PSEG1[0:2]	Phase segment 1. Defines the length of phase buffer segment 1 in the bit time. The valid programmable values are 0–7. Phase Buffer Segment 1 = (PSEG1 + 1) × Time Quanta
13–15 PSEG2[0:2]	Phase segment 2. Defines the length of phase buffer segment 2 in the bit time. The valid programmable values are 1–7. Phase Buffer Segment 2 = (PSEG2 + 1) × Time Quanta
16 BOFFMSK	Bus off mask. Provides a mask for the bus off interrupt. 0 Bus off interrupt disabled 1 Bus off interrupt enabled
17 ERRMSK	Error mask. Provides a mask for the error interrupt. 0 Error interrupt disabled 1 Error interrupt enabled
18 CLK_SRC	CAN engine clock source. Selects the clock source to the CAN Protocol Interface (CPI) to be either the system clock (driven by the PLL) or the crystal oscillator clock. The selected clock is fed into the prescaler to generate the serial clock (SCK). 0 = The CAN engine clock source is the oscillator clock 1 = The CAN engine clock source is the system clock
19 LPB	Loop back. Configures FlexCAN2 to operate in loop-back mode. Refer to Section 21.1.4, “Modes of Operation” for information about this operating mode. 0 Loop back disabled 1 Loop back enabled
20 TWRNMSK	This bit provides a mask for the TX Warning Interrupt associated with the TWRNINT flag in the Error and Status Register. This bit has no effect if the WRNEN bit in CANx_MCR is negated and it is read as zero when WRNEN is negated. 1 = Tx Warning Interrupt enabled 0 = Tx Warning Interrupt disabled
21 RWRNMSK	This bit provides a mask for the RX Warning Interrupt associated with the RWRNINT flag in the Error and Status Register. This bit has no effect if the WRNEN bit in CANx_MCR is negated and it is read as zero when WRNEN is negated. 1 = Rx Warning Interrupt enabled 0 = Rx Warning Interrupt disabled
22–23	Reserved.
24 SMP	Sampling mode. Defines the sampling mode of each bit in the receiving messages (RX). 0 Just one sample is used to determine the RX bit value 1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples, a majority rule is used

Table 21-8. CANx_CR Field Descriptions

Bits	Description
25 BOFFREC	<p>Bus off recovery mode. Defines how FlexCAN2 recovers from bus off state. If this bit is negated, automatic recovering from bus off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from bus off is disabled and the module remains in bus off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then bus off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN2 will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during bus off, but it will only be effective the next time the module enters bus off. If BOFFREC was negated when the module entered bus off, asserting it during bus off will not be effective for the current bus off recovery.</p> <p>0 Automatic recovering from bus off state enabled, according to CAN Spec 2.0 part B 1 Automatic recovering from bus off state disabled</p>
26 TSYN	<p>Timer sync mode. Enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides means to synchronize multiple FlexCAN2 stations with a special SYNC message (that is, global network time).</p> <p>0 Timer sync feature disabled 1 Timer sync feature enabled</p> <p>Note: There is a possibility of 4–5 ticks count skew between the different FlexCAN2 stations that would operate in this mode.</p>
27 LBUF	<p>Lowest buffer transmitted first. This bit defines the ordering mechanism for message buffer transmission.</p> <p>0 Buffer with lowest ID is transmitted first 1 Lowest number buffer is transmitted first</p>
28 LOM	<p>Listen-only mode. Configures FlexCAN2 to operate in listen-only mode. In this mode, the FlexCAN2 module receives messages without giving any acknowledge. It is not possible to transmit any message in this mode.</p> <p>0 FlexCAN2 module is in normal active operation, listen only mode is deactivated 1 FlexCAN2 module is in listen only mode operation</p>
29–31 PROPSEG [0:2]	<p>Propagation segment. Defines the length of the propagation segment in the bit time. The valid programmable values are 0–7.</p> $\text{Propagation Segment Time} = (\text{PROPSEG} + 1) \times \text{Time Quanta}$ <p style="text-align: center;">Time Quantum = one S clock period</p>

¹ One time quantum is equal to the S clock period.

21.3.3.3 Free Running Timer (CANx_TIMER)

CANx_TIMER represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0000 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is clocked by the FlexCAN2 bit-clock (which defines the baud rate on the CAN bus). During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. During freeze mode, the timer is not incremented.

The timer value is captured at the beginning of the identifier field of any frame on the CAN bus. This captured value is written into the TIME STAMP entry in a message buffer after a successful reception or transmission of a message.

Writing to the timer is an indirect operation. The data is first written to an auxiliary register and then an internal request/acknowledge procedure across clock domains is executed. All this is transparent to the user, except for the fact that the data will take some time to be actually written to the register. If desired, software can poll the register to discover when the data was actually written.

Figure 21-5. Free Running Timer (CAN_x_TIMER)

21.3.3.4 RX Mask Registers

By negating the CAN_x_MCR[MBFEN] bit, the CAN_x_RXGMASK, CAN_x_RX14MASK, and CAN_x_RX15MASK registers are used as acceptance masks for received frame IDs. Three masks are defined: a global mask, used for RX buffers 0–13 and 16–63, and two extra masks dedicated for buffers 14 and 15. The meaning of each mask bit is the following:

- Mask bit = 0: the corresponding incoming ID bit is “don’t care.”
- Mask bit = 1: the corresponding ID bit is checked against the incoming ID bit, to see if a match exists.

Note that these masks are used both for standard and extended ID formats. The value of mask registers should not be changed while in normal operation. Locked frames which had matched a MB through a mask may be transferred into the MB (upon release) but may no longer match. Table 21-9 shows some examples of ID masking for standard and extended message buffers.

Table 21-9. Mask Examples for Standard/Extended Message Buffers

	Base ID ID28.....ID18	IDE	Extended ID ID17.....ID0	Match

21.3.3.4.1 RX Global Mask (CANx_RXGMASK)

The RX global mask bits are applied to all RX identifiers excluding RX buffers 14–15, that have their specific RX mask registers. Access to this register is unrestricted. Note that CANx_RXGMASK is unaffected by soft reset (which occurs when CAN_MCR[SOFTTRST] is asserted).

Address: Base + 0x0010 (CANx_RXGMASK) Access: User read/write
 Base + 0x0014 (CANx_RX14MASK)
 Base + 0x0018 (CANx_RX15MASK)

¹ CANx_RXGMASK is unaffected by soft reset (which occurs when CAN_MCR[SOFTTRST] is asserted).

Figure 21-6. RX Global Mask Register (CANx_RXGMASK)

Table 21-10. CANx_RXGMASK Field Descriptions

Field	Description
0–2	Reserved, should be cleared.
3–13 MI n	Standard ID mask bits. These bits are the same mask bits for the standard and extended formats.
14–31 MI n	Extended ID mask bits. These bits are used to mask comparison only in extended format.

21.3.3.4.2 RX 14 Mask (CANx_RX14MASK)

The CANx_RX14MASK register has the same structure as the RX global mask register and is used to mask message buffer 14. Access to this register is unrestricted. Note that CANx_RX14MASK is unaffected by soft reset (which occurs when CAN_MCR[SOFTRST] is asserted).

- Address offset: 0x14
- Reset value: 0x1FFF_FFFF

21.3.3.4.3 RX 15 Mask (CANx_RX15MASK)

The CANx_RX15MASK register has the same structure as the RX global mask register and is used to mask message buffer 15. Access to this register is unrestricted. Note that CANx_RX15MASK is unaffected by soft reset (which occurs when CAN_MCR[SOFTRST] is asserted).

- Address offset: 0x18
- Reset value: 0x1FFF_FFFF

21.3.3.5 RX Individual Mask Registers (CANx_RXIMR0 – CANx_RXIMR63)

By asserting the CANx_MCR[MBFEN] bit, the CANx_RXIMR[0-63] registers are used as acceptance masks for received frame IDs, in both standard and extended ID formats. One mask register is provided for each message buffer for individual ID masking per message buffer. The meaning of each mask bit is the following:

- Mask bit = 0: The corresponding incoming ID bit is a “don’t care.”
- Mask bit = 1: The corresponding ID bit is checked against the incoming ID bit, to see if a match exists.

The Individual Rx Mask Registers are implemented in RAM, so they are not affected by reset and must be explicitly initialized prior to any reception. Furthermore, they can only be accessed by the CPU while the module is in freeze mode. Out of freeze mode, write accesses are blocked and read accesses will return all 0s. Furthermore, if the MBFEN bit in the MCR register is negated, any read or write operation to these RXIMR_n registers results in access error.

21.3.3.6 Error Counter Register (CANx_ECR)

CANx_ECR has two 8-bit fields reflecting the value of two FlexCAN2 error counters: the transmit error counter (TXECTR field) and receive error counter (RXECTR field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN2 module. Both counters are read only except in freeze mode, where they can be written by the CPU.

Writing to the CANx_ECR while in freeze mode is an indirect operation. The data is first written to an auxiliary register and then an internal request/acknowledge procedure across clock domains is executed. All this is transparent to the user, except for the fact that the data will take some time to be actually written to the register. If desired, software can poll the register to discover when the data was actually written.

FlexCAN2 responds to any bus state as described in the protocol: transmitting, for example, an ‘error active’ or ‘error passive’ flag, delaying its transmission start time (‘error passive’), and avoiding any influence on the bus when in the bus off state. The following are the basic rules for FlexCAN2 bus state transitions:

- If the value of TXECTR or RXECTR increases to be greater than or equal to 128, the FLTCONF field in the CANx_ESR is updated to reflect the ‘error passive’ state.
- If the FlexCAN2 state is ‘error passive,’ and either TXECTR or RXECTR decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the CANx_ESR is updated to reflect the ‘error active’ state.
- If the value of TXECTR increases to be greater than 255, the FLTCONF field in the CANx_ESR is updated to reflect the bus off state, and an interrupt may be issued. The value of TXECTR is then reset to zero.
- If FlexCAN2 is in the bus off state, then TXECTR is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXECTR is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXECTR. When TXECTR reaches the value of 128, the FLTCONF field in CANx_ESR is updated to be ‘error active’ and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXECTR value.
- If during system start-up, only one node is operating, then its TXECTR increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in CANx_ESR). After the transition to the ‘error passive’ state, the TXECTR does not increment anymore by acknowledge errors. Therefore the device never goes to the bus off state.

- If the RXECTR increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to ‘error active’ state.

Figure 21-8. Error Counter Register (CANx_ECR)

21.3.3.7 Error and Status Register (CANx_ESR)

CANx_ESR reflects various error conditions, some general status of the device, and it is the source of two interrupts to the CPU. The reported error conditions (bits 16–21) are those that occurred since the last time the CPU read this register. The CPU read action clears BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, and STFERR. TXWRN, RXWRN, IDLE, TXRX, FLTCONF, BOFFINT, and ERRINT are status bits.

Most bits in this register are read-only, except BOFFINT, ERRINT, TWRNINT, and RWRNINT which are interrupt flags that can be cleared by writing 1 to them (writing 0 has no effect).

Refer to [Section 21.4.7, “Interrupts,”](#) for more details.

NOTE

A read clears BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, and STFERR, therefore these bits must not be read speculatively. For future compatibility, the TLB entry covering the CANx_ESR must be configured to be guarded.

Figure 21-9. Error and Status Register (CANx_ESR)

Table 21-12. CANx_ESR Field Descriptions

Field	Description
0–13	Reserved.
14 TWRNINT	If the WRNEN bit in CANx_MCR is asserted, the TWRNINT bit is set when the TXWRN flag transitions from 0 to 1, meaning that the TX error counter reached 96. If the corresponding mask bit in the Control Register (TWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing to 1. Writing 0 has no effect. 0 No such occurrence 1 TXECTR ≥ 96
15 RWRNINT	If the WRNEN bit in CANx_MCR is asserted, the RWRNINT bit is set when the RXWRN flag transitions from 0 to 1, meaning that the RX error counter reached 96. If the corresponding mask bit in the Control Register (RWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing to 1. Writing 0 has no effect. 0 No such occurrence 1 RXECTR ≥ 96
16 BIT1ERR	Bit 1 error. Indicates when an inconsistency occurs between the transmitted and the received message in a bit. A read clears BIT1ERR. 0 No such occurrence 1 At least one bit sent as recessive is received as dominant Note: This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.
17 BIT0ERR	Bit 0 error. Indicates when an inconsistency occurs between the transmitted and the received message in a bit. A read clears BIT0ERR. 0 No such occurrence 1 At least one bit sent as dominant is received as recessive
18 ACKERR	Acknowledge error. Indicates that an acknowledge error has been detected by the transmitter node; that is, a dominant bit has not been detected during the ACK SLOT. A read clears ACKERR. 0 No such occurrence 1 An ACK error occurred since last read of this register
19 CRCERR	Cyclic redundancy code error. Indicates that a CRC error has been detected by the receiver node; that is, the calculated CRC is different from the received. A read clears CRCERR. 0 No such occurrence 1 A CRC error occurred since last read of this register.
20 FRMERR	Form error. Indicates that a form error has been detected by the receiver node; that is, a fixed-form bit field contains at least one illegal bit. A read clears FRMERR. 0 No such occurrence 1 A form error occurred since last read of this register
21 STFERR	Stuffing error. Indicates that a stuffing error has been detected. A read clears STFERR. 0 No such occurrence. 1 A stuffing error occurred since last read of this register.
22 TXWRN	TX error counter. This status bit indicates that repetitive errors are occurring during message transmission. 0 No such occurrence 1 TXECTR ≥ 96
23 RXWRN	RX error counter. This status bit indicates when repetitive errors are occurring during messages reception. 0 No such occurrence 1 RXECTR ≥ 96

Table 21-12. CANx_ESR Field Descriptions (continued)

Field	Description
24 IDLE	CAN bus IDLE state. This status bit indicates when CAN bus is in IDLE state. 0 No such occurrence 1 CAN bus is now IDLE
25 TXRX	Current FlexCAN2 status (transmitting/receiving). This status bit indicates if FlexCAN2 is transmitting or receiving a message when the CAN bus is not in IDLE state. This bit has no meaning when IDLE is asserted. 0 FlexCAN2 is receiving a message (IDLE = 0) 1 FlexCAN2 is transmitting a message (IDLE = 0)
26–27 FLTCONF[0:1]	Fault confinement state. This status bit indicates the confinement state of the FlexCAN2 module. If the LOM bit in the CANx_CR is asserted, the FLTCONF field will indicate “Error Passive”. Since the CANx_CR is not affected by soft reset, the FLTCONF field will not be affected by soft reset if the LOM bit is asserted. 00 Error active 01 Error passive 1X Bus off
28	Reserved.
29 BOFFINT	Bus off interrupt. This status bit is set when FlexCAN2 is in the bus off state. If CANx_CR[BOFFMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence 1 FlexCAN2 module is in ‘Bus Off’ state
30 ERRINT	Error interrupt. This status bit indicates that at least one of the error bits (bits 16-21) is set. If CANx_CR[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence 1 Indicates setting of any error bit in the CANx_ESR
31	Reserved.

21.3.3.8 Interrupt Masks High Register (ICANx_IMRH)

CANx_IMRH allows any number of a range of 32 message buffer interrupts to be enabled or disabled. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception (that is, when the corresponding IFRH bit is set).

Field	Description
0–31 BUF n	Message buffer n interrupt. Each bit represents the respective FlexCAN2 message buffer (MB31 to MB0) interrupt. Write 1 to clear. 0 No such occurrence 1 The corresponding buffer has successfully completed transmission or reception.

21.4 Functional Description

21.4.1 Overview

The FlexCAN2 module is a CAN protocol engine with a very flexible message buffer configuration scheme. The module can have up to 64 message buffers, any of which can be assigned as either a TX buffer or an RX buffer. Each message buffer has an assigned interrupt flag to indicate successful completion of transmission or reception.

21.4.2 Transmit Process

The CPU prepares a message buffer for transmission by executing the following steps:

- Write the CODE field of the control and status word to keep the TX MB inactive (code = 1000).
- Write the ID word.
- Write the DATA bytes.
- Write the LENGTH, SRR, IDE, RTR, and CODE fields of the control and status word to activate the TX MB.

The first and last steps are mandatory.

21.4.2.1 Arbitration Process

This process selects which will be the next MB to be transmitted. All MBs programmed as transmit buffers will be scanned to find the lowest ID¹ or the lowest MB number, depending on the LBUF bit in the CAN x _CR. The selected MB will be transferred to an internal serial message buffer (SMB), which is not user accessible, and then transmitted.

1. Actually, if LBUF is negated, the arbitration considers not only the ID, but also the RTR and IDE bits placed inside the ID at the same positions they are transmitted in the CAN frame.

The arbitration process is triggered in the following events:

- During the CRC field of the CAN frame
- During the error delimiter field of the CAN frame
- During Intermission, if the winner MB defined in a previous arbitration was deactivated, or if there was no MB to transmit, but the CPU wrote to the C/S word of any MB after the previous arbitration finished.
- When MBM is in idle or bus off state and the CPU writes to the C/S word of any MB
- Upon leaving freeze mode

When the arbitration is over, and there is a winner MB for transmission, the frame is transferred to the SMB for transmission. This is called ‘move out.’ After move out, the CAN transmit machine will start to transmit the frame according to the CAN protocol rules. FlexCAN2 transmits up to eight data bytes, even if the data length code (DLC) value is bigger.

At the end of a successful transmission, the value of the free running timer at the beginning of the identifier field is written into the TIME STAMP field in the MB, the CODE field in the control and status word of the MB is updated, a status flag is set in CAN_x_IFRL or CAN_x_IFRH, and an MB interrupt is generated if allowed by the corresponding interrupt mask register bit.

21.4.3 Receive Process

The CPU prepares a message buffer for frame reception by executing the following steps:

- Write the CODE field of the control and status word to keep the RX MB as INACTIVE (CODE = 0000).
- Write the ID word.
- Write the CODE field of the control and status word to mark the MB as EMPTY.

The first and last steps are mandatory.

21.4.3.1 Matching Process

The matching process compares the IDs of all active RX message buffers to newly received frames, so that, if a match occurs, a newly received frame is transferred (moved in) to the first (that is, lowest entry) matching MB when the reception queue feature is disabled. Only MBs marked as EMPTY, FULL, or OVERRUN will participate in the internal matching process at the CRC frame field. The internal matching process takes place every time the receiver receives an error free frame.

The value of the free running timer is written into the TIME STAMP field in the MB. The ID field, the DATA field (8 bytes at most), and the LENGTH field are stored, the CODE field is updated, and a status flag is set in CAN_x_IFRL or CAN_x_IFRH, and an interrupt is generated if the corresponding interrupt mask is enabled in CAN_x_IMRL/H.

The CPU should read an RX frame from its MB in the following way:

- Control and status word (mandatory, activates internal lock for this buffer)
- ID (optional, needed only if a mask was used)
- DATA field words
- Free running timer (optional, releases internal lock)

Reading the free running timer is not mandatory. If not executed, the MB remains locked, unless the CPU starts reading another MB. Note that only a single MB is locked at a time. The only mandatory CPU read operation is of the control and status word, to assure data coherency. If the BUSY bit is set in the CODE field, then the CPU should defer the access to the MB until this bit is negated.

The CPU should synchronize to frame reception by the status flag bit for the specific MB in one of the CANx_IFRH and CANx_IFRL registers and not by the control and status word code field of that MB. Polling the CODE field does not work because after a frame was received and the CPU services the MB (by reading the C/S word followed by unlocking the MB), the CODE field will not return to EMPTY. It will remain FULL, as explained in [Table 21-5](#). If the CPU tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the MB, the MB is actually deactivated from any currently ongoing matching process. As a result, a newly received frame matching the ID of that MB may be lost. In summary: never do polling by reading directly the C/S word of the MBs. Instead, read the CANx_IFRH and CANx_IFRL registers.

Note that the received ID field is always stored in the matching MB, thus the contents of the ID field in a MB can change if the match was due to mask.

21.4.3.2 Reception Queue

A queue of received messages can be implemented that allows the CPU more time for servicing MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. Matching to a range of IDs is possible by using ID acceptance masks that mask individual MBs. During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a don't care.

Suppose, for example, that the second and fifth MBs in an array have the same ID, and FlexCAN starts receiving messages with that ID. When FlexCAN receives the first message, the matching algorithm matches it to MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not free to receive¹, so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm perceives that there are no matching MBs that are free to receive so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the Code field of the MB to indicate OVERRUN.

In this manner, a reception queue is built, with messages temporally ordered by the CPU's reading of each MB's time stamp field. This functionality is set by asserting the CANx_MCR[MBFEN] bit. Note that the RXIMR_n registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed if the MBFEN bit is asserted and while the module is in freeze mode.

1. If, however, the CPU has read the MB2 data and released it before the next matching process at the CRC frame, then, even if the MB2 RX code is FULL, the MB2 is free to receive and the message will be stored in MB2 rather than in MB5.

FlexCAN also supports an alternate masking scheme with only three mask registers (`CANx_RXGMASK`, `CANx_RX14MASK`, and `CANx_RX15MASK`) for backwards compatibility. This alternate masking scheme is enabled when `CANx_MCR[MBFEN]` is negated.

Refer to [Section 21.3.3.4, “RX Mask Registers.”](#)

21.4.3.3 Self Received Frames

FlexCAN2 receives frames transmitted by itself if there exists an RX matching MB, but only if an ACK is generated by an external node or if loop-back mode is enabled. Note also that FlexCAN does receive frames transmitted by itself if there exists an RX matching MB, provided the `MCR[SRXDIS]` bit is not asserted. If `SRXDIS` is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

21.4.4 Message Buffer Handling

To maintain data coherency and FlexCAN2 proper operation, the CPU must obey the rules described in [Section 21.4.2, “Transmit Process,”](#) and [Section 21.4.3, “Receive Process.”](#) Any form of CPU accessing a MB structure within FlexCAN2 other than those specified can cause FlexCAN2 to behave in an unpredictable way.

Deactivation of a message buffer is a CPU action that causes that MB to be excluded from FlexCAN2 transmit or receive processes during the current match/arbitration round. Any CPU write access to a control and status word of the MB structure deactivates that MB, excluding it from the current RX/TX process. However, deactivation is not permanent. The MB that was deactivated during the current match/arbitration round will be available for transmission or reception in the next round.

The purpose of deactivation is data coherency. The match/arbitration process scans the MBs to decide which MB to transmit or receive. If the CPU updates the MB in the middle of a match or arbitration process, the data of that MB may no longer be coherent, therefore that MB is deactivated.

Match and arbitration are one-pass processes. After scanning all MBs, a winner is determined. If MBs are changed after they are scanned, no re-evaluation is done to determine a new match/winner; and a frame may be lost because the matched MB may have been deactivated. If two RX MBs have a matching ID to a received frame, then it is not guaranteed reception if the user deactivated the matching MB after FlexCAN2 has scanned the second.

21.4.4.1 Notes on TX Message Buffer Deactivation

There is a point in time until which the deactivation of a TX MB causes it not to be transmitted (end of move out). After this point, it is transmitted but no interrupt is issued and the `CODE` field is not updated.

If a TX MB containing the lowest ID (or lowest buffer if `LBUF` is set) is deactivated after FlexCAN2 has scanned it while in arbitration process, then FlexCAN2 can transmit a MB with ID that may not be the lowest at the time.

21.4.4.2 Notes on RX Message Buffer Deactivation

If the deactivation occurs during move in, the move operation is aborted and no interrupt is issued, but the MB contains mixed data from two different frames.

In case the CPU writes data into RX MB data words while it is being moved in, the move operation is aborted and no interrupt will be issued, but the control/status word may be changed to reflect FULL or OVRN. This action should be avoided.

21.4.4.3 Data Coherency Mechanisms

The FlexCAN2 module has a mechanism to assure data coherency in both receive and transmit processes. The mechanism includes a lock status for MBs and two internal storage areas, called serial message buffers (SMB), to buffer frame transfers within FlexCAN. The details of the mechanism are the following:

- CPU reading a control and status word of an MB triggers a lock for that MB; that is, a new RX frame which matches this MB, cannot be written into this MB.
- To release a locked MB, the CPU should either lock another MB (by reading its control and status word), or globally release any locked MB (by reading the free-running timer).
- If the CPU reads a RX MB while it is being transferred into (from) SMB, then the BUSY bit is set in the CODE field of the control and status word. To assure data coherency, the CPU should wait until this BUSY bit is negated before further reading from that MB. Note that in this case such MB is not locked.
- If the CPU deactivates a locked RX MB, then its lock status is negated, but no data is transferred into that MB.

The following bullets apply only if: the reception queue is disabled, if there are no other matching buffers in the reception queue, or for the last available queue element when all others are not free to receive (the last queue element will be overwritten in the same manner described here for a single MB in non-queue mode). If the reception queue is enabled, the state machine searches for the next matching message buffer.

- If while a MB is locked, an RX frame with a matching ID is received, then it cannot be stored within that MB and it remains in the SMB. There is no indication in the CAN_x_ESR of that situation.
- If while a MB is locked, two or more RX frames with matching ID are received, then the last received one is kept within the SMB, while all preceding ones are lost. There is no indication that the preceding ones were lost in the CAN_x_ESR.
- If a locked MB is released, and there exists a matching frame within the SMB, this frame is then transferred to the matching MB.

21.4.5 CAN Protocol Related Features

21.4.5.1 Remote Frames

A remote frame is a special kind of frame. The user can program a MB to be a request remote frame by writing the MB as transmit with the RTR bit set to 1. After the remote request frame is transmitted successfully, the MB becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, its ID is compared to the IDs of the transmit message buffers with the CODE field '1010'. If there is a matching ID, then this MB frame will be transmitted. Note that if the matching MB has the RTR bit set, then FlexCAN2 will transmit a remote frame as a response.

A received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match.

In the case that a remote request frame was received and matched a MB, this message buffer immediately enters the internal arbitration process, but is considered as normal TX MB, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

21.4.5.2 Overload Frames

FlexCAN2 will transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of intermission
- Detection of a dominant bit at the 7th bit (last) of end of frame field (RX frames)
- Detection of a dominant bit at the 8th bit (last) of error frame delimiter or overload frame delimiter

21.4.5.3 Time Stamp

The value of the free running timer is sampled at the beginning of the identifier field on the CAN bus, and is stored at the end of 'move in' in the TIME STAMP field, providing network behavior with respect to time.

The free running timer can be reset upon a specific frame reception, enabling network time synchronization. Refer to TSYN description in [Section 21.3.3.2, "Control Register \(CANx_CR\)."](#)

21.4.5.4 Protocol Timing

The clock source to the CAN protocol interface (CPI) can be either the system clock or a direct feed from the oscillator pin EXTAL. The clock source is selected by the CLK_SRC bit in the CAN_CR. The clock is fed to the prescaler to generate the serial clock (SCK).

The FlexCAN2 module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The CANx_CR has various fields used to control bit timing parameters: PRES DIV, PROPSEG, PSEG1, PSEG2 and RJW. Refer to [Section 21.3.3.2, "Control Register \(CANx_CR\)."](#)

The PRESDIV field controls a prescaler that generates the serial clock (SCK), whose period defines the ‘time quantum’ used to compose the CAN waveform. A time quantum is the atomic unit of time handled by FlexCAN.

$$f_{Tq} = \frac{f_{CANCLK}}{\text{Prescaler Value}}$$

A bit time is subdivided into three segments¹ (reference [Figure 21-14](#) and [Table 21-17](#)):

- SYNCSEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.
- Time segment 1: This segment includes the propagation segment and the phase segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL register so that their sum (plus 2) is in the range of 4 to 16 time quanta.
- Time segment 2: This segment represents the phase segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL register (plus 1) to be 2 to 8 time quanta long.

$$\text{Bit rate} = \frac{f_{Tq}}{\text{(Number of Time Quanta)}}$$

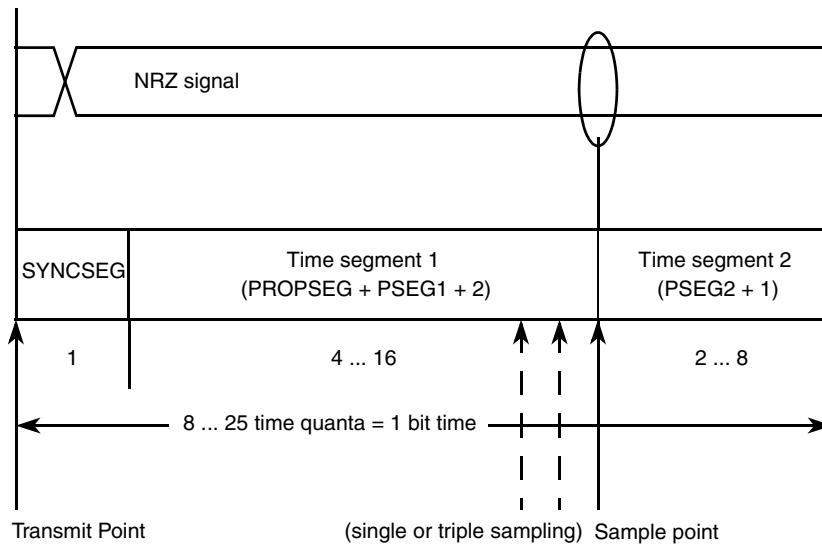

Figure 21-14. Segments within the Bit Time

1. For further explanation of the underlying concepts please refer to ISO/DIS 11519–1, Section 10.3. Reference also the Bosch CAN 2.0A/B protocol specification dated September 1991 for bit timing.

Table 21-17 describes the time segment syntax:

Table 21-17. Time Segment Syntax

Syntax	Description
SYNCSEG	System expects transitions to occur on the bus during this period.
Transmit point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample point	A node in receive mode samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

Table 21-18 gives an overview of the CAN compliant segment settings and the related parameter values.

NOTE

Ensure the bit time settings are in compliance with the CAN standard.

Table 21-18. CAN Standard Compliant Bit Time Segment Settings

Time Segment 1	Time Segment 2	Resynchronization Jump Width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

21.4.5.5 Arbitration and Matching Timing

During normal transmission or reception of frames, the arbitration, match, move in and move out processes are executed during certain time windows inside the CAN frame, as shown in Figure 21-15. When doing matching and arbitration, FlexCAN2 needs to scan the whole message buffer memory during the available time slot. To have sufficient time to do that, the following restrictions must be observed:

- A valid CAN bit timing must be programmed, as indicated in Figure 21-15.
- The system clock frequency cannot be smaller than the oscillator clock frequency, i.e. the PLL cannot be programmed to divide down the oscillator clock.
- There must be a minimum ratio of 16 between the system clock frequency and the CAN bit rate.

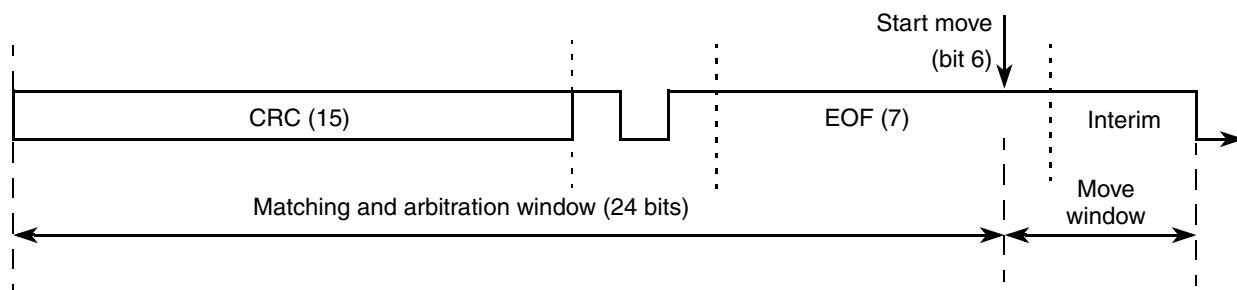

Figure 21-15. Arbitration, Match and Move Time Windows

21.4.6 Modes of Operation Details

21.4.6.1 Freeze Mode

This mode is entered by asserting the HALT bit in the CAN_x_MCR or when the MCU is put into debug mode. In both cases it is also necessary that the FRZ bit is asserted in the CAN_x_MCR. When freeze mode is requested during transmission or reception, FlexCAN2 does the following:

- Waits to be in either intermission, passive error, bus off or idle state
- Waits for all internal activities like move in or move out to finish
- Ignores the RX input pin and drives the TX pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the CAN_x_ECR, which is read-only in other modes
- Sets the NOTRDY and FRZACK bits in CAN_x_MCR

After requesting freeze mode, the user must wait for the FRZACK bit to be asserted in CAN_x_MCR before executing any other action, otherwise FlexCAN2 can operate in an unpredictable way. In freeze mode, all memory mapped registers are accessible; CAN_x_RXIMR_n registers can be programmed only if the MBFEN bit is asserted.

Exiting freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the CAN_x_MCR.
- The MCU exits debug mode and/or the HALT bit is negated.

After it is out of freeze mode, FlexCAN2 tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

21.4.6.2 Module Disabled Mode

This low power mode is entered when the CAN_x_MCR[MDIS] bit is asserted. If the module is disabled during freeze mode, it shuts down the clocks to the CPI and MBM sub-modules, sets the CAN_x_MCR[MDISACK] bit and negates the CAN_x_MCR[FRZACK] bit.

If the module is disabled during transmission or reception, FlexCAN2 does the following:

- Waits to be in either idle or bus off state, or else waits for the third bit of intermission and then checks it to be recessive
- Waits for all internal activities like move in or move out to finish
- Ignores its RX input pin and drives its TX pin as recessive
- Shuts down the clocks to the CPI and MBM sub-modules
- Sets the NOTRDY and MDISACK bits in CAN_x_MCR

The bus interface unit continues to operate, enabling the CPU to access memory mapped registers except the free running timer, the CAN_x_ECR and the message buffers, which cannot be accessed when the module is disabled. Exiting from this mode is done by negating the CAN_x_MCR[MDIS] bit, which will resume the clocks and negate the CAN_x_MCR[MDISACK] bit.

21.4.7 Interrupts

The module can generate interrupts from 20 interrupt sources (16 interrupts due to message buffers, one interrupt due to an error condition, two interrupts for the OR'd MB16–MB31 and MB32–63, and one interrupt for one of the following: a bus off condition, a transmit warning, or a receive warning).

Each of the 64 message buffers can be an interrupt source, if its corresponding CAN_x_IMRH or CAN_x_IMRL bit is set. There is no distinction between TX and RX interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the CAN_x_IFRH or CAN_x_IFRL registers. The bit is set when the corresponding buffer completes a successful transmission/reception and is cleared when the CPU writes it to 1.

A combined interrupt for each of two MB groups, MB16–MB31 and MB32–MB63, is also generated by an OR of all the interrupt sources from the associated MBs. This interrupt gets generated when any of the MBs generates an interrupt. In this case the CPU must read the CAN_x_IFRH and CAN_x_IFRL registers to determine which MB caused the interrupt.

The other two interrupt sources (bus off/transmit warning/receive warning and error) generate interrupts like the MB interrupt sources, and can be read from CAN_x_ESR. The bus off/transmit warning/receive warning and error interrupt mask bits are located in the CAN_x_CR.

21.4.8 Bus Interface

The CPU access to FlexCAN2 registers are subject to the following rules:

- Read and write access to unimplemented or reserved address space also results in access error. Any access to unimplemented MB locations results in access error.
- For a FlexCAN2 configuration that uses less than the total number of MBs and MAXMB is set accordingly, the remaining MB and RX mask register spaces can be used as general-purpose RAM space. Byte, word and long word accesses are allowed to the unused MB space.

NOTE

Unused MB space must not be used as general purpose RAM while FlexCAN is transmitting and receiving CAN frames.

21.5 Initialization and Application Information

This section provides instructions for initializing the FlexCAN2 module.

21.5.1 FlexCAN2 Initialization Sequence

The FlexCAN2 module can be reset in three ways:

- MCU-level hard reset, which resets all memory mapped registers asynchronously
- MCU-level soft reset, which resets some of the memory mapped registers synchronously (refer to [Table 21-2](#) for the registers affected by a soft reset)
- SOFTRST bit in CAN_x_MCR, which has the same effect as the MCU level soft reset

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFTRST bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed.

After the module is enabled (CAN_x_MCR[MDIS] bit negated), FlexCAN2 should be put into freeze mode before doing any configuration. In freeze mode, FlexCAN2 is un-synchronized to the CAN bus, the HALT and FRZ bits in CAN_x_MCR are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the CAN_x_MCR are set. The CNTX pin is in recessive state and FlexCAN2 does not initiate frame transmission nor receives any frames from the CAN bus. Note that the message buffer contents are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization, it is required that FlexCAN2 is put into freeze mode (refer to [Section 21.4.6.1, “Freeze Mode](#)). The following is a generic initialization sequence applicable for the FlexCAN2 module:

- Initialize CAN_x_CR.
 - Determine bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW.
 - Determine the bit rate by programming the PRES DIV field.
 - Determine internal arbitration mode (LBUF bit).
- Initialize message buffers.
 - The control and status word of all message buffers may be written either as active or inactive.
 - Other entries in each message buffer should be initialized as required.
- Initialize CAN_x_MCR bits MBFEN, SRXDIS, and WRNEN.
- The initialization of FlexCAN registers for either global or individual acceptance masking depends on the configuration of MBFEN:
 - If MBFEN is negated, initialize CAN_x_RXGMASK, CAN_x_RX14MASK, and CAN_x_RX15MASK registers for acceptance mask.
 - If MBFEN is asserted, initialize CAN_x_RXIMR[0-63] for individual acceptance masking.
- Set required mask bits in CAN_x_IMRH and CAN_x_IMRL registers (for all MBs interrupts), and in CAN_x_CR (for bus off and error interrupts).
- Negate the CAN_x_MCR[HALT] bit.

Starting with this last event, FlexCAN2 attempts to synchronize with the CAN bus.

21.5.2 FlexCAN2 Addressing and RAM Size

There are 1024 bytes of RAM for a maximum of 64 message buffers. The user can program the maximum number of message buffers (MBs) using the MAXMB field in the CANx_MCR. For this 1024-byte RAM configuration, MAXMB can be any number from 0–63.

21.6 Document Revision History

Table 21-19. Changes Between MPC5565RM Revisions 0.1 and 1

<p>In the Receive Process, Section 21.4.3, “Receive Process,” in the third step, changed “receive active and empty” to EMPTY.</p>
<p>Reworded the first paragraph of Matching Process, Section 21.4.3.1, “Matching Process:”</p> <ul style="list-style-type: none"> From: “After a MB is marked as ‘RX active and empty,’ it will participate in the internal matching process, which takes place every time the receiver receives an error free frame. In this process, all active RX buffers compare their ID value to the newly received one, and if a match occurs, the frame is transferred (move in) to the first (that is, lowest entry) matching MB.” To: “The matching process compares the IDs of all active RX message buffers to newly received frames, so that, if a match occurs, a newly received frame is transferred (moved in) to the first (that is, lowest entry) matching MB. Only MBs marked as EMPTY, FULL, or OVERRUN will participate in the internal matching process at the CRC frame field. The internal matching process takes place every time the receiver receives an error free frame.”
<ul style="list-style-type: none"> In Bus Interface, Section 21.4.8, “Bus Interface,” the following NOTE has been added: “Unused MB space must not be used as general purpose RAM while FlexCAN is transmitting and receiving CAN frames.”
<p>Table 21-4 <i>Message Buffer Field Descriptions</i>: Changed description of the ID field to match register diagram. Changed (28 to 11) to (3 to 13) for the MSB bits and added (14 to 31) for the LSB bits: Standard frame format, only the 11 most significant bits (3 to 13) are used for frame identification in both receive and transmit cases. The 18 least significant bits (14 to 31) are ignored. Extended frame format, all bits are used for frame identification in both receive and transmit cases.</p>
<p>Section 21.3.3.2, “Control Register (CANx_CR): Deleted the following sentence</p> <ul style="list-style-type: none"> Most of the fields in this register should only be changed while the module is disabled or in freeze mode. Table 21-8: CANx_CR Field Descriptions: Deleted from field description for CLK_SRC: To guarantee reliable operation, this bit should only be changed while the module is disabled.

Chapter 22

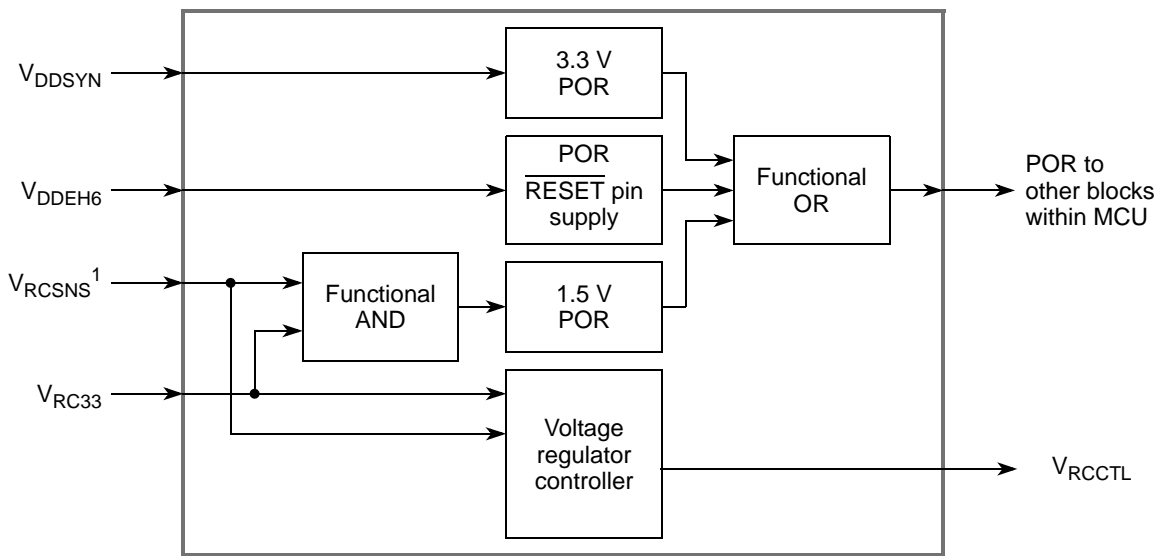

Voltage Regulator Controller (VRC) and POR Module

22.1 Introduction

The voltage regulator controller (VRC) and power-on reset (POR) module contains circuitry to control regulation of the external 1.5 V supply used by the MPC5565. It also contains POR circuits for the 1.5 V supply, V_{DDSYN} and the V_{DDE} supply that powers the $\overline{\text{RESET}}$ pad.

22.1.1 Block Diagram

The block diagram of the VRC and POR module is shown in Figure 22-1. The diagram represents the various submodules as implemented on the device.

¹ This is not a package pin

Figure 22-1. Voltage Regulator Controller and POR Blocks

22.2 External Signal Description

Table 22-1 describes the VRC signals.

Table 22-1. Voltage Regulator Controller and POR Block External Signals

Signal	Type	Signal Level	Description
V_{RC33}	Supply pin	3.3 V	Regulator supply input. 3.3 V VRC supply input.
V_{DDSYN}	Supply pin	3.3 V	FMPLL supply input. This is the 3.3 V supply input for the frequency modulated phase lock loop (FMPLL) module. V_{RCVSS} is connected internally to V_{DDSYN} .
V_{DDEH6}	Supply pin	3.3–5.0 V	\overline{RESET} pin supply input. Power supply input for padding segment that contains the \overline{RESET} pad.
V_{RCSNS}	1.5 V sense	1.5 V	1.5 V sense used by VRC. Pad connected to V_{DD} plane in package—not a package ball. This is the 1.5 V sense from the external 1.5 V supply output of NPN transistor. This input is monitored by the VRC to determine the value for V_{RCCTL} . V_{RCSNS} is a pad on the die that is connected to a V_{DD} plane inside the package. It is not a package ball.
V_{RCCTL}	Current output	—	Regulator control output. The V_{RCCTL} sources base current to the external bypass transistor. The V_{RCCTL} signal is used with internal and external transistors to provide V_{DD} , which is the MCU 1.5 V power supply.
V_{DD}	Supply pin	1.5 V	Internal 1.5 V power supply input.

22.3 Memory Map and Register Definition

The VRC and POR module have no memory-mapped registers.

22.4 Functional Description

The VRC portion of the module contains a voltage regulator controller, and the POR portion contains circuits to monitor the voltage levels of the 1.5 V and V_{DDSYN} power supplies, as well as circuits to monitor the power supply for the \overline{RESET} pad. The PORs indicate whether each supply monitored is above the specified voltage threshold. The PORs ensure that the device is correctly powered up during a power-on reset. POR holds the device in reset when any of the monitored supplies fall below the specified minimum voltage.

22.4.1 Voltage Regulator Controller

The VRC circuit has a control current for use with an external NPN transistor and an external resistor to power the 1.5 V V_{DD} supply. The control current is output on the V_{RCCTL} pin. The voltage regulator controller slowly turns on the pass transistor while the 3.3 V POR is asserted. The pass transistor is completely turned on by the time the 3.3 V POR negates.

The voltage regulator controller keeps the 1.5 V supply in regulation as long as V_{RC33} is in regulation. If more protection is desired, you can also supply an external 1.5 V low voltage reset circuit.

- If the on-chip voltage regulator controller is not used, an external 1.5 V supply is required. To avoid a power sequencing requirement when an external power supply is used, external 3.3 V must power V_{RC33} while the V_{RCCTL} pad is unconnected. In this case, the internal 1.5 V POR remains enabled.
- If V_{RC33} is not powered, the device is subject to the power sequencing requirements for the 1.5 V and 3.3 V, or \overline{RESET} supplies. This ensures that the 1.5 V supply is high enough for internal logic to operate correctly during power-up.

Refer to [Section 22.5.3, “Power Sequencing Requirements”](#) for more information.

22.4.2 POR Circuits

The individual POR circuits asserts whenever the supply being monitored drops below the specified threshold. The entire device is in power-on reset if any of these supplies are below the values specified in the *MPC5565 Microcontroller Data Sheet*.

Power-on reset asserts as soon as possible after the voltage level of the POR supplies begin to rise. Each POR circuit negates before its supply rises to its specified range. Power-on reset remains asserted until all POR supplies rise above the maximum POR threshold. Each POR asserts after its supply drops below its specified range. The behavior for each POR during power sequencing is shown in [Figure 22-2](#).

Before the 3.3 V POR circuit asserts when ramping up, or after it negates when ramping down, the device can exit POR but remain in system reset. In this case, MDO[0] is driving high and no clocks are toggling.

If the 3.3 V POR circuit is asserted, the device behaves as if in POR even if the 1.5 V and \overline{RESET} power POR circuits have not yet asserted when ramping up or have negated when ramping down.

NOTE

The PORs for each supply are not intended to indicate that the voltage has dropped below the specified voltage range. You must monitor the supplies externally and assert \overline{RESET} to achieve precise monitoring.

Figure 22-2. Regions POR is Asserted

22.4.2.1 1.5 V POR Circuit

The 1.5 V POR circuit monitors the voltage on the V_{RCSNS} pad. The 1.5 V POR functions if the V_{RC33} pad is powered. If the user does not power V_{RC33} to the specified voltage, the 1.5 V POR is disabled and the user must follow the specified power sequence.

22.4.2.2 3.3 V POR Circuit

The 3.3 V POR circuit is used to ensure that V_{DDSYN} is high enough that the FMPLL begins to operate correctly.

22.4.2.3 \overline{RESET} Power POR Circuit

The \overline{RESET} power POR circuit monitors the supply that powers the \overline{RESET} pin, and ensures that the voltage supply to the \overline{RESET} pin is high enough to reliably propagate the state of the input. The supply monitored by this POR cannot exceed 5.5 V.

22.5 Initialization and Application Information

22.5.1 Voltage Regulator Example

Figure 22-3 shows how to connect the VRC to the device.

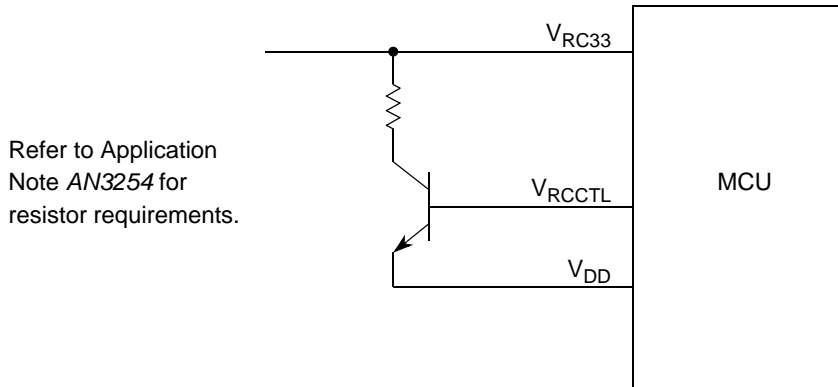

Figure 22-3. Voltage Regulator Controller Hookup

NOTE

Do not use [Figure 22-3](#) as a reference for board design. Refer to *Application Note AN3254* for resistor requirements.

22.5.2 Compatible Power Transistors

The following NPN transistors are compatible with the on-chip VRC:

- ON Semiconductor™ NJD2873
- Phillips Semiconductor™ BCP68

Refer to the *MPC5565 Microcontroller Data Sheet* for information on the operating characteristics.

22.5.3 Power Sequencing Requirements

This section describes the following power sequencing requirements for the device:

- If an external 1.5 V power supply is used and V_{RC33} is tied to ground, power sequencing is required between the 1.5 V power supply, and V_{DDSYN} and the \overline{RESET} power supplies. To avoid this power sequencing requirement, power up V_{RC33} within the specified operating range, even if not using the on-chip voltage regulator controller. Refer to [Section 22.5.3.1, “Power-Up Sequence If \$V_{RC33}\$ Grounded”](#) and [Section 22.5.3.2, “Power-Down Sequence If \$V_{RC33}\$ Grounded.”](#)
- The V_{DD33} voltage must be high enough before POR negates to ensure the values on certain pins are treated as 1s when POR negates. Refer to [Section 22.5.3.3, “Input Value of Pins During POR Dependent on \$V_{DD33}\$.”](#)

- When powering up, power sequencing is not required between V_{RC33} and V_{DDSYN} . However, for the VRC staged turn-on to operate within specification, V_{RC33} must not lead V_{DDSYN} by more than 600 mV, nor lag by more than 100 mV. Higher spikes in the emitter current of the pass transistor occur if V_{RC33} leads or lags V_{DDSYN} by exceeding these tolerances. The value of the current for the higher spikes depends on the board power supply circuitry and the amount of board-level capacitance.
- When powering down, delta tolerances between V_{RC33} and V_{DDSYN} are not required because the bypass capacitors internal and external to the device are already charged.
- When not powering up or down, delta tolerances between V_{RC33} and V_{DDSYN} are not required for the VRC to operate within specification.

22.5.3.1 Power-Up Sequence If V_{RC33} Grounded

The 1.5 V V_{DD} supply must rise to 1.35 V before the 3.3 V V_{DDSYN} and the \overline{RESET} supplies rise above 2.0 V. This ensures that digital logic in the PLL for the 1.5 V supply does not begin to operate below the lower limit of the 1.35 V operation range. Because the internal 1.5 V POR is disabled, the internal 3.3 V POR or the \overline{RESET} power POR must hold the device in reset. Since they can negate as low as 2.0 V, V_{DD} must be within the specification range before the 3.3 V POR and the \overline{RESET} power POR negate.

Figure 22-4. Power-Up Sequence, V_{RC33} Grounded

22.5.3.2 Power-Down Sequence If V_{RC33} Grounded

The only requirement for the power-down sequence when V_{RC33} is grounded is that if V_{DD} decreases to less than its operating range, V_{DDSYN} or the \overline{RESET} power must decrease to less than 2.0 V before the V_{DD} power is allowed to increase to its operating range. This ensures that the digital 1.5 V logic, which is reset by the ORed POR only that can cause the 1.5 V supply to decrease below its specification, is reset correctly.

22.5.3.3 Input Value of Pins During POR Dependent on V_{DD33}

To avoid selecting the bypass clock because PLLCFG[0:1] and $\overline{\text{RSTCFG}}$ were not treated as 1s when POR negates, V_{DD33} must not lag V_{DDSYN} and the $\overline{\text{RESET}}$ pin power when powering the device by more than the VDD33_LAG specification. V_{DD33} can independently lag V_{DDSYN} or $\overline{\text{RESET}}$ by more than the VDD33_LAG specification. The VDD33_LAG specification applies regardless of whether V_{RC33} is powered. The VDD33_LAG specification only applies during power up. V_{DD33} has no lead or lag requirements when powering down.

Refer to the following sections or documents for more information:

[Section 22.5.3.4, “Pin Values after POR Negates”](#)

MPC5565 Microcontroller Data Sheet for the VDD33_LAG specification.

22.5.3.4 Pin Values after POR Negates

Depending on the final PLL mode required, the PLLCFG[0:1] and $\overline{\text{RSTCFG}}$ pins must have the values shown in [Table 22-2](#) after POR negates. Refer to application note *AN2613, “MPC5554 Minimum Board Configuration”* for one example of the external configuration circuit.

Table 22-2. Values after POR Negation

Final PLL Mode	$\overline{\text{RSTCFG}}$	PLLCFG[0]	PLLCFG[1]
Crystal reference. Using $\overline{\text{RSTCFG}}$ to select Crystal Reference as the default.	1	—	—
Crystal reference. Using $\overline{\text{RSTCFG}}$ to <i>not</i> select Crystal Reference as the default.	—	1	—
External reference	0	1	1
Dual-controller	—	1	—

NOTE

After POR negates, $\overline{\text{RSTCFG}}$ and PLLCFG[0:1] can change to their final value, but do not switch through the 0, 0, 0 state on the pins.

Chapter 23

IEEE 1149.1 Test Access Port Controller (JTAGC)

23.1 Introduction

The JTAG port of the device consists of four inputs and one output. These pins include JTAG compliance select (JCOMP), test data input (TDI), test data output (TDO), test mode select (TMS), and test clock input (TCK). TDI, TDO, TMS, and TCK are compliant with the IEEE 1149.1-2001 standard and are shared with the NDI through the test access port (TAP) interface.

23.1.1 Block Diagram

Figure 23-1 is a block diagram of the JTAG Controller (JTAGC).

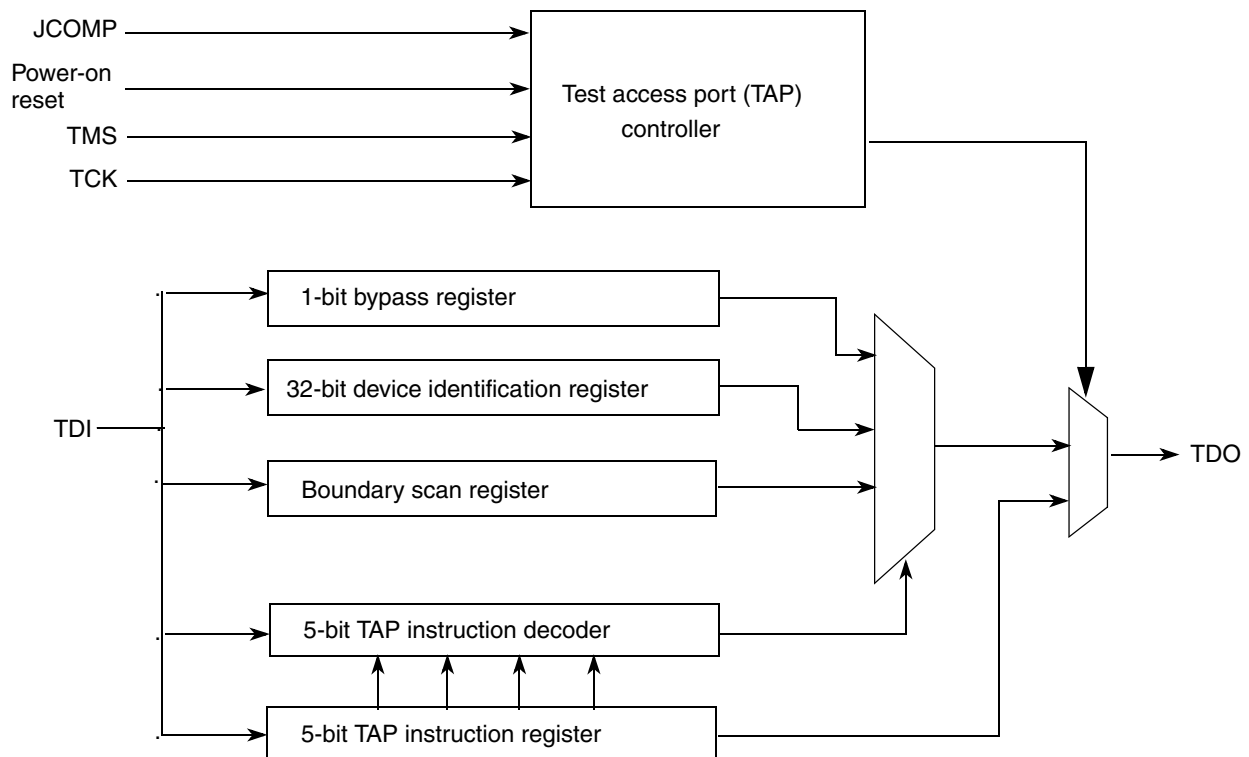

Figure 23-1. JTAG Controller Block Diagram

23.1.2 Overview

The JTAGC provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. In addition, instructions can be executed that allow the Test Access Port (TAP) to be shared with other modules on the MCU. All data input to and output from the JTAGC is communicated in serial format.

23.1.3 Features

The JTAGC is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface.
- 4 pins (TDI, TMS, TCK, and TDO), Refer to [Section 23.2, “External Signal Description.”](#)
- A JCOMP input that provides the ability to share the TAP.
- A 5-bit instruction register that supports several IEEE 1149.1-2001 defined instructions, as well as several public and private MCU specific instructions.
- Four test data registers: a bypass register, a boundary scan register, and a device identification register. The size of the boundary scan register is 464 bits.
- A TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

23.1.4 Modes of Operation

The JTAGC uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

23.1.4.1 Reset

The JTAGC is placed in reset when the TAP controller state machine is in the TEST-LOGIC-RESET state. The TEST-LOGIC-RESET state is entered upon the assertion of the power-on reset signal, negation of JCOMP, or through TAP controller state machine transitions controlled by TMS. Asserting power-on reset or negating JCOMP results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the test-logic-reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered.
- The instruction register is loaded with the IDCODE instruction.

In addition, execution of certain instructions can result in assertion of the internal system reset. These instructions include EXTEST, CLAMP, and HIGHZ.

23.1.4.2 IEEE 1149.1-2001 Defined Test Modes

The JTAGC supports several IEEE 1149.1-2001 defined test modes. The test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data registers that can operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in [Section 23.4.4, “JTAGC Instructions.”](#)

23.1.4.3 Bypass Mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

23.1.4.4 TAP Sharing Mode

There are four selectable auxiliary TAP controllers that share the TAP with the JTAGC. Selectable TAP controllers include the Nexus port controller (NPC), e200 OnCE, eTPU Nexus, and eDMA Nexus. The instructions required to grant ownership of the TAP to the auxiliary TAP controllers are ACCESS_AUX_TAP_NPC, ACCESS_AUX_TAP_ONCE, ACCESS_AUX_TAP_eTPU, ACCESS_AUX_TAP_DMA. Instruction opcodes for each instruction are shown in [Table 23-3](#).

When the access instruction for an auxiliary TAP is loaded, control of the JTAG pins is transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive.

For more information on the TAP controllers refer to [Chapter 24, “Nexus Development Interface.”](#)

23.2 External Signal Description

The JTAGC consists of five signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table:

Table 23-1. JTAG Signal Properties

Name	I/O	Function	Reset State	Pull ¹
TCK	I	Test clock	—	Down
TDI	I	Test data in	—	Up
TDO	O	Test data out	High Z ²	Down ²
TMS	I	Test mode select	—	Up
JCOMP	I	JTAG compliancy	—	Down

¹ The pull is not implemented in this module. Pullup/down devices are implemented in the pads.

² TDO output buffer enable is negated when JTAGC is not in the Shift-IR or Shift-DR states. A weak pulldown can be implemented on TDO.

23.3 Memory Map/Register Definition

This section provides a detailed description of the JTAGC registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

23.3.1 Instruction Register

The JTAGC uses a 5-bit instruction register as shown in [Figure 23-2](#). The instruction register allows instructions to be loaded into the module to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the update-IR and test-logic-reset TAP controller states. Synchronous entry into the test-logic-reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the test-logic-reset state results in asynchronous loading of the IDCODE instruction. During the capture-IR TAP controller state, the instruction shift register is loaded with the value 0b10101, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

Figure 23-2. 5-Bit Instruction Register

23.3.2 Bypass Register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

23.3.3 Device Identification Register

The device identification register, shown in [Figure 23-3](#), allows the part revision number, design center, part identification number, and manufacturer identity code to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the update-DR state.

Figure 23-3. Device Identification Register

Table 23-2. Device Identification Register Field Descriptions

Field	Description
0–3 PRN	Part revision number. Contains the revision number of the device. This field changes with each revision of the device or module.
4–9 DC	Design center. Indicates the Freescale design center. For the MPC5565 this value is 0x20.
10–19 PIN	Part identification number. Contains the part number of the device. For the MPC5565, this value is 0x165.
20–30 MIC	Manufacturer identity code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID for Freescale, 0xE.
31 ID	IDCODE register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

23.3.4 Boundary Scan Register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Section 23.4.5, “Boundary Scan.”](#) The size of the boundary scan register is 464 bits.

23.4 Functional Description

23.4.1 JTAGC Reset Configuration

While in reset, the TAP controller is forced into the test-logic-reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

23.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the JCOMP signal and the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to [Section 23.4.4.2, “ACCESS_AUX_TAP_x Instructions.”](#)

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in [Figure 23-4](#). This applies for the instruction register, test data registers, and the bypass register.

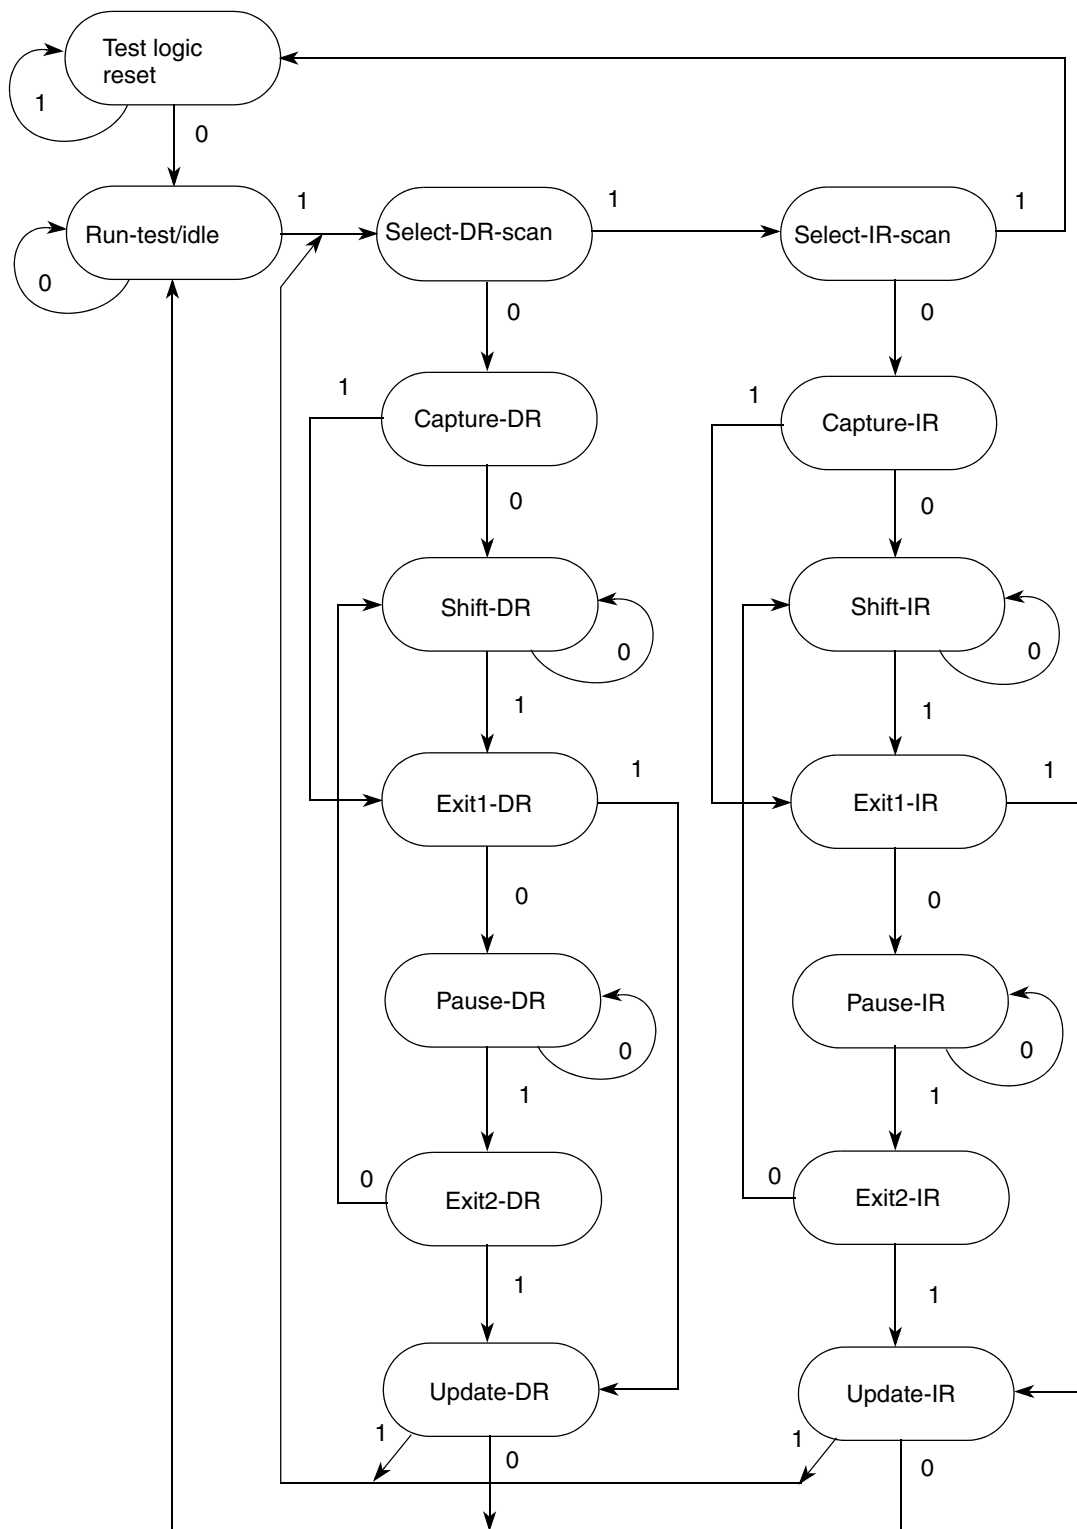

Figure 23-4. Shifting Data Through a Register

23.4.3 TAP Controller State Machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. [Figure 23-5](#) shows the machine’s states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal.

As [Figure 23-5](#) shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the test-logic-reset state.

NOTE: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 23-5. IEEE 1149.1-2001 TAP Controller Finite State Machine

23.4.3.1 Enabling the TAP Controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

23.4.3.2 Selecting an IEEE 1149.1-2001 Register

Access to the JTAGC data registers is done by loading the instruction register with any of the JTAGC instructions while the JTAGC is enabled. Instructions are shifted in via the select-IR-scan path and loaded in the update-IR state. At this point, all data register access is performed via the select-DR-scan path.

The select-DR-scan path is used to read or write the register data by shifting in the data (LSB first) during the shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting can be terminated after fetching the required number of bits.

23.4.4 JTAGC Instructions

This section gives an overview of each instruction, refer to the IEEE 1149.1-2001 standard for more details.

The JTAGC implements the IEEE 1149.1-2001 defined instructions listed in [Table 23-3](#).

Table 23-3. JTAG Instructions

Instruction	Code[4:0]	Instruction Summary
IDCODE	00001	Selects device identification register for shift
SAMPLE/PRELOAD	00010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	00011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	00100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
HIGHZ	01001	Selects bypass register while three-stating all output pins and asserting functional reset
CLAMP	01100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ACCESS_AUX_TAP_NPC	10000	Grants the Nexus port controller (NPC) ownership of the TAP
ACCESS_AUX_TAP_ONCE	10001	Grants the Nexus e200z6 core interface (NZ6C3) ownership of the TAP
ACCESS_AUX_TAP_eTPU	10010	Grants the Nexus dual-eTPU development interface (NDEDI) ownership of the TAP
ACCESS_AUX_TAP_DMA	10011	Grants the Nexus crossbar DMA interface (NXDM) ownership of the TAP
BYPASS	11111	Selects bypass register for data operations

Table 23-3. JTAG Instructions (continued)

Instruction	Code[4:0]	Instruction Summary
Factory Debug Reserved ¹	00101 00110 01010	Intended for factory debug only
Reserved ²	All Other Codes	Decoded to select bypass register

¹ Intended for factory debug, and not customer use

² Freescale reserves the right to change the decoding of reserved instruction codes

23.4.4.1 BYPASS Instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

23.4.4.2 ACCESS_AUX_TAP_x Instructions

The ACCESS_AUX_TAP_x instructions allow the Nexus modules on the MCU to take control of the TAP. When this instruction is loaded, control of the TAP pins is transferred to the selected auxiliary TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive.

23.4.4.3 CLAMP Instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

23.4.4.4 EXTEST — External Test Instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

23.4.4.5 HIGHZ Instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active, all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

23.4.4.6 IDCODE Instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC is reset.

23.4.4.7 SAMPLE Instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the update-DR state. Both the data capture and the shift operation are transparent to system operation.

23.4.4.8 SAMPLE/PRELOAD Instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE part of the instruction samples the system data and control signals on the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising-edge of TCK in the capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD part of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

23.4.5 Boundary Scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

23.5 Initialization/Application Information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC module and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to logic 1, thereby enabling the JTAGC TAP controller.
2. Load the appropriate instruction for the test or action to be performed.

No changes since the last release.

Chapter 24

Nexus Development Interface

24.1 Introduction

The device microcontroller contains multiple Nexus clients that communicate over a single IEEE®-ISTO 5001™-2003 Nexus class 3 combined JTAG IEEE® 1149.1/auxiliary out interface. Combined, all of the Nexus clients are referred to as the Nexus development interface (NDI). Class 3 Nexus allows for program, data, and ownership trace of the microcontroller execution without access to the external data and address buses.

This chapter is organized in the following manner:

- The chapter opens with sections that provide a high level view of the Nexus development interface: [Section 24.1, “Introduction”](#) through [Section 24.8, “NPC Initialization/Application Information.”](#)

The remainder of the chapter contains sections that discuss the remaining the following modules of the Nexus development interface:

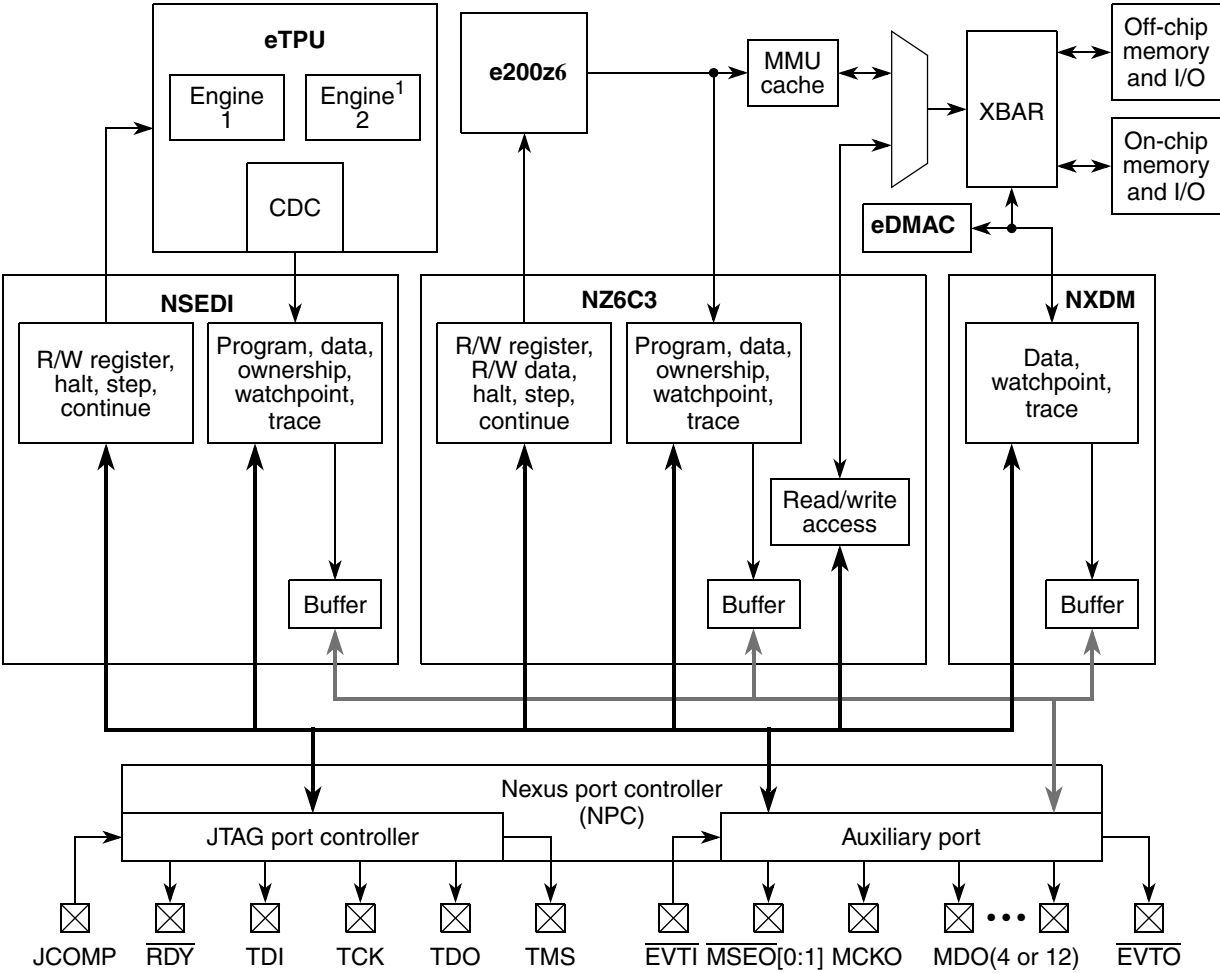

- Nexus single-eTPU development interface (NSEDI). The device has one eTPU engine. Refer to [Section 24.9, “Nexus Single eTPU Development Interface \(NSEDI\)”](#) and the *eTPU Reference Manual* for information about the NSEDI.
- Nexus e200z6 core interface (NZ6C3). In this chapter, the NZ6C3 interface is discussed in [Section 24.10, “e200z6 Class 3 Nexus Module \(NZ6C3\) through Section 24.11, “NZ6C3 Memory Map/Register Definition.”](#)
- Nexus crossbar eDMA interface (NXDM). Refer to [Section 24.12, “Nexus Crossbar eDMA Interface \(NXDM\)”](#)

Communication to the NDI is handled via the auxiliary port and the JTAG port.

- The auxiliary port is comprised of nine or 17 output pins and 1 input pin. The output pins include one message clock out (MCKO) pin, four or 12 message data out (MDO) pins, two message start/end out (MSEO) pins, one ready (RDY) pin, and one event out (EVTO) pin. Event in (EVTI) is the only input pin for the auxiliary port.
- The JTAG port consists of four inputs and one output. These pins include JTAG compliance select (JCOMP), test data input (TDI), test data output (TDO), test mode select (TMS), and test clock input (TCK). TDI, TDO, TMS, and TCK are compliant with the IEEE® 1149.1-2001 standard and are shared with the NDI through the test access port (TAP) interface. JCOMP along with power-on reset and the TAP state machine are used to control reset for the NDI module. Ownership of the TAP is achieved by loading the appropriate enable instruction for the desired Nexus client in the JTAG controller (JTAGC) when JCOMP is asserted. Refer to [Table 24-4](#) for the JTAGC opcodes to access the different Nexus clients.

24.1.1 Block Diagram

Figure 24-1 shows a general block diagram of the NDI components.

¹ Some MPC5500 devices have one eTPU engine, others have two engines.

Figure 24-1. NDI General Block Diagram

24.1.2 Features

The NDI module is compliant with the IEEE-ISTO 5001-2003 standard. The following features are implemented:

- 15- or 23-bit full duplex pin interface for medium and high visibility throughput
 - One of two modes selected by register configuration: full port mode (FPM) and reduced port mode (RPM). FPM comprises 12 MDO pins, and RPM comprises 4 MDO pins.
 - Auxiliary output port
 - One MCKO (message clock out) pin
 - Four or 12 MDO (message data out) pins
 - Two $\overline{\text{MSEO}}$ (message start/end out) pins
 - One $\overline{\text{RDY}}$ (ready) pin
 - One $\overline{\text{EVTO}}$ (event out) pin
 - Auxiliary input port uses one $\overline{\text{EVTI}}$ (event in) pin
 - Five-pin JTAG port (JCOMP, TDI, TDO, TMS, and TCK)
- Host processor (e200z6) development support features (NZ6C3)
 - IEEE-ISTO 5001-2003 standard class 3 compliant.
 - Data trace via data write messaging (DWM) and data read messaging (DRM). This allows the development tool to trace reads and/or writes to selected internal memory resources.
 - Ownership trace via ownership trace messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An ownership trace message is transmitted when a new process/task is activated, allowing development tools to trace ownership flow.
 - Program trace via branch trace messaging (BTM). Branch trace messaging displays program flow discontinuities (direct branches, indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus, static code can be traced.
 - Watchpoint messaging (WPM) via the auxiliary port.
 - Watchpoint trigger enable of program and/or data trace messaging.
 - Data tracing of instruction fetches via private opcodes.
 - Subset of Power Architecture Book E software debug facilities with OnCE block (Nexus class 1 features).
- eDMA development support features (NXDM)
 - Data trace via data write messaging (DWM) and data read messaging (DRM). This allows the development tool to trace DMA generated reads and/or writes to selected address ranges in the device's memory map.
 - Watchpoint messaging (WPM) via the auxiliary port.
 - Watchpoint trigger enable/disable of data trace messaging.

- eTPU development support features (NSEDI)
 - IEEE-ISTO 5001-2002 standard Class 3 compliant for the eTPU engine.
 - Data trace via data write messaging and data read messaging. This allows the development tool to trace reads and writes to selected shared parameter RAM (SPRAM) address ranges. Four data trace windows are shared by the two eTPU engines.
 - Ownership trace via ownership trace messaging (OTM). OTM facilitates ownership trace by providing visibility of which channel is being serviced. An ownership trace message is transmitted to indicate when a new channel service request is scheduled, allowing the development tools to trace task flow. A special OTM is sent when the engine enters in idle state, meaning that all requests were serviced and no new requests are yet scheduled.
 - Program trace via branch trace messaging. BTM displays program flow discontinuities (start, jumps, return, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code can be traced. The branch trace messaging method uses the branch/predicate method to reduce the number of generated messages.
 - Watchpoint messaging via the auxiliary port. WPM provides visibility of the occurrence of the eTPU's watchpoints and breakpoints.
 - Nexus based breakpoint/watchpoint configuration and single step support.
- Run-time access to the on-chip memory map via the Nexus read/write access protocol. This feature supports accesses for run-time internal visibility, calibration variable acquisition, calibration constant tuning, and external rapid prototyping for powertrain automotive development systems.
- All features are independently configurable and controllable via the IEEE® 1149.1 I/O port.
- The NDI block reset is controlled with JCOMP, power-on reset, and the TAP state machine. These sources are independent of system reset.
- System clock locked status indication via MDO0 following power-on reset.

24.1.3 Modes of Operation

The NDI block is in reset when the TAP controller state machine is in the TEST-LOGIC-RESET state. The TEST-LOGIC-RESET state is entered on the assertion of the power-on reset signal, negation of JCOMP, or through state machine transitions controlled by TMS. Assertion of JCOMP allows the NDI to move out of the reset state, and is a prerequisite to grant Nexus clients control of the TAP. Ownership of the TAP is achieved by loading the appropriate enable instruction for the desired Nexus client in the JTAGC controller (JTAGC) block when JCOMP is asserted.

Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. In PLL bypass mode, the NDI can transition out of the reset state immediately following negation of power-on reset. Refer to [Section 24.4.5, “System Clock Locked Indication”](#) for more details.

24.1.3.1 Nexus Reset Mode

In Nexus reset mode, the following actions occur:

- Register values default back to their reset values.
- The message queues are marked as empty.
- The auxiliary output port pins are negated if the NDI controls the pads.
- The TDO output buffer is disabled if the NDI has control of the TAP.
- The TDI, TMS, and TCK inputs are ignored.
- The NDI block indicates to the MCU that it is not using the auxiliary output port. This indication can be used to three-state the output pins or use them for another function.

24.1.3.2 Full-Port Mode

In full-port mode, all the available MDO pins are used to transmit messages. All trace features are enabled or can be enabled by writing the configuration registers via the JTAG port. The number of MDO pins available is 12.

24.1.3.3 Reduced-Port Mode

In reduced-port mode, a subset of the available MDO pins are used to transmit messages. All trace features are enabled or can be enabled by writing the configuration registers via the JTAG port. The number of MDO pins available is 4. Unused MDO (MDO[11:4]) pins can be used as GPIO. Details on GPIO functionality configuration can be found in [Chapter 6, “System Integration Unit \(SIU\).”](#)

24.1.3.4 Disabled-Port Mode

In disabled-port mode, message transmission is disabled. Any debug feature that generates messages can not be used. The primary features available are class 1 features and read/write access.

24.1.3.5 Censored Mode

When the device is in censored mode, reading the contents of internal flash externally is not allowed. To prevent Nexus modules from violating censorship, the NPC is held in reset when in censored mode, asynchronously holding all other Nexus modules in reset as well. This prevents Nexus read/write to memory mapped resources and the transmission of Nexus trace messages. Refer to [Table 13-16](#) for information on Nexus port enabling and disabling regarding censorship.

24.2 External Signal Description

The auxiliary and JTAG pin interfaces provide for the transmission of messages from Nexus modules to the external development tools and for access to Nexus client registers. The auxiliary/JTAG pin definitions are outlined in [Table 24-1](#).

Table 24-1. Signal Properties

Signal Name	Port	Function	Reset State
$\overline{\text{EVTO}}$	Auxiliary	Event out pin	Negated
$\overline{\text{EVTI}}$	Auxiliary	Event in pin	Pullup
MCKO	Auxiliary	Message clock out pin (from NPC)	Enabled
MDO[3:0] or MDO[11:0]	Auxiliary	Message data out pins	Driven Low ¹
$\overline{\text{MSEO}}[1:0]$	Auxiliary	Message start/end out pins	Negated
$\overline{\text{RDY}}$	Auxiliary	Ready out pin	Negated
JCOMP	JTAG	JTAG compliancy and TAP sharing control	Pulldown
TCK	JTAG	Test clock input	Pulldown
TDI	JTAG	Test data input	Pullup
TDO	JTAG	Test data output	Pullup
TMS	JTAG	Test mode select input	Pullup

¹ Following a power-on reset, MDO[0] remains asserted until power-on reset is exited and the system clock achieves lock.

24.2.1 Detailed Signal Descriptions

This section describes each of the signals listed in [Table 24-1](#) in more detail.

24.2.1.1 Event Out ($\overline{\text{EVTO}}$)

$\overline{\text{EVTO}}$ is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication or to signify that an event has occurred. The $\overline{\text{EVTO}}$ output of the NPC is generated based on the values of the individual $\overline{\text{EVTO}}$ signals from all Nexus modules that implement the signal.

24.2.1.2 Event In ($\overline{\text{EVTI}}$)

$\overline{\text{EVTI}}$ is used to initiate program and data trace synchronization messages or to generate a breakpoint. $\overline{\text{EVTI}}$ is edge-sensitive for synchronization and breakpoint generation.

24.2.1.3 Message Data Out (MDO[3:0] or [11:0])

Message data out (MDO) are output pins used for uploading OTM, BTM, DTM, and other messages to the development tool. The development tool should sample MDO on the rising edge of MCKO. The width of the MDO bus used is determined by the Nexus PCR[FPM] configuration.

Following a power-on reset, MDO0 remains asserted until power-on reset is exited and the system clock achieves lock.

24.2.1.4 Message Start/End Out ($\overline{\text{MSEO}}[1:0]$)

$\overline{\text{MSEO}}[1:0]$ are output pins that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool should sample the $\overline{\text{MSEO}}$ pins on the rising edge of MCKO.

24.2.1.5 Ready ($\overline{\text{RDY}}$)

$\overline{\text{RDY}}$ is an output pin that indicates when a device is ready for the next access.

24.2.1.6 JTAG Compliancy (JCOMP)

The JCOMP signal enables or disables the TAP controller. The TAP controller is enabled when JCOMP asserted, otherwise the TAP controller remains in reset.

24.2.1.7 Test Data Output (TDO)

The TDO pin transmits serial output for instructions and data. TDO is tri-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

24.2.1.8 Test Clock Input (TCK)

The TCK pin is used to synchronize the test logic and control register access through the JTAG port.

24.2.1.9 Test Data Input (TDI)

The TDI pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

24.2.1.10 Test Mode Select (TMS)

The TMS pin is used to sequence the IEEE® 1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

24.3 Memory Map

The NDI block contains no memory mapped registers. Nexus registers are accessed by the development tool via the JTAG port using a register index and a client select value. The client select is controlled by loading the correct access instruction into the JTAG controller; refer to [Table 24-4](#). OnCE registers are accessed by loading the appropriate value in the RS[0:6] field of the OnCE command register (OCMD) via the JTAG port.

[Table 24-2](#) shows the NDI registers by Client Source ID and Index values.

Table 24-2. NDI Registers

Client Source ID	Index	Register

011 0001	Debug Control Register 0 (DBCR0)
011 0010	Debug control register 1 (DBCR1)
011 0011	Debug control register 2 (DBCR2)
011 0100	Debug control register 3 (DBCR3)
011 0101–101 1111	Reserved (do not access)
111 0000–111 1011	General purpose register selects [0:11]
111 1100	Nexus3-access
111 1101	LSRL select
111 1110	Enable_OnCE (and bypass)
111 1111	Bypass

24.4 NDI Functional Description

24.4.1 Enabling Nexus Clients for TAP Access

After the NDI is out of the reset state, the loading of a specific instruction in the JTAG controller (JTAGC) block is required to grant the NDI ownership of the TAP. Each Nexus client has its own JTAGC instruction opcode for ownership of the TAP, granting that client the means to read/write its registers. The JTAGC instruction opcode for each Nexus client is shown in [Table 24-4](#). After the JTAGC opcode for a client has been loaded, the client is enabled by loading its NEXUS-ENABLE instruction. The NEXUS-ENABLE instruction opcode for each Nexus client is listed in [Table 24-5](#). Opcodes for all other instructions supported by Nexus clients can be found in the relevant sections of this chapter.

Table 24-4. JTAG Client Select Instructions

JTAGC Instruction	Opcode	Description
ACCESS_AUX_TAP_NPC	10000	Enables access to the NPC TAP controller
ACCESS_AUX_TAP_ONCE	10001	Enables access to the e200z6 OnCE TAP controller
ACCESS_AUX_TAP_DMA	10011	Enables access to the eDMA Nexus TAP controller

Table 24-5. Nexus Client JTAG Instructions

Instruction	Description	Opcode
NPC JTAG Instruction Opcodes		
NEXUS_ENABLE	Opcode for NPC Nexus Enable instruction (4-bits)	0x0
BYPASS	Opcode for the NPC BYPASS instruction (4-bits)	0xF
e200z6 OnCE JTAG Instruction Opcodes ¹		
NEXUS3_ACCESS	Opcode for e200z6 OnCE Nexus Enable instruction (10-bits)	0x7C
BYPASS	Opcode for the e200z6 OnCE BYPASS instruction (10-bits)	0x7F
eDMA Nexus JTAG Instruction Opcodes		
NEXUS_ACCESS	Opcode for eDMA Nexus Enable instruction (4-bits)	0x0
BYPASS	Opcode for the eDMA Nexus BYPASS instruction (4-bits)	0xF

¹ Refer to the e200z6 Reference Manual for a complete list of available OnCE instructions.

24.4.2 Configuring the NDI for Nexus Messaging

The NDI is placed in disabled mode upon exit of power-on reset. If message transmission via the auxiliary port is desired, a write to the port configuration register (PCR) located in the NPC is then required to enable the NDI and select the mode of operation. Asserting MCKO_EN in the PCR places the NDI in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field.

Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively. When writing to the PCR, the PCR lsb (least significant bit) must be written to a logic 0. Setting the lsb of the PCR enables factory debug mode and prevents the transmission of Nexus messages.

Table 24-6 describes the NDI configuration options.

Table 24-6. NDI Configuration Options

JCOMP Asserted	MCKO_EN bit of the Port Configuration Register	FPM bit of the Port Configuration Register	Configuration
No	X	X	Reset
Yes	0	X	Disabled
Yes	1	1	Full-Port Mode
Yes	1	0	Reduced-Port Mode

24.4.3 Programmable MCKO Frequency

MCKO is an output clock to the development tools used for the timing of $\overline{\text{MSEO}}$ and MDO pin functions. MCKO is derived from the system clock, and its frequency is determined by the value of the MCKO_DIV field in the port configuration register (PCR) located in the NPC. Possible operating frequencies include one-half, one-quarter, and one-eighth system clock speed.

Table 24-7 shows the MCKO_DIV encodings. In this table, SYS_CLK represents the system clock frequency. The default value selected if a reserved encoding is programmed is SYS_CLK/2.

Table 24-7. MCKO_DIV Values

MCKO_DIV[2:0]	MCKO Frequency
0b000	SYS_CLK
0b001	SYS_CLK/2
0b010	Reserved
0b011	SYS_CLK/4
0b100	Reserved
0b101	Reserved
0b110	Reserved
0b111	SYS_CLK/8

24.4.4 Nexus Messaging

Most of the messages transmitted by the NDI include a SRC field. This field is used to identify which source generated the message. Table 24-8 shows the values used for the SRC field by the different clients on the device. These 4-bit values are specific to the device. The same values are used for the client select values written to the client select control register.

Table 24-8. SRC Packet Encodings

SRC[3:0]	Client
0b0000	e200z6
0b0001	eDMA
0b0101-0b1111	Reserved

24.4.5 System Clock Locked Indication

Following a power-on reset, the lsb of the auxiliary output port pins (MDO0) can be monitored to provide the lock status of the system clock. MDO0 is driven to a logic 1 until the system clock achieves lock after exiting power-on reset. After the system clock is locked, MDO0 is negated and tools may begin Nexus configuration. Loss of lock conditions that occur subsequent to the exit of power-on reset and the initial lock of the system clock do not cause a Nexus reset, and therefore do not result in MDO0 driven high.

24.5 Nexus Port Controller (NPC)

The Nexus port controller (NPC) is that part of the NDI that controls access and arbitration of the device’s internal Nexus modules. The NPC contains the port configuration register (PCR) and the device identification register (DID). The contents of the NPC DID are the same as the JTAGC device identification register.

24.5.1 Overview

The device incorporates multiple modules that require development support. Each of these modules implements a development interface based on the IEEE-ISTO 5001-2001 standard and must share the input and output ports that interface with the development tool. The NPC controls the usage of these ports in a manner that allows the individual modules to share the ports, while appearing to the development tool as a single module.

24.5.2 Features

The NPC performs the following functions:

- Controls arbitration for ownership of the Nexus auxiliary output port
- Nexus device identification register and messaging
- Generates MCKO enable and frequency division control signals
- Controls sharing of $\overline{\text{EVTO}}$
- Control of the device-wide debug mode
- Generates asynchronous reset signal for Nexus modules based on JCOMP input, censorship status, and power-on reset status
- System clock locked status indication via MDO[0] during Nexus reset
- Provides Nexus support for censorship mode

24.6 Memory Map/Register Definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

24.6.1 Memory Map

Table 24-9 shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC does not implement the client select control register because the value does not matter when accessing the registers. Note that the bypass register (refer to Section 24.6.2.1, “Bypass Register”) and instruction register (refer to Section 24.6.2.2, “Instruction Register”) have no index values. These registers are not accessed in the same manner as Nexus client registers.

Table 24-9. NPC Memory Map

Index	Register Name	Register Description	Size (bits)
0	DID	Device ID register	32
127	PCR	Port configuration register	32

24.6.2 Register Descriptions

This section consists of NPC register descriptions. Additional information regarding references to the TAP controller state may be found in Section 23.4.3, “TAP Controller State Machine.”

24.6.2.1 Bypass Register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

24.6.2.2 Instruction Register

The NPC uses a 4-bit instruction register as shown in Figure 24-2. The instruction register is accessed via the SELECT_IR_SCAN path of the tap controller state machine, and allows instructions to be loaded into the module to enable the NPC for register access (NEXUS_ENABLE) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and test-logic-reset TAP controller states. Synchronous entry into the test-logic-reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the test-logic-reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register’s read value when the TAP controller is sequenced into the Shift-IR state.

Figure 24-2. 4-Bit Instruction Register

24.6.2.3 Nexus Device ID Register (DID)

The NPC device identification register, shown in [Figure 24-3](#), allows the part revision number, design center, part identification number, and manufacturer identity code of the part to be determined through the auxiliary output port.

Figure 24-3. Nexus Device ID Register (DID)

Table 24-10. DID Register Field Descriptions

Field	Description
31–28 PRN	Part revision number. Contains the revision number of the part. This field changes with each revision of the device or module.
27–22 DC	Design center. Indicates the Freescale design center. This value is 0x20.
21–12 PIN	Part identification number. Contains the part number of the device. The PIN for the MPC5565 is 0x165.
11–1 MIC	Manufacturer identity code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID for Freescale, 0xE.
0	Fixed per JTAG 1149.1 Always set to 1.

24.6.2.4 Port Configuration Register (PCR)

The PCR, shown in [Figure 24-4](#), is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register must be configured as soon as the NPC is enabled.

NOTE

The mode (MCKO_GT) or clock division (MCKO_DIV) bits must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

Figure 24-4. Port Configuration Register (PCR)

Table 24-11. PCR Field Descriptions

Field	Description
31 FPM	Full port mode. Determines if the auxiliary output port uses the full MDO port or a reduced MDO port to transmit messages. 0 The subset of MDO[3:0] pins are used to transmit messages. 1 All MDO[11:0] pins are used to transmit messages. Section 6.3.1.44, “Pad Configuration Register 82–75 (SIU_PCR82–SIU_PCR75)” shows how GPIO is enabled or disabled by the FPM setting.
30 MCKO_GT	MCKO clock gating control. Enables or disables MCKO clock gating. If clock gating is enabled, the MCKO clock is gated when the NPC is in enabled mode but not actively transmitting messages on the auxiliary output port. When clock gating is disabled, MCKO is allowed to run even if no auxiliary output port messages are being transmitted. 0 MCKO gating is disabled. 1 MCKO gating is enabled.
29 MCKO_EN	MCKO enable. Enables the MCKO clock. When enabled, the frequency of MCKO is determined by the MCKO_DIV field. 0 MCKO clock is driven to zero. 1 MCKO clock is enabled.

Table 24-11. PCR Field Descriptions (continued)

Field	Description																		
28–26 MCKO_DIV [2:0]	<p>MCKO division factor. Determines the frequency of MCKO relative to the system clock frequency when MCKO_EN is asserted. The table below shows the meaning of MCKO_DIV values. 0 PSTAT_EN	<p>Processor status mode enable. Enables processor status (PSTAT) mode. In PSTAT mode, all auxiliary output port MDO pins are used to transmit processor status information, and Nexus messaging is unavailable.</p> <p>0 PSTAT mode disabled 1 PSTAT mode enabled</p> <p>Note: PSTAT mode is intended for factory processor debug only. The PSTAT_EN bit should be written to disable PSTAT mode by the customer. No Nexus messages are transmitted under any circumstances when PSTAT mode is enabled</p>																		

24.7 NPC Functional Description

24.7.1 NPC Reset Configuration

The NPC is placed in disabled mode upon exit of reset. If message transmission via the auxiliary port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

Table 24-12 describes the NPC reset configuration options.

Table 24-12. NPC Reset Configuration Options

JCOMP Asserted?	PCR[MCKO_EN]	PCR[FPM]	Configuration
No	X	X	Reset
Yes	0	X	Disabled
Yes	1	1	Full-Port Mode
Yes	1	0	Reduced-Port Mode

24.7.2 Auxiliary Output Port

The auxiliary output port is shared by each of the Nexus modules on the device. The NPC communicates with each of the individual modules and arbitrates for access to the port. Additional information about the auxiliary port is found in [Section 24.2, “External Signal Description.”](#)

24.7.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the $\overline{\text{MSEO}}$ functions. The $\overline{\text{MSEO}}$ pins are used to signal the end of variable-length packets and the end of messages. They are not required to indicate the end of fixed-length packets. MDO and $\overline{\text{MSEO}}$ are sampled on the rising edge of MCKO.

Figure 24-5 illustrates the state diagram for $\overline{\text{MSEO}}$ transfers. All transitions not included in the figure are reserved, and must not be used.

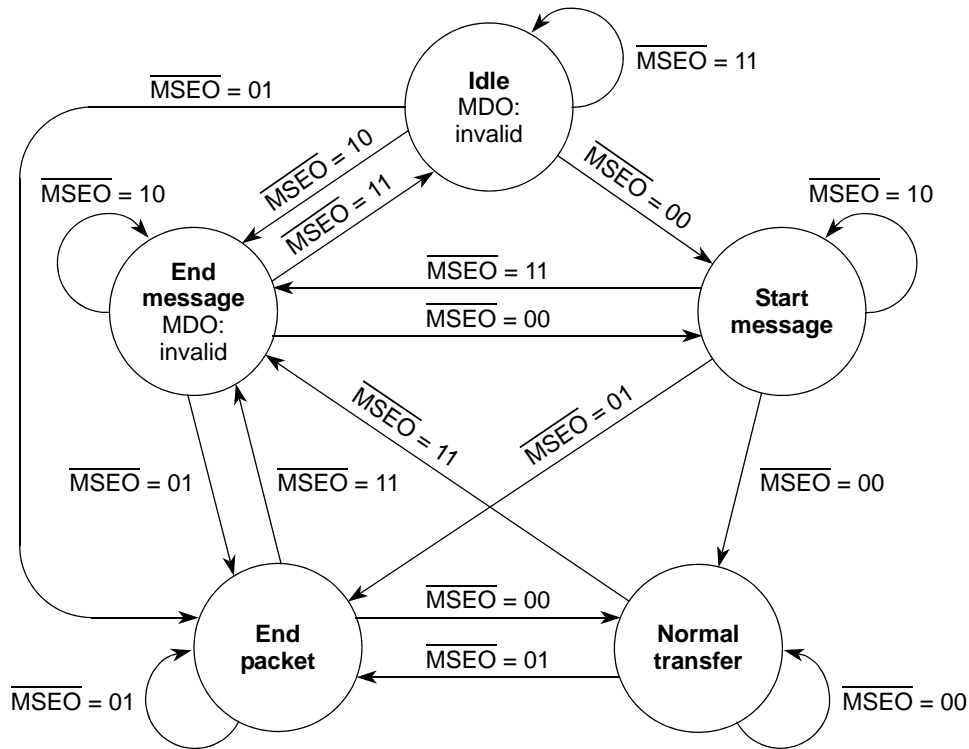

Figure 24-5. $\overline{\text{MSEO}}$ Transfers

24.7.2.2 Output Messages

In addition to sending out messages generated in other Nexus modules, the NPC can also output the device ID message contained in the device ID register on the MDO pins. The device ID message can also be sent out serially through TDO.

Table 24-13 describes the device ID message that the NPC can transmit on the auxiliary port. The TCODE is the first packet transmitted.

Table 24-13. NPC Output Messages

Message Name	Min. Packet Bits	Max Packet Bits	Packet Type	Packet Name	Packet Description
Device ID Message	6	6	Fixed	TCODE	Value = 1
	32	32	Fixed	ID	DID register contents

Figure 24-6 shows the various message formats that the pin interface formatter has to encounter.

Figure 24-6. Message Field Sizes

Message	TCODE	Field #1	Field #2	Field #3	Field #4	Field #5	Min. Size ¹ Bits	Max. Size ² Bits
Device ID Message	1	Fixed = 32	N/A	N/A	N/A	N/A	38	38

¹ Minimum information size. The actual number of bits transmitted depends on the number of MDO pins

² Maximum information size. The actual number of bits transmitted depends on the number of MDO pins

The double edges in Figure 24-6 indicate the starts and ends of messages. Fields without shaded areas between them are grouped into super-fields and can be transmitted together without end-of-packet indications between them.

24.7.2.2.1 Rules of Messages

The rules of messages include the following:

- A variable-sized field within a message must end on a port boundary. (Port boundaries depend on the number of MDO pins active with the current reset configuration.)
- A variable-sized field may start within a port boundary only when following a fixed-length field.
- Super-fields must end on a port boundary.
- When a variable-length field is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary.
- Multiple fixed-length packets may start and/or end on a single clock.
- When any packet follows a variable-length packet, it must start on a port boundary.
- The field containing the TCODE number is always transferred out first, followed by subsequent fields of information.
- Within a field, the lowest significant bits are shifted out first. Figure 24-7 shows the transmission sequence of a message that is made up of a TCODE followed by three fields.

Figure 24-7. Transmission Sequence of Messages

24.7.2.3 IEEE® 1149.1-2001 (JTAG) TAP

The NPC uses the IEEE® 1149.1-2001 TAP for accessing registers. Each of the individual Nexus modules on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. Detailed information about the TAP controller state machine may be found in [Section 23.4.3, “TAP Controller State Machine.”](#)

The IEEE® 1149.1-2001 specification may be ordered for further detail on electrical and pin protocol compliance requirements.

The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE® 1149.1-2001 state machine shown in [Figure 24-5](#). The Nexus controller state machine is defined by the IEEE-ISTO 5001-2003 standard. It is shown in [Figure 24-10](#).

The instructions implemented by the NPC TAP controller are listed in [Table 24-14](#). The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4-bits.

Table 24-14. Implemented Instructions

Instruction Name	Private/Public	Opcode	Description
NEXUS-ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NPC registers.
BYPASS	Private	0xF	NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in [Figure 24-8](#). This applies for the instruction register and all Nexus tool-mapped registers.

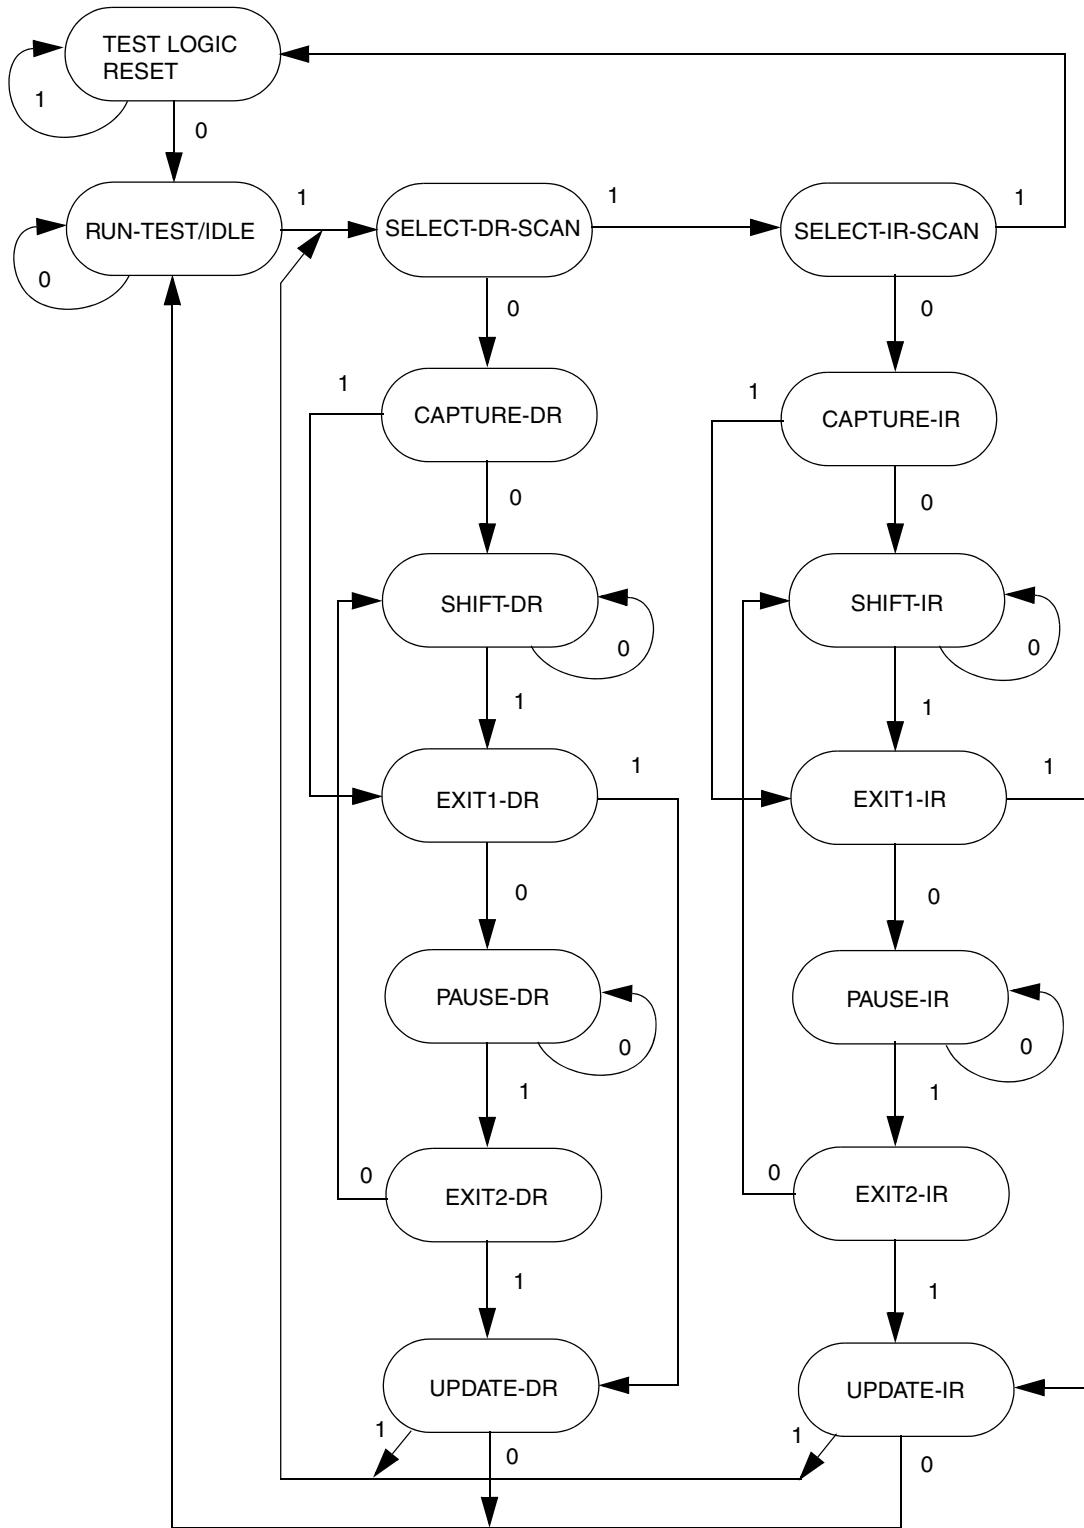

Figure 24-8. Shifting Data Into a Register

24.7.2.3.1 Enabling the NPC TAP Controller

Assertion of the power-on reset signal, entry into censored mode, or negating JCOMP resets the NPC TAP controller. When not in power-on reset or censored mode, the NPC TAP controller is enabled by asserting JCOMP and loading the ACCESS_AUX_TAP_NPC instruction in the JTAGC. Loading the NEXUS-ENABLE instruction then grants access to NPC registers.

NOTE: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 24-9. IEEE 1149.1-2001 TAP Controller State Machine

24.7.2.3.2 Retrieving Device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the auxiliary output port or shifted out serially by accessing the NPC device ID register through the TAP. If the NPC is enabled, transmission of the device identification message on the auxiliary output port MDO pins occurs immediately after a write to the PCR. Transmission of the device identification message serially through TDO is achieved by performing a read of the register contents as described in [Section 24.7.2.3.4, “Selecting a Nexus Client Register.”](#)

24.7.2.3.3 Loading NEXUS-ENABLE Instruction

Access to the NPC registers is enabled by loading the NPC NEXUS-ENABLE instruction when NPC has ownership of the TAP. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in [Figure 24-10](#), transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. [Table 24-15](#) illustrates the IEEE® 1149.1 sequence to load the NEXUS-ENABLE instruction.

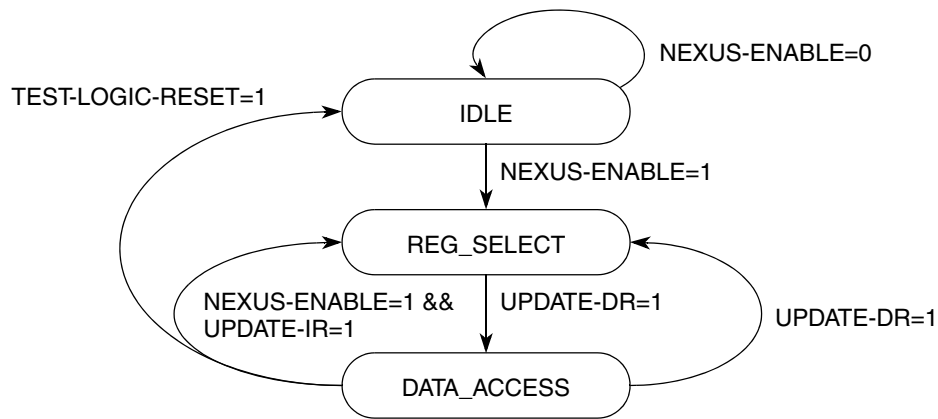

Figure 24-10. NEXUS Controller State Machine

Table 24-15. Loading NEXUS-ENABLE Instruction

Clock	TDI	TMS	IEEE® 1149.1 State	Nexus State	Description
0	—	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	—	1	SELECT-DR-SCAN	IDLE	Transitional state
2	—	1	SELECT-IR-SCAN	IDLE	Transitional state
3	—	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	—	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE® 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction.
5-7	0	0	3 TCKS in SHIFT-IR	IDLE	
8	0	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
9	—	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
10	—	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

24.7.2.3.4 Selecting a Nexus Client Register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path of the IEEE® 1149.1–2001 TAP controller state machine. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the lsb followed by a 7-bit register address index, as illustrated in Figure 24-11. The read/write control bit is set to 1 for writes and 0 for reads.

Figure 24-11. IEEE® 1149.1 Controller Command Input

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (lsb first) during the SHIFT-DR state. When reading a register, the register value is loaded into the IEEE® 1149.1-2001 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE® 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

Table 24-16 illustrates a sequence that writes a 32-bit value to a register.

Table 24-16. Write to a 32-Bit Nexus Client Register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.

Table 24-16. Write to a 32-Bit Nexus Client Register (continued)

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

24.7.2.4 Nexus Auxiliary Port Sharing

Each of the Nexus modules on the MCU implements a request/grant scheme to arbitrate for control of the Nexus auxiliary port when Nexus data is ready to be transmitted.

All modules arbitrating for the port are given fixed priority levels relative to each other. If multiple modules have the same request level, this priority level is used as a tie-breaker. To avoid monopolization of the port, the module given the highest priority level alternates following each grant. Immediately out of reset the order of priority, from highest to lowest, is: NPC, NZ6C3, NSEDI, NXDM. This arbitration mechanism is controlled internally and is not programmable by tools or the user.

24.7.2.5 Nexus JTAG Port Sharing

Each of the individual Nexus modules on the device implements a TAP controller for accessing its registers. When JCOMP is asserted, only the module whose ACCESS_AUX_TAP instruction is loaded has control of the TAP (Refer to [Section 23.4.4, “JTAGC Instructions”](#)). This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. After a Nexus module has ownership of the TAP, that module acts like a single-bit shift register, or bypass register, if no register is selected as the shift path.

24.7.2.6 MCKO

MCKO is an output clock to the development tools used for the timing of $\overline{\text{MSE0}}$ and MDO pin functions. MCKO is derived from the system clock and its frequency is determined by the value of the MCKO_DIV[2:0] field in the PCR. Possible operating frequencies include one-half, one-quarter, and one-eighth system clock speed. MCKO is enabled by setting the MCKO_EN bit in the PCR.

The NPC also controls dynamic MCKO clock gating when in full- or reduced-port modes. The setting of the MCKO_GT bit inside the PCR determines whether or not MCKO gating control is enabled. The MCKO_GT bit resets to a logic 0. In this state gating of MCKO is disabled. To enable gating of MCKO, the MCKO_GT bit in the PCR is written to a logic 1. When MCKO gating is enabled, MCKO is driven to a logic 0 if the auxiliary port is enabled but not transmitting messages and there are no pending messages from Nexus clients.

24.7.2.7 $\overline{\text{EVTO}}$ Sharing

The NPC controls sharing of the $\overline{\text{EVTO}}$ output between all Nexus clients that produce an $\overline{\text{EVTO}}$ signal. $\overline{\text{EVTO}}$ is driven for one MCKO period whenever any module drives its $\overline{\text{EVTO}}$. When there is no active MCKO, such as in disabled mode, the NPC assumes an MCKO frequency of one-half system clock speed when driving $\overline{\text{EVTO}}$. $\overline{\text{EVTO}}$ sharing is active as long as the NPC is not in reset.

24.7.2.8 Nexus Reset Control

The JCOMP input that is used as the primary reset signal for the NPC is also used by the NPC to generate a single-bit reset signal for other Nexus modules. If JCOMP is negated, an internal reset signal is asserted, indicating that all Nexus modules should be held in reset. This internal reset signal is also asserted during a power-on reset, or if nex_disable is asserted (SIU_CCR[DISNEX]), indicating the device is in censored mode. This single bit reset signal functions much like the IEEE® 1149.1-2001 defined TRST signal and allows JCOMP reset information to be provided to the Nexus modules without each module having to sense the JCOMP signal directly or monitor the status of censored mode.

24.8 NPC Initialization/Application Information

24.8.1 Accessing NPC Tool-Mapped Registers

To initialize the TAP for NPC register accesses, the following sequence is required:

1. Enable the NPC TAP controller. This is achieved by asserting JCOMP and loading the ACCESS_AUX_TAP_NPC instruction in the JTAGC.
2. Load the TAP controller with the NEXUS-ENABLE instruction.

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.
2. Read the register value with a second pass through the SELECT-DR-SCAN path. Data shifted in is ignored.

Refer to the IEEE®-ISTO 5001-2003 standard for more detail.

24.9 Nexus Single eTPU Development Interface (NSEDI)

The enhanced timing processor unit (eTPU) has its own Nexus class 3 interface, the Nexus single eTPU development interface (NSEDI). The single eTPU engine and a coherent dual parameter controller (CDC) appear as two separate Nexus clients. Refer to the *Enhanced Time Processor Unit Reference Manual* for more information about the NSEDI module.

Figure 24-12. NSEDI Device ID Register (DID)

Table 24-17. NSEDI DID Register Field Descriptions

Field	Description
31–28 PRN	Part revision number. Contains the revision number of the part. This field changes with each revision of the device or module.
27–22 DC	Design center. Indicates the Freescale design center. This value is 0x20.
21–12 PIN	Part identification number. Contains the part number of the device. The PIN for the MPC5565 is 0x124.
11–1 MIC	Manufacturer identity code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID for Freescale, 0xE.
0	Fixed per JTAG 1149.1 1 Always set

24.10 e200z6 Class 3 Nexus Module (NZ6C3)

The NZ6C3 module provides real-time development capabilities for the device core in compliance with the IEEE®-ISTO Nexus 5001-2003 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

24.10.1 Introduction

This section defines the auxiliary pin functions, transfer protocols and standard development features of the NZ6C3 module. The development features supported are Program trace, data trace, watchpoint messaging, ownership trace, and read/write access via the JTAG interface.

NOTE

Throughout this section references are made to the auxiliary port and its specific signals, such as MCKO, MSEO[0:1], MDO[11:0] and others. In actual use, the device NPC module arbitrates the access of the single auxiliary port. To simplify the description of the function of the NZ6C3 module, the interaction of the NPC is omitted and the behavior described as if the module has its own dedicated auxiliary port. The auxiliary port is fully described in [Section 24.2, “External Signal Description.”](#)

24.10.2 Block Diagram

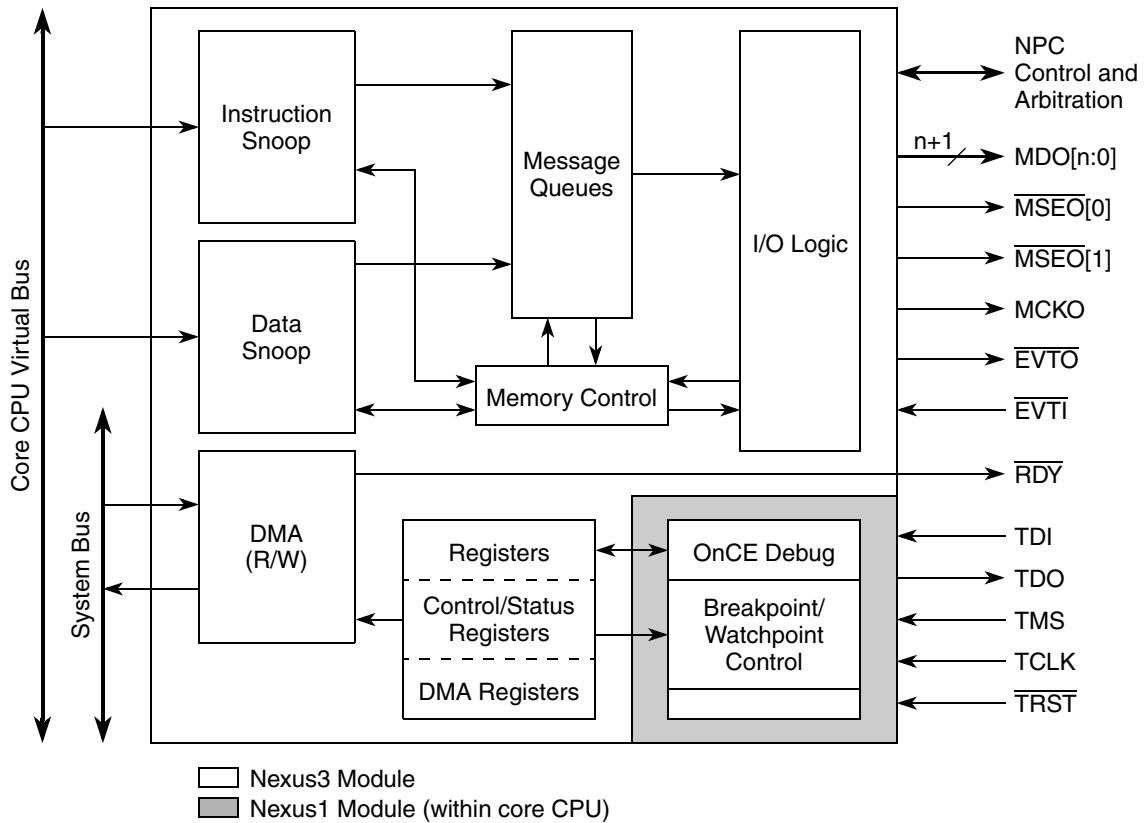

Figure 24-13. e200z6 Nexus3 Functional Block Diagram

24.10.3 Overview

Table 24-18 contains a set of terms and definitions associated with the NZ6C3 module.

Table 24-18. Terms and Definitions

Term	Description
IEEE®-ISTO 5001	Consortium and standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE® 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Client	A functional block on an embedded processor which requires development visibility and controllability. Examples are a central processing unit (CPU) or an intelligent peripheral.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
JTAG Compliant	Device complying to IEEE® 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG instruction register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG data register (DR) scan.
Nexus1	The e200z6 (OnCE) debug module. This module integrated with each e200z6 processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE®-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
Standard	The phrase 'according to the standard' is used to indicate according to the IEEE®-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A data or instruction breakpoint which does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A watchpoint message is also generated.

24.10.4 Features

The NZ6C3 module is compliant with Class 3 of the IEEE®-ISTO 5001-2003 standard. The following features are implemented:

- Program trace via branch trace messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data trace via data write messaging (DWM) and data read messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership trace via ownership trace messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An ownership trace message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor registers and memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint messaging via the auxiliary pins.
- Watchpoint trigger enable of program and/or data trace messaging.
- Higher speed data input/output via the auxiliary port.
- Auxiliary interface for higher data input/output
 - Configurable (minimum and maximum) message data out pins (**nex_mdo[n:0]**)
 - One or two message start/end out pins (**nex_mseo_b[1:0]**)
 - One read/write ready pin (**nex_rdy_b**) pin
 - One watchpoint-event pin (**nex_evto_b**)
 - One event-in pin (**nex_evti_b**)
 - One MCKO (message clock out) pin
- Registers for program trace, data trace, ownership trace and watchpoint trigger.
- All features controllable and configurable via the JTAG port.

24.10.5 Enabling Nexus3 Operation

The Nexus module is enabled by loading a single instruction (ACCESS_AUX_TAP_ONCE, as shown in [Table 24-4](#)) into the JTAGC instruction register (IR), and then loading the corresponding OnCE OCMD register with the NEXUS3_ACCESS instruction (refer to [Table 24-5](#)). For the e200z6 Class 3 Nexus module, the OCMD value is 0b00_0111_1100. After it is enabled, the module will be ready to accept control input via the JTAG pins.

Refer to [Section 24.4, “NDI Functional Description”](#) for more information.

The Nexus module is disabled when the JTAG state machine reaches the test-logic-reset state. This state can be reached by the assertion of the JCOMP pin or by cycling through the state machine using the TMS pin. The Nexus module will also be disabled if a power-on-reset (POR) event occurs. If the Nexus3 module

is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins MDO[n:0], MSEO[1:0], MCKO. Nexus registers will not be available for reads or writes.

24.10.6 TCODEs Supported by NZ6C3

The Nexus3 pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE®-ISTO 5001-2003 standard defines a set of public messages. The NZ6C3 module supports the public TCODEs seen in [Table 24-19](#). Each message contains multiple packets transmitted in the order shown in the table.

Table 24-19. Public TCODEs Supported by NZ6C3

Message Name	Packet Size (bits)		Packet Name	Packet Type	Packet Description
	Min	Max			
Debug Status	6	6	TCODE	Fixed	TCODE number = 0 (0x00)
	4	4	SRC	Fixed	Source processor identifier
	8	8	STATUS	Fixed	Debug status register (DS[31:24])
Ownership Trace Message	6	6	TCODE	Fixed	TCODE number = 2 (0x02)
	4	4	SRC	Fixed	Source processor identifier
	32	32	PROCESS	Fixed	Task/Process ID tag
Program Trace - Direct Branch Message ¹	6	6	TCODE	Fixed	TCODE number = 3 (0x03)
	4	4	SRC	Fixed	Source processor identifier
	1	8	I-CNT	Variable	Number of sequential instructions executed since last taken branch
Program Trace - Indirect Branch Message ¹	6	6	TCODE	Fixed	TCODE number = 4 (0x04)
	4	4	SRC	Fixed	Source processor identifier
	1	8	I-CNT	Variable	Number of sequential instructions executed since last taken branch
	1	32	U-ADDR	Variable	Unique part of target address for taken branches/exceptions
Data Trace - Data Write Message	6	6	TCODE	Fixed	TCODE number = 5 (0x05)
	4	4	SRC	Fixed	Source processor identifier
	3	3	DSIZ	Fixed	Data size (Refer to Table 24-23)
	1	32	U-ADDR	Variable	Unique portion of the data write address
	1	64	DATA	Variable	Data write values (refer to Section 24.11.13 , "Data Trace," for details)

Table 24-19. Public TCODEs Supported by NZ6C3 (continued)

Message Name	Packet Size (bits)		Packet Name	Packet Type	Packet Description
	Min	Max			
Data Trace - Data Read Message	6	6	TCODE	Fixed	TCODE number = 6 (0x06)
	4	4	SRC	Fixed	Source processor identifier
	3	3	DSIZ	Fixed	Data size (Refer to Table 24-23)
	1	32	U-ADDR	Variable	Unique portion of the data read address
	1	64	DATA	Variable	Data read values (refer to Section 24.11.13 , “Data Trace,” for details)
Error Message	6	6	TCODE	Fixed	TCODE number = 8 (0x08)
	4	4	SRC	Fixed	Source processor identifier
	5	5	ECODE	Fixed	Error code
Program Trace - Direct Branch Message w/ Sync ¹	6	6	TCODE	Fixed	TCODE number = 11 (0x0B)
	4	4	SRC	Fixed	Source processor identifier
	1	8	I-CNT	Variable	Number of sequential instructions executed since last taken branch
	1	32	F-ADDR	Variable	Full target address (leading zeros truncated)
Program Trace - Indirect Branch Message w/ Sync ¹	6	6	TCODE	Fixed	TCODE number = 12 (0x0C)
	4	4	SRC	Fixed	Source processor identifier
	1	8	I-CNT	Variable	Number of sequential instructions executed since last taken branch
	1	32	F-ADDR	Variable	Full target address (leading zeros truncated)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	Fixed	TCODE number = 13 (0x0D)
	4	4	SRC	Fixed	Source processor identifier
	3	3	DSZ	Fixed	Data size (refer to Table 24-23)
	1	32	F-ADDR	Variable	Full access address (leading zeros truncated)
	1	64	DATA	Variable	Data write values (refer to Section 24.11.13 , “Data Trace,” for details)
Data Trace - Data Read Message w/ Sync	6	6	TCODE	Fixed	TCODE number = 14 (0x0E)
	4	4	SRC	Fixed	Source processor identifier
	3	3	DSZ	Fixed	Data size (Refer to Table 24-23)
	1	32	F-ADDR	Variable	Full access address (leading zeros truncated)
	1	64	DATA	Variable	Data read values (refer to Section 24.11.13 , “Data Trace,” for details)

Table 24-19. Public TCODEs Supported by NZ6C3 (continued)

Message Name	Packet Size (bits)		Packet Name	Packet Type	Packet Description
	Min	Max			
Watchpoint Message	6	6	TCODE	Fixed	TCODE number = 15 (0x0F)
	4	4	SRC	Fixed	Source processor identifier
	4	4	WPHIT	Fixed	Number indicating watchpoint sources
Resource Full Message	6	6	TCODE	Fixed	TCODE number = 27 (0x1B)
	4	4	SRC	Fixed	Source processor identifier
	4	4	RCODE	Fixed	Resource code (Refer to RCODE values in Table 24-22) - indicates which resource is the cause of this message
	1	32	RDATA	Variable	Branch / predicate instruction history (refer to Section 24.11.12.1, "Branch Trace Messaging (BTM)")
Program Trace - Indirect Branch History Message	6	6	TCODE	Fixed	TCODE number = 28 (0x1C) (refer to footnote 1 below)
	4	4	SRC	Fixed	Source processor identifier
	1	8	I-CNT	Variable	Number of sequential instructions executed since last taken branch
	1	32	U-ADDR	Variable	Unique part of target address for taken branches/exceptions
	1	32	HIST	Variable	Branch / predicate instruction history (refer to Section 24.11.12.1, "Branch Trace Messaging (BTM)")
Program Trace - Indirect Branch History Message w/ Sync	6	6	TCODE	Fixed	TCODE number = 29 (0x1D) (refer to footnote 1 below)
	4	4	SRC	Fixed	Source processor identifier
	1	8	I-CNT	Variable	Number of sequential instructions executed since last taken branch
	1	32	F-ADDR	Variable	Full target address (leading zero (0) truncated)
	1	32	HIST	Variable	Branch / predicate instruction history (refer to Section 24.11.12.1, "Branch Trace Messaging (BTM)")

Table 24-19. Public TCODEs Supported by NZ6C3 (continued)

Message Name	Packet Size (bits)		Packet Name	Packet Type	Packet Description
	Min	Max			
Program Trace - Program Correlation Message	6	6	TCODE	Fixed	TCODE number = 33 (0x21)
	4	4	SRC	Fixed	Source processor identifier
	4	4	EVCODE	Fixed	Event correlated w/ program flow (Refer to Table 24-22)
	1	8	I-CNT	Variable	Number of sequential instructions executed since last taken branch
	1	32	HIST	Variable	Branch / predicate instruction history (refer to Section 24.11.12.1, "Branch Trace Messaging (BTM)")

¹ The user can select between the two types of program trace. The advantages for each are discussed in [Section 24.11.12.1, "Branch Trace Messaging \(BTM\)"](#). If the branch history method is selected, the shaded TCODEs above will not be messaged out.

[Table 24-20](#) shows the error code encodings used when reporting an error via the Nexus3 Error Message.

Table 24-20. Error Code Encoding (TCODE = 8)

Error Code (ECODE)	Description
00000	Ownership trace overrun
00001	Program trace overrun
00010	Data trace overrun
00011	Read/write access error
00101	Invalid access opcode (Nexus register unimplemented)
00110	Watchpoint overrun
00111	(Program trace or data trace) and ownership trace overrun
01000	(Program trace or data trace or ownership trace) and watchpoint overrun
01001–10111	Reserved
11000	BTM lost due to collision w/ higher priority message
11001–11111	Reserved

Table 24-21 shows the encodings used for resource codes for certain messages.

Table 24-21. RCODE values (TCODE = 27)

Resource Code (RCODE)	Description	Resource Data (RDATA)
0000	Program Trace Instruction Counter overflow (reached 255 and was reset)	0xFF
0001	Program Trace, Branch / Predicate Instruction History. This type of packet is terminated by a stop bit set to 1 after the last history bit.	Branch History. This type of packet is terminated by a stop bit set to a 1 after the last history bit.

Table 24-22 shows the event code encodings used for certain messages.

Table 24-22. Event Code Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only) ¹
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101–1101	Reserved for future functionality
1110	Entry into a VLE page from a non-VLE page
1111	Entry into a non-VLE page from a VLE page

¹ The device enters Low Power Mode when the Nexus stall mode is enabled (NZ6C3_DC1[OVC]=0b011) and a trace message is in danger of over-flowing the Nexus queue.

Table 24-23 shows the data trace size encodings used for certain messages.

Table 24-23. Data Trace Size Encodings (TCODE = 5, 6, 13, 14)

DTM Size Encoding	Transfer Size
000	Byte
001	Halfword (2 bytes)
010	Word (4 bytes)
011	Doubleword (8 bytes)
100	String (3 bytes)
101–111	Reserved

NOTE

Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in [Section 24.11.12.1, “Branch Trace Messaging \(BTM\)”](#). If the Branch History method is selected, the shaded TCODES above will not be messaged out.

24.11 NZ6C3 Memory Map/Register Definition

This section describes the NZ6C3 programmer’s model. NZ6C3 registers are accessed using the JTAG/OnCE port in compliance with IEEE® 1149.1. Refer to [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE”](#) for details on NZ6C3 register access.

NOTE

NZ6C3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE®-ISTO 5001 standard.

[Table 24-24](#) details the register map for the NZ6C3 module.

Table 24-24. NZ6C3 Memory Map

Access Opcode	Register Name	Register Description	Read Address	Write Address
0x0001	CSC	Client select control ¹	0x0002	—
Refer to NPC	PCR	Port configuration register ¹	—	—
0x0002	DC1	Development control 1	0x0004	0x0005
0x0003	DC2	Development control 2	0x0006	0x0007
0x0004	DS	Development status	0x0008	—
0x0007	RWCS	Read/write access control/status	0x000E	0x000F
0x0009	RWA	Read/write access address	0x0012	0x0013
0x000A	RWD	Read/write access data	0x0014	0x0015
0x000B	WT	Watchpoint trigger	0x0016	0x0017
0x000D	DTC	Data trace control	0x001A	0x001B
0x000E	DTSA1	Data trace start address 1	0x001C	0x001D
0x000F	DTSA2	Data trace start address 2	0x001E	0x001F
0x0012	DTEA1	Data trace end address 1	0x0024	0x0025
0x0013	DTEA2	Data trace end address 2	0x0026	0x0027
0x0014– 0x003F	—	Reserved	0x0028– 0x007E	0x0029– 0x007F

¹ The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level Nexus3 controller (NPC), not in the NZ6C3 module. The device's CSC register is readable through Nexus3, but the PCR is shown for reference only.

24.11.0.1 Port Configuration Register (PCR)

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

Figure 24-14. Port Configuration Register

Table 24-25. Port Configuration Register Fields

PCR[31]	OPC	OPC — Output Port Mode Control 0 = Reduced Port Mode configuration (minimum # nex_mdo[n:0] pins) 1 = Full Port Mode configuration (max# nex_mdo[n:0] pins defined by SOC)
PCR[30]	—	Reserved for future functionality
PCR[29]	MCK_EN	MCK_EN — MCKO Clock enable 0 = nex_mcko is disabled 1 = nex_mcko is enabled
PCR[28:26]	MCK_DIV	MCK_DIV — MCKO Clock Divide Ratio (read note that follows this table) 000 = nex_mcko is 1x processor clock frequency. 001 = nex_mcko is 1/2x processor clock frequency. 010 = Reserved (defaults to 1/2x processor clock frequency.) 011 = nex_mcko is 1/4x processor clock frequency. 100–110 = Reserved (defaults to 1/2x processor clock frequency.) 111 = nex_mcko is 1/8x processor clock frequency.
PCR[25:0]	—	Reserved for future functionality

NOTE

The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the Zen Nexus3 module is the only Nexus module, these registers are not implemented and the Zen Nexus3 defined Development Control Register 1 (DC1) is used to control Nexus port functionality.

24.11.1 Development Control Register 1, 2 (DC1, DC2)

The development control registers are used to control the basic development features of the NZ6C3 module. Development control register 1 is shown in [Figure 24-15](#) and its fields are described in [Table 24-26](#).

23–0	Reserved.

NOTE

The EOC bits in DC1 must be programmed to trigger $\overline{EVT0}$ on watchpoint occurrence for the EWC bits to have any effect.

24.11.2 Development Status Register (DS)

The development status register is used to report system debug status. When debug mode is entered or exited, or an e200z6-defined low power mode is entered, a debug status message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg: 0x0004

Access: R/O

24–0	Reserved.

24.11.3 Read/Write Access Control/Status (RWCS)

The read write access control/status register provides control for read/write access. Read/write access provides DMA-like access to memory-mapped resources on the system bus either while the processor is halted, or during runtime. The RWCS register also provides read/write access status information as shown in [Table 24-30](#).

Table 24-29. RWCS Field Description (continued)

Field	Description
1 ERR	Read/write access error. Refer to Table 24-30 .
0 DV	Read/write access data valid. Refer to Table 24-30 .

[Table 24-30](#) details the status bit encodings.

Table 24-30. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read access has not completed	Write access completed without error	0	0
Read access error has occurred	Write access error has occurred	1	0
Read access completed without error	Write access has not completed	0	1
Not allowed	Not allowed	1	1

24.11.4 Read/Write Access Address (RWA)

The read/write access address register provides the system bus address to be accessed when initiating a read or a write access.

Figure 24-19. Read/Write Access Address Register (RWA)

24.11.5 Read/Write Access Data (RWD)

The read/write access data register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Figure 24-20. Read/Write Access Data Register (RWD)

24.11.6 Watchpoint Trigger Register (WT)

The watchpoint trigger register allows the watchpoints defined within the e200z6 Nexus1 logic to trigger actions. These watchpoints can control program and/or data trace enable and disable. The WT bits can be used to produce an address related ‘window’ for triggering trace messages.

Nexus Reg: 0x000B

Access: R/W

Table 24-31. WT Field Descriptions (continued)

Field	Description
22–20 DTE[2:0]	Data trace end control. 000 Trigger disabled 001 Use watchpoint #0 (IAC1 from Nexus1) 010 Use watchpoint #1 (IAC2 from Nexus1) 011 Use watchpoint #2 (IAC3 from Nexus1) 100 Use watchpoint #3 (IAC4 from Nexus1) 101 Use watchpoint #4 (DAC1 from Nexus1) 110 Use watchpoint #5 (DAC2 from Nexus1) 111 Use watchpoint #6 or #7 (DCNT1 or DCNT2 from Nexus1)
19–0	Reserved.

NOTE

The WT bits will only control program/data trace if the TM bits in the development control register 1 (DC1) have not already been set to enable program and data trace, respectively.

24.11.7 Data Trace Control Register (DTC)

The data trace control register controls whether DTM messages are restricted to reads, writes, or both for a user programmable address range. There are two data trace channels controlled by the DTC for the Nexus3 module. Each channel can also be programmed to trace data accesses or instruction accesses.

Nexus Reg: 0x000D

Access: R/W

Figure 24-22. Data Trace Control Register (DTC)

Table 24-32 details the data trace control register fields.

Table 24-32. DTC Field Description

Field	Description
31–30 RWT1[1:0]	Read/write trace 1. 00 No trace enabled X1 Enable data read trace 1X Enable data write trace
29–28 RWT2[1:0]	Read/write trace 2. 00 No trace enabled X1 Enable data read trace 1X Enable data write trace
27–8	Reserved.

Table 24-32. DTC Field Description (continued)

Field	Description
7 RC1	Range control 1. 0 Condition trace on address within range 1 Condition trace on address outside of range
6 RC2	Range control 2 0 Condition trace on address within range 1 Condition trace on address outside of range
5–4	Reserved.
3 DI1	Data access/instruction access trace 1. 0 Condition trace on data accesses 1 Condition trace on instruction accesses
2 DI2	Data access/instruction access trace 2 0 Condition trace on data accesses 1 Condition trace on instruction accesses
1–0	Reserved.

24.11.8 Data Trace Start Address Registers 1 and 2 (DTSA_n)

The data trace start address registers define the start addresses for each trace channel.

Figure 24-23. Data Trace Start Address Register 1 (DTSA1)

Figure 24-24. Data Trace Start Address Register 2 (DTSA2)

24.11.9 Data Trace End Address Registers 1 and 2 (DTEAn)

The data trace end address registers define the end addresses for each trace channel.

Figure 24-25. Data Trace End Address Register 1 (DTEA1)

Figure 24-26. Data Trace End Address Register 2 (DTEA2)

Table 24-33 illustrates the range that will be selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 24-33. Data Trace—Address Range Options

Programmed Values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA -> <- DTEA
DTSA < DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range—no trace
DTSA = DTEA	N/A	Invalid range—no trace

NOTE

DTSA must be less than DTEA to guarantee correct data write/read traces.
Data trace ranges are exclusive of the DTSA and DTEA addresses.

24.11.10 NZ6C3 Register Access via JTAG / OnCE

Access to Nexus3 register resources is enabled by loading a single instruction (ACCESS_AUX_TAP_ONCE) into the JTAGC instruction register (IR), and then loading the corresponding OnCE OCMD register with the NEXUS3_ACCESS instruction (refer to Table 24-5). For the NZ6C3 module, the OCMD value is 0b00_0111_1100.

After the ACCESS_AUX_TAP_ONCE instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus3 registers according to the register map in Table 24-24.

Reading/writing of a NZ6C3 register then requires two (2) passes through the data-scan (DR) path of the JTAG state machine (refer to 24.11.17).

1. The first pass through the DR selects the NZ6C3 register to be accessed by providing an index (refer to [Table 24-24](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG data register (DR). This register has the following format:

Nexus Register Index:	Selected from values in Table 24-24
Read/Write (R/W):	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, lsb first.
 - a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the capture-DR state.
 - b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the update-DR state.

24.11.11 Ownership Trace

This section details the ownership trace features of the NZ6C3 module.

24.11.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

24.11.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an ownership trace message (OTM). The e200z6 processor contains a Power Architecture Book E defined process ID register within the CPU.

The process ID register is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The process ID register value can be accessed using the **mf spr/mt spr** instructions. Please refer to the *e200z6 PowerPC™ Core Reference Manual* for more details on the process ID register.

There is one condition that will cause an ownership trace message: When new information is updated in the OTR register or process ID register by the e200z6 processor, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow.

Ownership trace information is messaged out in the following format:

Figure 24-27. Ownership Trace Message Format

24.11.11.3 OTM Error Messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. After it is emptied, an error message will be queued. The error encoding will indicate which types of messages attempted to be queued while the FIFO was being emptied.

If only an OTM message attempts to enter the queue while it is being emptied, the error message will incorporate the OTM only error encoding (00000). If both OTM and either BTM or DTM messages attempt to enter the queue, the error message will incorporate the OTM and (program or data) trace error encoding (00111). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message will incorporate error encoding (01000).

NOTE

The OVC bits within the DC1 register can be set to delay the CPU to alleviate (but not eliminate) potential overrun situations.

Error information is messaged out in the following format (refer to [Table 24-20](#)):

Figure 24-28. Error Message Format

24.11.11.4 OTM Flow

Ownership trace messages are generated when the operating system writes to the e200z6 process ID register or the memory mapped ownership trace register.

The following flow describes the OTM process:

1. The process ID register is a system control register. It is internal to the e200z6 processor and can be accessed by using PPC instructions **mtspr** and **mfspr**. The contents of this register are replicated on the pins of the processor and connected to Nexus.
2. OTR/process ID register reads do not cause ownership trace messages to be transmitted by the NZ6C3 module.
3. If the periodic OTM message counter expires (after 255 queued messages without an OTM), an OTM is sent using the latched data from the previous OTM or process ID register write.

24.11.12 Program Trace

This section details the program trace mechanism supported by NZ6C3 for the e200z6 processor. Program trace is implemented via branch trace messaging (BTM) as per the Class 3 IEEE®-ISTO 5001-2003 standard definition. Branch trace messaging for e200z6 processors is accomplished by snooping the e200z6 virtual address bus (between the CPU and MMU), attribute signals, and CPU status.

24.11.12.1 Branch Trace Messaging (BTM)

Traditional branch trace messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception. Direct (or indirect) branches not taken are counted as sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address.

Branch history messaging facilitates program trace by providing the following information:

- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last predicate instruction, taken indirect branch, or exception, the unique portion of the branch target address or exception vector address, as well as a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Certain instructions (**evsel**) generate a pair of predicate bits which are both reported as consecutive bits in the history field.

24.11.12.1.1 e200z6 Indirect Branch Message Instructions (Power Architecture Book E)

Table 24-34 shows the types of instructions and events which cause indirect branch messages or branch history messages to be encoded.

Table 24-34. Indirect Branch Message Sources

Source of Indirect Branch Message	Instructions
Taken branch relative to a register value	bcctr, bcctrl, bclr, bclrl
System call / trap exceptions taken	sc, tw, twi
Return from interrupts / exceptions	rfi, rfc1, rfd1

24.11.12.1.2 e200z6 Direct Branch Message Instructions (Power Architecture Book E)

Table 24-35 shows the types of instructions which will cause direct branch messages or will toggle a bit in the instruction history buffer to be messaged out in a resource full message or branch history message.

Table 24-35. Direct Branch Message Sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions	b, ba, bl, bla, bc, bca, bcl, bcla
Instruction synchronize	isync

24.11.12.1.3 BTM Using Branch History Messages

Traditional BTM messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch history messaging solves this problem by providing a predicated instruction history field in each indirect branch message. Each bit in the history represents a predicated instruction or direct branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the direct branch was not taken. Certain instructions (**evsel**) generate a pair of predicate bits which are both reported as consecutive bits in the history field.

Branch history messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

24.11.12.1.4 BTM Using Traditional Program Trace Messages

Based on the PTM bit in the DC register (DC[PTM]), program tracing can utilize either branch history messages (DC[PTM] = 1) or traditional direct/indirect branch messages (DC[PTM] = 0).

Branch history will save bandwidth and keep consistency between methods of program trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the indirect branch history message, other types of messages may enter the FIFO between branch history messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

24.11.12.2 BTM Message Formats

The e200z6 Nexus3 module supports three types of traditional BTM messages—direct, indirect, and synchronization messages. It supports two types of branch history BTM messages—indirect branch history, and indirect branch history with synchronization messages. Debug status messages and error messages are also supported.

24.11.12.2.1 Indirect Branch Messages (History)

Indirect branches include all taken branches whose destination is determined at run time, interrupts and exceptions. If DC[PTM] is set, indirect branch information is messaged out in the following format:

Figure 24-29. Indirect Branch Message (History) Format

24.11.12.2.2 Indirect Branch Messages (Traditional)

If DC[PTM] is cleared, indirect branch information is messaged out in the following format:

Figure 24-30. Indirect Branch Message Format

24.11.12.2.3 Direct Branch Messages (Traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

Figure 24-31. Direct Branch Message Format

NOTE

When DC[PTM] is set, direct branch messages will not be transmitted. Instead, each direct branch or predicated instruction will toggle a bit in the history buffer.

24.11.12.2.4 Resource Full Messages

The resource full message is used in conjunction with the branch history messages. The resource full message is generated when the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next branch trace message that is not a resource full message.

The current value of the history buffer is transmitted as part of the resource full message. This information can be concatenated by the tool with the branch/predicate history information from subsequent messages to obtain the complete branch history for a message. The internal history value is reset by this message, and the I-CNT value is reset as a result of a bit being added to the history buffer.

Figure 24-32. Resource Full Message Format

24.11.12.2.5 Debug Status Messages

NOTE

Debug Status Messages (DSMs) are enabled if the Nexus module is enabled.

Debug status messages report low power mode and debug status. Entering/exiting debug mode as well as entering a low power mode will trigger a debug status message.

Debug status information is sent out in the following format:

Figure 24-33. Debug Status Message Format

24.11.12.2.6 Program Correlation Messages

Program correlation messages are used to correlate events to the program flow that may not be associated with the instruction stream. To maintain accurate instruction tracing information when entering debug mode or a CPU low power mode (where tracing may be disabled), this message is sent upon entry into one of these two modes and includes the instruction count and branch history. Program correlation is messaged out in the following format:

Figure 24-34. Program Correlation Message Format

24.11.12.2.7 BTM Overflow Error Messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. After it is emptied, an error message will be queued. The error encoding will indicate which types of messages attempted to be queued while the FIFO was being emptied.

If only a program trace message attempts to enter the queue while it is being emptied, the error message will incorporate the program trace only error encoding (00001). If both OTM and program trace messages attempt to enter the queue, the error message will incorporate the OTM and program trace error encoding (00111). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message will incorporate error encoding (01000).

NOTE

The OVC bits within the DC1 register can be set to delay the CPU to alleviate (but not eliminate) potential overrun situations.

Error information is messaged out in the following format:

Figure 24-35. Error Message Format

24.11.12.2.8 Program Trace Synchronization Messages

A program trace direct/indirect branch with sync message is messaged via the auxiliary port (provided program trace is enabled) for the following conditions (refer to [Table 24-36](#)):

- Initial program trace message upon the first direct/indirect branch after exit from system reset or whenever program trace is enabled
- Upon direct/indirect branch after returning from a CPU low power state
- Upon direct/indirect branch after returning from debug mode
- Upon direct/indirect branch after occurrence of queue overrun (can be caused by any trace message), provided program trace is enabled
- Upon direct/indirect branch after the periodic program trace counter has expired indicating 255 *without-sync* program trace messages have occurred since the last *with-sync* message occurred
- Upon direct/indirect branch after assertion of the event in (EVTI) pin if the EIC bits within the DC1 register have enabled this feature
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred between branches
- Upon direct/indirect branch after a BTM message was lost due to an attempted access to a secure memory location.
- Upon direct/indirect branch after a BTM message was lost due to a collision entering the FIFO between the BTM message and either a watchpoint message or an ownership trace message

If the NZ6C3 module is enabled at reset, a EVTI assertion initiates a program trace direct/indirect branch with sync message (if program trace is enabled) upon the first direct/indirect branch. The format for program trace direct/indirect branch with sync messages is as follows:

Figure 24-36. Direct/Indirect Branch with Sync Message Format

The formats for program trace direct/indirect branch with sync. messages and indirect branch history with sync. messages are as follows:

Figure 24-37. Indirect Branch History with Sync. Message Format

Exception conditions that result in program trace synchronization are summarized in [Table 24-36](#).

Table 24-36. Program Trace Exception Summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (JCOMP), queue pointers, counters, state machines, and registers within the NZ6C3 module are reset. Upon the first branch out of system reset (if program trace is enabled), the first program trace message is a direct/indirect branch with sync. message.
Program Trace Enabled	The first program trace message (after program trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next direct/indirect branch will be converted to a direct/indirect branch with sync. message.
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. After it is emptied, an error message will be queued. The error encoding will indicate which types of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a direct/indirect branch with sync. message.
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 program trace messages have been queued. A direct/indirect branch with sync. message is queued. The periodic program trace message counter then resets.
Event In	If the Nexus module is enabled, an EVTI assertion initiates a direct/indirect branch with sync. message upon the next direct/indirect branch (if program trace is enabled and the EIC bits of the DC1 register have enabled this feature).
Sequential Instruction Count Overflow	When the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A program trace direct/indirect branch with sync. message is queued upon execution of the next branch.
Attempted Access to Secure Memory	For devices which implement security, any attempted branch to secure memory locations will temporarily disable program trace & cause the corresponding BTM to be lost. The following direct/indirect branch will queue a direct/indirect branch with sync. message. The count value within this message will be inaccurate since the re-enable of program trace is not necessarily aligned on an instruction boundary.

Table 24-36. Program Trace Exception Summary (continued)

Exception Condition	Exception Handling
Collision Priority	All messages have the following priority: WPM -> OTM -> BTM -> DTM. A BTM message which attempts to enter the queue at the same time as a watchpoint message or ownership trace message will be lost. An error message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a direct/indirect branch with sync. message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch which did not generate a message due to the collision.

24.11.12.3 BTM Operation

24.11.12.3.1 Enabling Program Trace

Both types of branch trace messaging can be enabled in one of two ways:

- Setting the TM field of the DC1 register to enable program trace (DC1[TM])
- Using the PTS field of the WT register to enable program trace on watchpoint hits (e200z6 watchpoints are configured within the CPU)

24.11.12.3.2 Relative Addressing

The relative address feature is compliant with the IEEE[®]-ISTO 5001-2003 standard recommendations, and is designed to reduce the number of bits transmitted for addresses of indirect branch messages.

The address transmitted is relative to the target address of the instruction which triggered the previous indirect branch (or sync) message. It is generated by XOR'ing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

Previous address (A1) = 0x0003FC01, New address (A2) = 0x0003F365

<p>Message Generation:</p> <p>A1 = 0000 0000 0000 0011 1111 1100 0000 0001 A2 = 0000 0000 0000 0011 1111 0011 0110 0101</p> <p>$A1 \oplus A2 = 0000\ 0000\ 0000\ 0000\ 0000\ 1111\ 0110\ 0100$</p> <p>Address Message (M1) = 1111 0110 0100</p> <p>Address Re-creation:</p> <p>$A1 \oplus M1 = A2$ A1 = 0000 0000 0000 0011 1111 1100 0000 0001 M1 = 0000 0000 0000 0000 0000 1111 0110 0100 <hr/> A2 = 0000 0000 0000 0011 1111 0011 0110 0101</p>

Figure 24-38. Relative Address Generation and Re-creation

24.11.12.3.3 Branch/Predicate Instruction History (HIST)

If DC[PTM] is set, BTM messaging will use the branch history format. The branch history (HIST) packet in these messages provides a history of direct branch execution used for reconstructing the program flow. This packet is implemented as a left-shifting shift register. The register is always pre-loaded with a value of one (1). This bit acts as a stop bit so that the development tools can determine which bit is the end of the history information. The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer on a taken branch (condition or unconditional) and on any instruction whose predicate condition executed as true. A value of zero (0) is shifted into the history buffer on any instruction whose predicate condition executed as false as well as on branches not taken. This will include indirect as well as direct branches not taken. For the **evsel** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

24.11.12.3.4 Sequential Instruction Count (I-CNT)

The I-CNT packet, is present in all BTM messages. For traditional branch messages, I-CNT represents the number of sequential instructions, or non-taken branches in between direct/indirect branch messages.

For branch history messages, I-CNT represents the number of instructions executed since the last taken/non-taken direct branch, last taken indirect branch or exception. Not taken indirect branches are considered sequential instructions and cause the instruction count to increment. I-CNT also represents the number of instructions executed since the last predicate instruction.

The sequential instruction counter overflows when its value reaches 255. The next BTM message will be converted to a synchronization type message.

24.11.12.3.5 Program Trace Queuing

NZ6C3 implements a message queue. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

NOTE

If multiple trace messages need to be queued at the same time, Watchpoint Messages will have the highest priority (WPM → OTM → BTM → DTM).

24.11.12.4 Program Trace Timing Diagrams

Figure 24-39. Program Trace (MDO = 12)—Indirect Branch Message (Traditional)

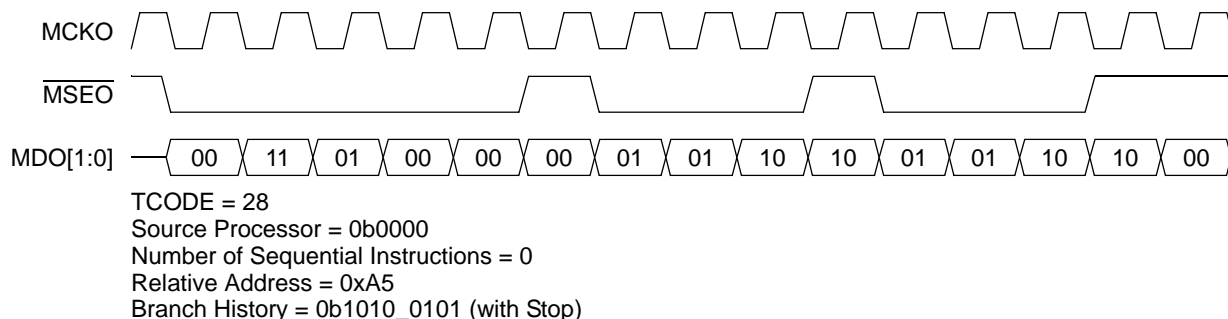

Figure 24-40. Program Trace (MDO = 2)—Indirect Branch Message (History)

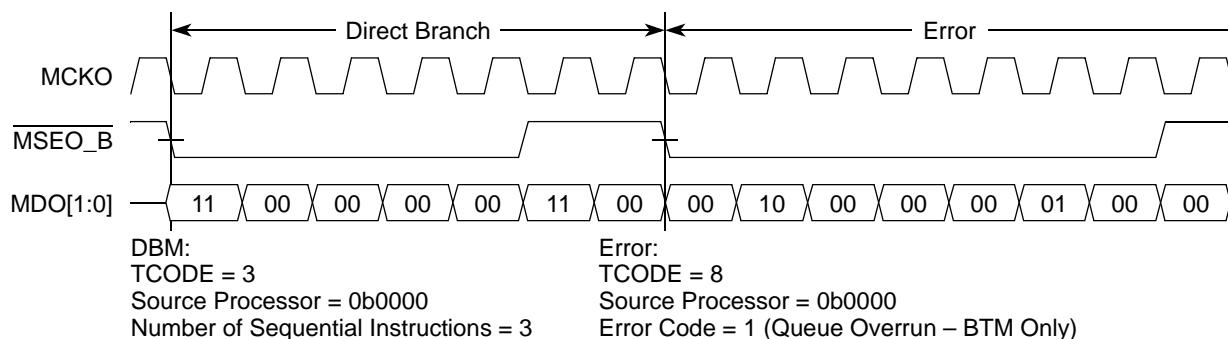

Figure 24-41. Program Trace—Direct Branch (Traditional) and Error Messages

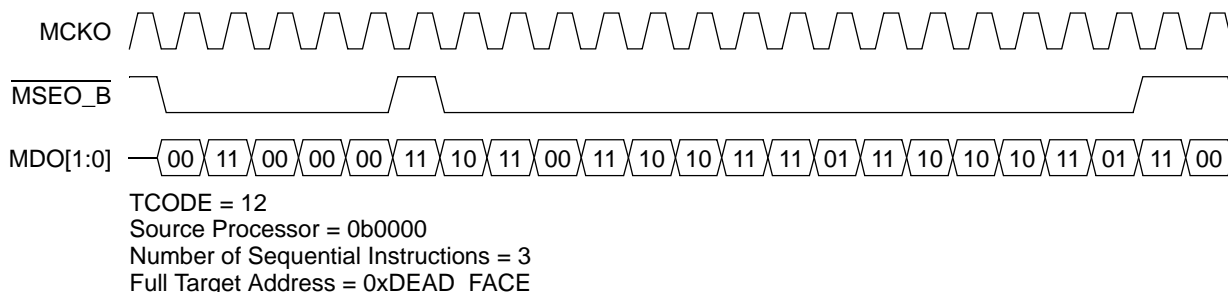

Figure 24-42. Program Trace—Indirect Branch with Sync. Message

24.11.13 Data Trace

This section deals with the data trace mechanism supported by the NZ6C3 module. Data trace is implemented via data write messaging (DWM) and data read messaging (DRM), as per the IEEE®-ISTO 5001-2003 standard.

24.11.13.1 Data Trace Messaging (DTM)

Data trace messaging for e200z6 is accomplished by snooping the e200z6 virtual data bus (between the CPU and MMU), and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NZ6C3 module traces all data access that meet the selected range and attributes.

NOTE

Data trace is only performed on the e200z6 virtual data bus. This allows for data visibility for the incorporated data cache. Only e200z6 CPU initiated accesses will be traced. No DMA accesses to the NXDM system bus will be traced.

Data trace messaging can be enabled in one of two ways:

- Setting the TM field of the DC1 register to enable data trace (DC1[TM]).
- Using WT[DTS] to enable data trace on watchpoint hits (e200z6 watchpoints are configured within the Nexus1 module)

24.11.13.2 DTM Message Formats

The Nexus3 module supports five types of DTM messages: data write, data read, data write synchronization, data read synchronization and error messages.

24.11.13.2.1 Data Write Messages

The data write message contains the data write value and the address of the write access, relative to the previous data trace message. Data write message information is messaged out in the following format:

Figure 24-43. Data Write Message Format

24.11.13.2.2 Data Read Messages

The data read message contains the data read value and the address of the read access, relative to the previous data trace message. Data read message information is messaged out in the following format:

Figure 24-44. Data Read Message Format

NOTE

For the e200z6 based CPU, the doubleword encoding (data size = 0b000) will indicate a doubleword access and will be sent out as a single data trace message with a single 64-bit data value.

24.11.13.2.3 DTM Overflow Error Messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. After it is emptied, an error message will be queued. The error encoding will indicate which types of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message will incorporate the data trace only error encoding (00010). If both OTM and data trace messages attempt to enter the queue, the error message will incorporate the OTM and data trace error encoding (00111). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message will incorporate error encoding (01000).

NOTE

The OVC bits within the DC1 register can be set to delay the CPU to alleviate (but not eliminate) potential overrun situations.

Error information is messaged out in the following format:

Figure 24-45. Error Message Format

24.11.13.2.4 Data Trace Synchronization Messages

A data trace write/read with sync. message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (refer to [Table 24-37](#)):

- Initial data trace message after exit from system reset or whenever data trace is enabled
- Upon exiting debug mode
- After occurrence of queue overrun (can be caused by any trace message), provided data trace is enabled
- After the periodic data trace counter has expired indicating 255 *without-sync* data trace messages have occurred since the last *with-sync* message occurred
- Upon assertion of the event in (EVTI) pin, the first data trace message will be a synchronization message if the EIC bits of the DC1 register have enabled this feature
- Upon data trace write/read after the previous DTM message was lost due to an attempted access to a secure memory location

- Upon data trace write/read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any of the following: watchpoint message, ownership trace message, or branch trace message

Data trace synchronization messages provide the full address (without leading zeros) and insure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent data messages, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with sync. messages is as follows:

Figure 24-46. Data Write/Read with Sync. Message Format

Exception conditions that result in data trace synchronization are summarized in [Table 24-37](#).

Table 24-37. Data Trace Exception Summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (JCOMP), queue pointers, counters, state machines, and registers within the NZ6C3 module are reset. If data trace is enabled, the first data trace message is a data write/read with sync. message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message will be converted to a data write/read with sync. message.
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. After it is emptied, an error message will be queued. The error encoding will indicate which types of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a data write/read with sync. message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with sync. message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a EVTI assertion initiates a data trace write/read with sync. message upon the next data write/read (if data trace is enabled and the EIC bits of the DC1 register have enabled this feature).
Attempted Access to Secure Memory	For devices which implement security, any attempted read or write to secure memory locations will temporarily disable data trace & cause the corresponding DTM to be lost. A subsequent read/write will queue a data trace read/write with sync. message.
Collision Priority	All messages have the following priority: WPM → OTM → BTM → DTM. A DTM message which attempts to enter the queue at the same time as a watchpoint message or ownership trace message or branch trace message will be lost. A subsequent read/write will queue a data trace read/write with sync. message.

24.11.13.3 DTM Operation

24.11.13.3.1 DTM Queueing

NZ6C3 implements a message queue for DTM messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

NOTE

If multiple trace messages need to be queued at the same time, watchpoint messages will have the highest priority (WPM → OTM → BTM → DTM).

24.11.13.3.2 Relative Addressing

The relative address feature is compliant with the IEEE®-ISTO 5001-2003 standard recommendations, and is designed to reduce the number of bits transmitted for addresses of data trace messages. Refer to [Section 24.11.12.3.2, “Relative Addressing](#) for details.

24.11.13.3.3 Data Trace Windowing

Data write/read messages are enabled via the RWT1(2) field in the data trace control register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA registers and by the RC1(2) field in the DTC. All e200z6 initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

24.11.13.3.4 Data Access/Instruction Access Data Tracing

The Nexus3 module is capable of tracing both instruction access data or data access data. Each trace window can be configured for either type of data trace by setting the DI1(2) field within the data trace control register for each DTM channel.

24.11.13.3.5 e200z6 Bus Cycle Special Cases

Table 24-38. e200z6 Bus Cycle Cases

Special Case	Action
e200z6 bus cycle aborted	Cycle ignored
e200z6 bus cycle with data error (\overline{TEA})	Data Trace Message discarded
e200z6 bus cycle completed without error	Cycle captured & transmitted
e200z6 bus cycle initiated by NZ6C3	Cycle ignored
e200z6 bus cycle is an instruction fetch	Cycle ignored
e200z6 bus cycle accesses misaligned data (across 64-bit boundary)—both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & 2 DTM's transmitted (refer to Note)

Table 24-38. e200z6 Bus Cycle Cases (continued)

Special Case	Action
e200z6 bus cycle accesses misaligned data (across 64-bit boundary)—1st transaction within data trace range; 2nd transaction out of data trace range	1st cycle captured and transmitted; 2nd cycle ignored
e200z6 bus cycle accesses misaligned data (across 64-bit boundary)—1st transaction out of data trace range; 2nd transaction within data trace range	1st cycle ignored; 2nd cycle capture and transmitted

NOTE

For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses. If both accesses are within the data trace range, two DTMs will be sent: one with a size encoding indicating the size of the original access (that is, word), and one with a size encoding for the portion which crossed the boundary (that is, 3-byte).

NOTE

An STM to the cache’s store buffer within the data trace range will initiate a DTM message. If the corresponding memory access causes an error, a checkstop condition will occur. The debug/development tool should use this indication to invalidate the previous DTM.

24.11.13.4 Data Trace Timing Diagrams (Eight MDO Configuration)

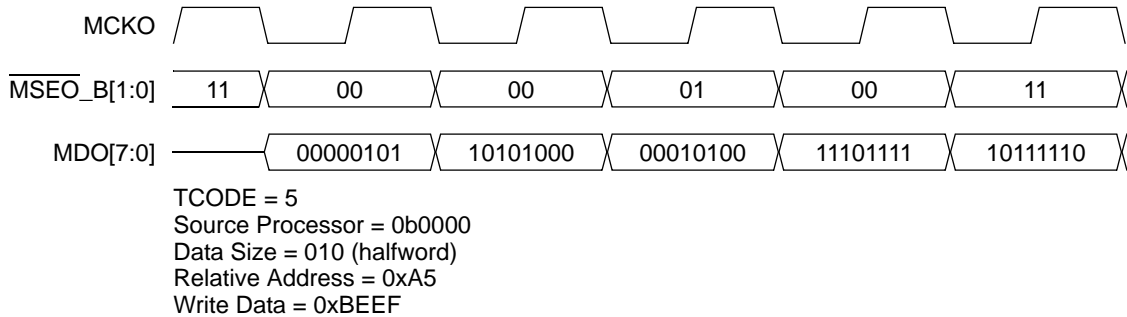

Figure 24-47. Data Trace—Data Write Message

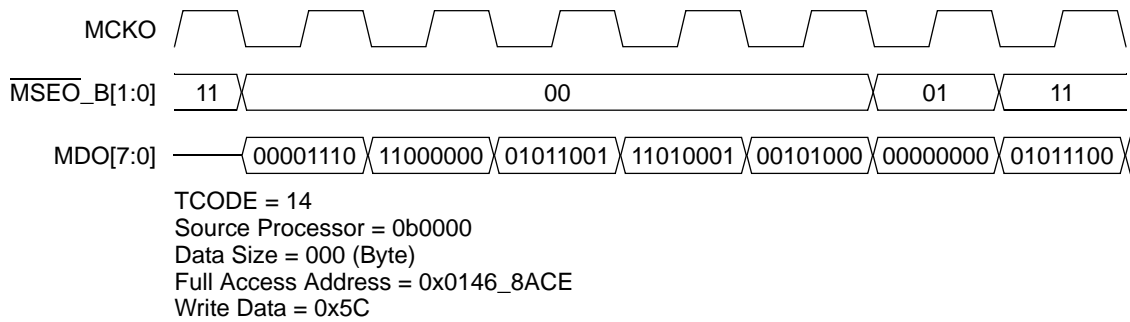

Figure 24-48. Data Trace—Data Read with Sync Message

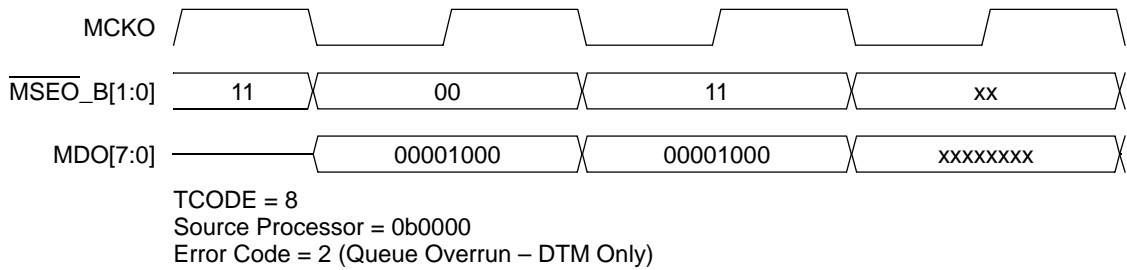

Figure 24-49. Error Message (Data Trace only encoded)

24.11.14 Watchpoint Support

This section details the watchpoint features of the NZ6C3 module.

24.11.14.1 Overview

The NZ6C3 module provides watchpoint messaging via the auxiliary pins, as defined by the IEEE®-ISTO 5001-2003 standard.

NZ6C3 is not compliant with Class4 breakpoint/watchpoint requirements defined in the standard. The breakpoint/watchpoint control register is not implemented.

24.11.14.2 Watchpoint Messaging

Enabling watchpoint messaging is done by setting the watchpoint enable bit in the DC1 register. Setting the individual watchpoint sources is supported through the e200z6 Nexus1 module. The e200z6 Nexus1 module is capable of setting multiple address and/or data watchpoints. Please refer to the e200z6 Core Reference Manual for more information on watchpoint initialization.

When these watchpoints occur, a watchpoint event signal from the Nexus1 module causes a message to be sent to the queue to be messaged out. This message includes the watchpoint number indicating which watchpoint caused the message.

The occurrence of any of the e200z6 defined watchpoints can be programmed to assert the event out \overline{EVTO} pin for one period of the output clock (MCKO).

Watchpoint information is messaged out in the following format:

Figure 24-50. Watchpoint Message Format.

Table 24-39. Watchpoint Source Encoding

Watchpoint Source (8 bits)	Watchpoint Description
00000001	e200z6 Watchpoint #0 (IAC1 from Nexus1)
00000010	e200z6 Watchpoint #1 (IAC2 from Nexus1)
00000100	e200z6 Watchpoint #2 (IAC3 from Nexus1)
00001000	e200z6 Watchpoint #3 (IAC4 from Nexus1)
00010000	e200z6 Watchpoint #4 (DAC1 from Nexus1)
00100000	e200z6 Watchpoint #5 (DAC2 from Nexus1)
01000000	e200z6 Watchpoint #6 (DCNT1 from Nexus1)
10000000	e200z6 Watchpoint #7 (DCNT2 from Nexus1)

24.11.14.3 Watchpoint Error Message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. After it is emptied, an error message will be queued. The error encoding will indicate which types of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message will incorporate the watchpoint only error encoding (00110). If an OTM and/or program trace and/or data trace message also attempts to enter the queue while it is being emptied, the error message will incorporate error encoding (01000).

NOTE

The OVC bits within the DC1 register can be set to delay the CPU to alleviate (but not eliminate) potential overrun situations.

Error information is messaged out in the following format (refer to [Table 24-20](#)):

Figure 24-51. Error Message Format

24.11.14.4 Watchpoint Timing Diagram (2 MDO and 1 MSEO Configuration)

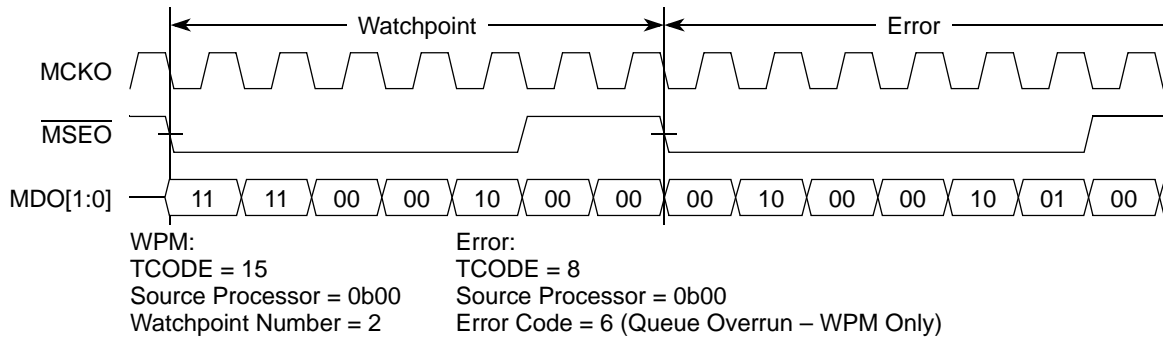

Figure 24-52. Watchpoint Message and Watchpoint Error Message

24.11.15 NZ6C3 Read/Write Access to Memory-Mapped Resources

The read/write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The read/write mechanism supports single as well as block reads and writes to e200z6 system bus resources.

The NZ6C3 module is capable of accessing resources on the e200z6 system bus, with multiple configurable priority levels. Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the read/write access control/status register (RWCS), as well as the read/write access address (RWA) and read/write access data registers (RWD).

Using the read/write access registers (RWCS/RWA/RWD), memory-mapped e200z6 system bus resources can be accessed through NZ6C3. The following subsections describe the steps which are required to access memory-mapped resources.

NOTE

Read/write access can only access memory mapped resources when system reset is de-asserted.

Misaligned accesses are NOT supported in the e200z6 Nexus3 module.

24.11.15.1 Single Write Access

1. Initialize the read/write access address register (RWA) through the access method outlined in [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE”](#) using the Nexus register index of 0x9 (refer to [Table 24-24](#)). Configure as follows:
 - Write Address -> 0xnwnnnnnn (write address)
2. Initialize the read/write access control/status register (RWCS) through the access method outlined in [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE,”](#) using the Nexus Register Index of 0x7 (refer to [Table 24-24](#)). Configure the bits as follows:
 - Access Control RWCS[AC] -> 0b1 (to indicate start access)
 - Map Select RWCS[MAP] -> 0b000 (primary memory map)
 - Access Priority RWCS[PR] -> 0b00 (lowest priority)
 - Read/Write RWCS[RW] -> 0b1 (write access)
 - Word Size RWCS[SZ] -> 0b0xx (32-bit, 16-bit, 8-bit)
 - Access Count RWCS[CNT] -> 0x0000 or 0x0001 (single access)

NOTE

Access count RWCS[CNT] of 0x0000 or 0x0001 will perform a single access.

3. Initialize the read/write access data register (RWD) through the access method outlined in [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE,”](#) using the Nexus register index of 0xA (refer to [Table 24-24](#)). Configure as follows:
 - Write Data -> 0xnwnnnnnnn (write data)
4. The NZ6C3 module will then arbitrate for the system bus and transfer the data value from the data buffer RWD register to the memory mapped address in the read/write access address register (RWA). When the access has completed without error (ERR=1'b0), NZ6C3 asserts the RDY pin and clears the DV bit in the RWCS register. This indicates that the device is ready for the next access.

NOTE

Only the RDY pin as well as the DV and ERR bits within the RWCS provide read/write access status to the external development tool.

24.11.15.2 Block Write Access (Non-Burst Mode)

1. For a non-burst block write access, follow Steps 1, 2, and 3 outlined in [Section 24.11.15.1, “Single Write Access to initialize the registers,”](#) but using a value greater than one (0x1) for the RWCS[CNT] field.
2. The NZ6C3 module will then arbitrate for the system bus and transfer the first data value from the RWD register to the memory mapped address in the read/write access address register (RWA). When the transfer has completed without error (ERR = 0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. Nexus will then assert the RDY pin. This indicates that the device is ready for the next access.

3. Repeat step 3 in [Section 24.11.15.1, “Single Write Access”](#) until the internal CNT value is zero (0). When this occurs, the DV bit within the RWCS will be cleared to indicate the end of the block write access.

24.11.15.3 Block Write Access (Burst Mode)

1. For a burst block write access, follow Steps 1 and 2 outlined in [Section 24.11.15.1, “Single Write Access”](#) to initialize the registers, using a value of four (doublewords) for the CNT field and a RWCS[SZ] field indicating 64-bit access.
2. Initialize the burst data buffer (read/write access data register) through the access method outlined in [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE,”](#) using the Nexus register Index of 0xA (refer to [Table 24-24](#)).
3. Repeat step 2 until all doubleword values are written to the buffer.

NOTE

The data values must be shifted in 32-bits at a time lsb first (that is, doubleword write = two word writes to the RWD).

4. The Nexus module will then arbitrate for the system bus and transfer the burst data values from the data buffer to the system bus beginning from the memory mapped address in the read/write access address register (RWA). For each access within the burst, the address from the RWA register is incremented to the next doubleword size (specified in the SZ field) modulo the length of the burst, and the number from the CNT field is decremented.
5. When the entire burst transfer has completed without error (ERR = 0), NZ6C3 will then assert the RDY pin, and the DV bit within the RWCS will be cleared to indicate the end of the block write access.

NOTE

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access (burst or non-burst). The original values can be read by the external development tool at any time.

24.11.15.4 Single Read Access

1. Initialize the read/write access address register (RWA) through the access method outlined in [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE,”](#) using the Nexus register index of 0x9 (refer to [Table 24-24](#)). Configure as follows:
 - Read Address → 0xn timer (read address)
2. Initialize the read/write access control/status register (RWCS) through the access method outlined in [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE,”](#) using the Nexus register index of 0x7 (refer to [Table 24-24](#)). Configure the bits as follows:
 - Access Control RWCS[AC] → 0b1 (to indicate start access)
 - Map Select RWCS[MAP] → 0b000 (primary memory map)
 - Access Priority RWCS[PR] → 0b00 (lowest priority)
 - Read/Write RWCS[RW] → 0b0 (read access)

- Word Size RWCS[SZ] → 0b0xx (32-bit, 16-bit, 8-bit)
- Access Count RWCS[CNT] → 0x0000 or 0x0001 (single access)

NOTE

Access Count (CNT) of 0x0000 or 0x0001 will perform a single access.

3. The NZ6C3 module will then arbitrate for the system bus and the read data will be transferred from the system bus to the RWD register. When the transfer is completed without error (ERR = 0), Nexus asserts the RDY pin and sets the DV bit in the RWCS register. This indicates that the device is ready for the next access.
4. The data can then be read from the read/write access data register (RWD) through the access method outlined in [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE,”](#) using the Nexus register index of 0xA (refer to [Table 24-24](#)).

NOTE

Only the RDY pin as well as the DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

24.11.15.5 Block Read Access (Non-Burst Mode)

1. For a non-burst block read access, follow Steps 1 and 2 outlined in [Section 24.11.15.4, “Single Read Access”](#) to initialize the registers, but using a value greater than one (0x1) for the CNT field in the RWCS register.
2. The NZ6C3 module will then arbitrate for the system bus and the read data will be transferred from the system bus to the RWD register. When the transfer has completed without error (ERR=0b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. Nexus will then assert the RDY pin. This indicates that the device is ready for the next access.
3. The data can then be read from the read/write access data register (RWD) through the access method outlined in [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE,”](#) using the Nexus register index of 0xA (refer to [Table 24-24](#)).
4. Repeat steps 3 and 4 in [Section 24.11.15.4, “Single Read Access”](#) until the CNT value is zero (0). When this occurs, the DV bit within the RWCS is set to indicate the end of the block read access.

24.11.15.6 Block Read Access (Burst Mode)

1. For a burst block read access, follow Steps 1 and 2 outlined in [Section 24.11.15.4, “Single Read Access”](#) to initialize the registers, using a value of four (doublewords) for the CNT field and an RWCS[SZ] field indicating 64-bit access.
2. The NZ6C3 module will then arbitrate for the system bus and the burst read data will be transferred from the system bus to the data buffer (RWD register). For each access within the burst, the address from the RWA register is incremented to the next doubleword (specified in the SZ field) and the number from the CNT field is decremented.
3. When the entire burst transfer has completed without error (ERR = 0), Nexus will then assert the RDY pin and the DV bit within the RWCS will be set to indicate the end of the block read access.

4. The data can then be read from the burst data buffer (read/write access data register) through the access method outlined in [Section 24.11.10, “NZ6C3 Register Access via JTAG / OnCE,”](#) using the Nexus register index of 0xA (refer to [Table 24-24](#)).
5. Repeat step 3 until all doubleword values are read from the buffer.

NOTE

The data values must be shifted out 32-bits at a time lsb first (that is, doubleword read = two word reads from the RWD).

NOTE

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access (burst or non-burst). The original values can be read by the external development tool at any time.

24.11.15.7 Error Handling

The NZ6C3 module handles various error conditions as follows:

24.11.15.7.1 System Bus Read/Write Error

All address and data errors that occur on read/write accesses to the e200z6 system bus will return a transfer error. If this occurs:

1. The access is terminated without re-trying (AC bit is cleared).
2. The ERR bit in the RWCS register is set.
3. The error message is sent (TCODE = 8) indicating read/write error.

24.11.15.7.2 Access Termination

The following cases are defined for sequences of the read/write protocol that differ from those described in the above sections:

1. If the AC bit in the RWCS register is set to start read/write accesses and invalid values are loaded into the RWD and/or RWA, then a system bus access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS register is written, then the original block access is terminated at the boundary of the nearest completed access.
 - a) If the RWCS is written with the AC bit set, the next read/write access will begin and the RWD can be written to/ read from.
 - b) If the RWCS is written with the AC bit cleared, the read/write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

24.11.15.8 Read/Write Access Error Message

The read/write access error message is sent out when an system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

Figure 24-53. Error Message Format

24.11.16 Examples

The following are examples of program trace and data trace messages.

Table 24-40 illustrates an example indirect branch message with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Table 24-40. Indirect Branch Message Example (12 MDO / 2 MSEO)

Clock	MDO[11:0]												MSEO[1:0]		State
	11	10	9	8	7	6	5	4	3	2	1	0			
0	X	X	X	X	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	I1	I0	S3	S2	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	0	0	0	0	I5	I4	I3	I2	0	1	End Packet
3	0	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	X	X	S3	S2	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start of Next Message

Table 24-41 illustrates an example of direct branch message with 12 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of instructions (variable)

Table 24-41. Direct Branch Message Example (12 MDO / 2 MSEO)

Clock	MDO[11:0]												MSEO[1:0]		State
	11	10	9	8	7	6	5	4	3	2	1	0			
0	X	X	X	X	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	I1	I0	S3	S2	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	0	0	0	0	0	0	I3	I2	1	1	End Packet/End Message
3	X	X	X	X	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start of Next Message

Table 24-42 an example data write message with 12 MDO and two MSEO configuration.

T0, A0, D0 are the least significant bits (LSB) where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable - 8, 16 or 32-bit)

Table 24-42. Direct Write Message Example (12 MDO and 2 MSEO)

Clock	MDO[11:0]												MSEO[1:0]		State
	11	10	9	8	7	6	5	4	3	2	1	0			
0	X	X	X	X	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	Z1	Z0	S3	S2	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	0	0	0	A3	A2	A1	A0	Z2	0	1	End Packet
3	X	X	X	X	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/End Message

24.11.17 IEEE® 1149.1 (JTAG) RD/WR Sequences

This section contains example JTAG/OnCE sequences used to access resources.

24.11.17.1 JTAG Sequence for Accessing Internal Nexus Registers

Table 24-43. Accessing Internal Nexus3 Registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus command register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (read/write) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)

Table 24-43. Accessing Internal Nexus3 Registers via JTAG/OnCE (continued)

Step #	TMS Pin	Description
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus command register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR → EXIT1-DR (msb of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete - Nexus controller to reg. select state)

24.11.17.2 JTAG Sequence for Read Access of Memory-Mapped Resources

Table 24-44. Accessing Memory-Mapped Resources (Reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to read/write access address register (RWA)
2	37	Write RWA (initialize starting read address—data input on TDI)
3	13	Nexus Command = write to read/write control/status register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value—data input on TDI)
5	—	Wait for falling edge of RDY pin
6	13	Nexus Command = read read/write access data register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

24.11.17.3 JTAG Sequence for Write Access of Memory-Mapped Resources

Table 24-45. Accessing Memory-Mapped Resources (Writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to read/write access control/status register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value—data input on TDI)
3	13	Nexus Command = write to read/write address register (RWA)
4	37	Write RWA (initialize starting write address—data input on TDI)
5	13	Nexus Command = read read/write access data register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of RDY pin
8	—	If CNT > 0, go back to Step #5

24.12 Nexus Crossbar eDMA Interface (NXDM)

The third module of the device NDI interface is the e200z6 eDMA Nexus module (NXDM) which is compliant with the Class 3 defined data trace feature of the IEEE®-ISTO 5001-2003 standard. The NXDM can be programmed to trace data accesses for the eDMA module on the system bus. This eDMA module as well as the Nexus module are components of the e200z6 platform. All output messages and register accesses are compliant with the protocol defined in the IEEE®-ISTO 5001 standard.

NOTE

Throughout this section references are made to the auxiliary port and its specific signals, such as MCKO, MSEO[1:0], MDO[12:0] and others. In actual use the device NPC module arbitrates the access of the single auxiliary port. To simplify the description of the function of the NXDM module, the interaction of the NPC is omitted and the behavior described as if the module has its own dedicated auxiliary port. The auxiliary port function is fully described in [Section 24.2, “External Signal Description.”](#)

24.12.1 Block Diagram

Figure 24-54 shows a block diagram of the NXDM.

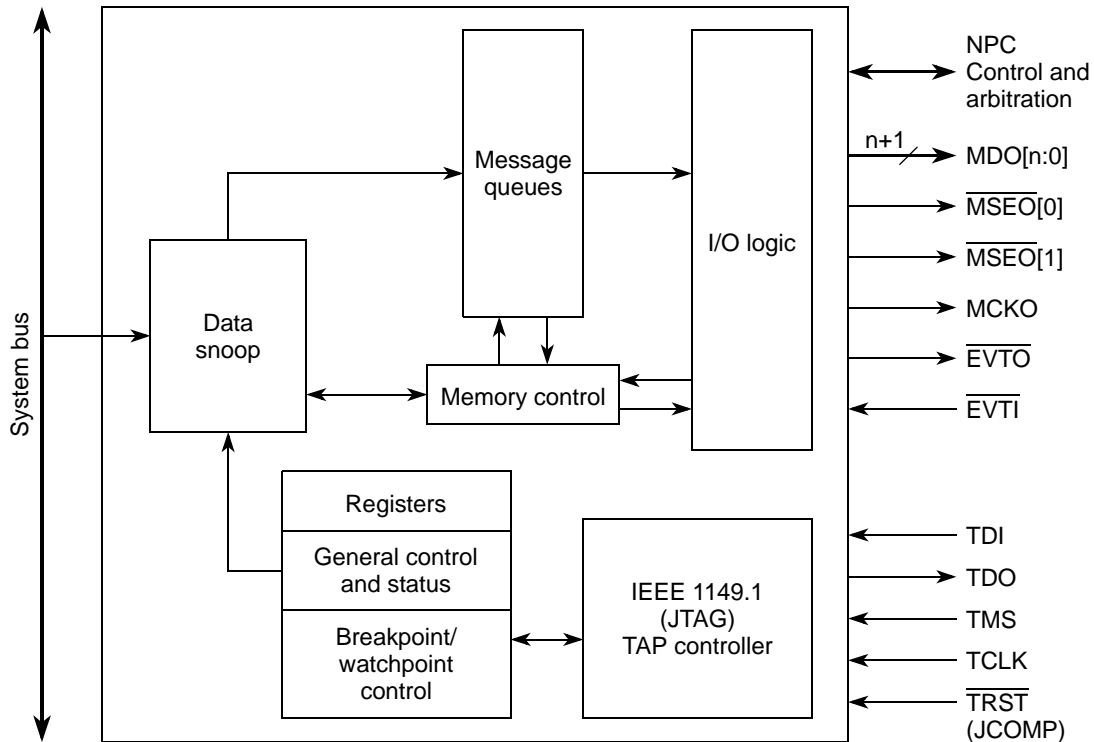

Figure 24-54. NXDM Block Diagram

24.12.2 Features

Features include the following:

- Data trace via data write messaging (DWM) and data read messaging (DRM). This provides the capability for the development tool to trace reads and/or writes through the eDMA module to (selected) internal memory resources.
- Watchpoint messaging via the auxiliary pins.
- Watchpoint trigger enable of data trace messaging (DTM).
- Registers for data trace, watchpoint generation, and watchpoint trigger.
- All features controllable and configurable via the JTAG port.
- Power management.
 - Low power design
 - Dynamic power management of FIFOs and control logic

24.13 External Signal Description

The NXDM module uses the same pins and pin protocol as defined in [Section 24.2, “External Signal Description.”](#)

24.13.1 Rules for Output Messages

The NXDM module observe the same rules for output messages as the NPC. Refer to [Section 24.7.2.2.1, “Rules of Messages.”](#)

24.13.2 Auxiliary Port Arbitration

The NXDM module arbitrate for the shared Nexus port. This arbitration is handled by the NPC (Refer to [Section 24.5, “Nexus Port Controller \(NPC\)”](#)) based on prioritized requests from the NXDM, and the other Nexus clients sharing the port.

24.14 NXDM Programmers Model

This section describes the programmers model. Nexus registers are accessed using the JTAG port in compliance with IEEE® 1149.1. Refer to [Chapter 23, “IEEE 1149.1 Test Access Port Controller \(JTAGC\)”](#) and [Section 24.7.2.3, “IEEE, 1149.1-2001 \(JTAG\) TAP”](#) for details on Nexus register access.

24.14.1 NXDM Nexus Register Map

Table 24-46. NXDM Register Map

Nexus Register	Nexus Access Opcode	Read/Write	Read Address	Write Address
Client Select Control (CSC) ¹	0x1	R	0x02	–
Port Configuration Register (PCR) ¹	Refer to NPC	R/W	–	–
Development Control 1 (DC1 _n)	0x2	R/W	0x04	0x05
Development Control 2 (DC2 _n)	0x3	R/W	0x05	0x06
Watchpoint Trigger (WT _n)	0xB	R/W	0x16	0x17
Data Trace Control (DTC _n)	0xD	R/W	0x1A	0x1B
Data Trace Start Address 1 (DTSA1 _n)	0xE	R/W	0x1C	0x1D
Data Trace Start Address 2 (DTSA2 _n)	0xF	R/W	0x1E	0x1F
Data Trace End Address 1 (DTEA1 _n)	0x12	R/W	0x24	0x25
Data Trace End Address 2 (DTEA2 _n)	0x13	R/W	0x26	0x27
Breakpoint/Watchpoint Control Register 1 (BWC1 _n)	0x16	R/W	0x2C	0x2D
Breakpoint/Watchpoint Control Register 2 (BWC2 _n)	0x17	R/W	0x2E	0x2F
Breakpoint/Watchpoint Address Register 1 (BWA1 _n)	0x1E	R/W	0x3C	0x3D
Breakpoint/Watchpoint Address Register 2 (BWA2 _n)	0x1F	R/W	0x3E	0x3F
Reserved	0x20–0x3F	–	0x40–0x7E	0x41–0x7F

¹ The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level Nexus3 controller (NPC), not in the NXDM module. The device's CSC register is readable through Nexus3; the PCR is shown for reference only.

24.14.2 NXDM Registers

Detailed register definitions for the NXDM implementation are as follows:

24.14.2.1 Development Control Registers (DC1 and DC2)

The development control registers control the basic development features of the NXDM module.

Figure 24-55. Development Control Register 1 (DC1)

Table 24-47. DC1 Field Description

Field	Description
31 OPC ¹	Output port mode control 0 Reduced port mode configuration 1 Full port mode configuration
30–29 MCK_DIV ¹	MCK_DIV - nexus message clock divide ratio 00 MCKO is 1x system bus clock frequency. 01 MCKO is 1/2x system bus clock frequency. 10 MCKO is 1/4x system bus clock frequency. 11 MCKO is 1/8x system bus clock frequency.
28–27 EOC	$\overline{\text{EVTO}}$ control 00 $\overline{\text{EVTO}}$ upon occurrence of watchpoint (internal or external) 01 $\overline{\text{EVTO}}$ upon entry into system-level debug mode (ipg_debug) 1X Reserved
26–25	Reserved, read as 0.
24 WEN	Watchpoint trace enable 0 Watchpoint messaging disabled 1 Watchpoint messaging enabled.
23–5	Reserved, read as 0.
4–3 EIC	$\overline{\text{EVTI}}$ control 00 $\overline{\text{EVTI}}$ for synchronization (Data Trace) 01 Reserved 10 $\overline{\text{EVTI}}$ disabled for this module 11 Reserved
2–0 TM	Trace mode 000 No Trace 1XX Reserved X1X Data trace enabled XX1 Reserved

¹ The output port mode control bit (OPC) and MCKO divide bits (MCK_DIV) are shown for clarity. These functions are controlled globally by the NPC port control register (PCR).

Figure 24-56. Development Control Register 2 (DC2)

Table 24-48. DC2 Field Description

Field	Description
31–24 EWC ¹	\overline{EVTO} Watchpoint Configuration 00000000 = No watchpoints trigger \overline{EVTO} 1XXXXXXXX = Reserved X1XXXXXXXX = Reserved XX1XXXXXX = Reserved XXX1XXXXX = Reserved XXXX1XXX = Internal watchpoint #1 triggers \overline{EVTO} XXXXX1XX = Internal watchpoint #2 triggers \overline{EVTO} XXXXXX1X = Reserved XXXXXXX1 = Reserved
23–0	Reserved, read as 0.

¹ The EOC bits in DC1 must be programmed to trigger \overline{EVTO} on watchpoint occurrence for the EWC bits to have any effect.

24.14.2.2 Watchpoint Trigger Register (WT)

The watchpoint trigger register allows the watchpoints defined internally to the NXDM modules to trigger actions. These watchpoints can control data trace enable and disable. The WT bits can be used to produce an address related window for triggering trace messages.

Figure 24-57. Watchpoint Trigger Register (WT)

Table 24-49. WT Field Description

Field	Description
31–26	Reserved, read as 0.
25–23 DTS	DTS - Data trace start control 000 Trigger disabled 001-100 Reserved 101 Use internal watchpoint #1 (BWA1 register) 110 Use internal watchpoint #2 (BWA2 register) 111 Reserved

Table 24-49. WT Field Description (continued)

Field	Description
22–20 DTE	DTE - Data trace end control 000 Trigger disabled 001-100 Reserved 101 Use internal watchpoint #1 (BWA1 register) 110 Use internal watchpoint #2 (BWA2 register) 111 Reserved
19–0	Reserved, read as 0.

NOTE

The WT bits ONLY enable data trace if the tm bits within the development control register (DC) have not already been set to enable data trace.

24.14.2.3 Data Trace Control Register (DTC)

The data trace control register controls whether DTM Messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXDM module.

Figure 24-58. Data Trace Control Register (DTC)

Table 24-50. DTC Field Description

Bit	Description
31–30 RWT1	Read/write trace 1 00 No trace messages generated X1 Enable data read trace 1X Enable data write trace
29–28 RWT2	Read/write trace 2 00 No trace messages generated X1 Enable data read trace 1X Enable data write trace
27–8	Reserved, read as 0.
7 RC1	Range control 1 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
6 RC2	Range control 2 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
5–0	Reserved, read as 0.

24.14.2.4 Data Trace Start Address Registers 1 and 2 (DTSA1 and DTSA2)

The data trace start address registers define the start addresses for each trace channel.

Figure 24-59. Data Trace Start Address Registers (DTSA1, DTSA2)

24.14.2.5 Data Trace End Address Registers 1 and 2 (DTEA1 and DTEA2)

The data trace end address registers define the end addresses for each trace channel.

Figure 24-60. Data Trace End Address Registers (DTEA1, DTEA2)

Table 24-51 below illustrates the range that will be selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 24-51. Data Trace - Address Range Options

Programmed Values	Range Control Bit Value	Range Selected
DTSA < or = DTEA	0	DTSA-> <-DTEA
DTSA < or = DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range, no trace

NOTE

DTSA must be less than (or equal to) DTEA to guarantee correct data write/read traces. When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses will be traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA will not be traced.

24.14.2.6 Breakpoint / Watchpoint Control Register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls attributes for generation of NXDM watchpoint number 1.

Figure 24-61. Break / Watchpoint Control Register 1 (BWC1)

Table 24-52. BWC1 Field Description

Field	Description
31–30 BWE1	Breakpoint/watchpoint #1 enable 00 Internal Nexus watchpoint #1 disabled 01–10 Reserved 11 Internal Nexus watchpoint #1 enabled

14–0	Reserved, read as 0.

24.14.2.8 Breakpoint/Watchpoint Address Registers 1 and 2 (BWA1 and BWA2)

The breakpoint/watchpoint address registers are compared with bus addresses to generate internal watchpoints.

Figure 24-63. Breakpoint / Watchpoint Address Registers (BWA1, BWA2)

24.14.2.9 Unimplemented Registers

Unimplemented registers are those with client select and index value combinations other than those listed in [Table 24-46](#). For unimplemented registers, the NXDM module will drive TDO to zero during the “SHIFT-DR” state. It will also transmit an error message with the invalid access opcode encoding.

24.14.2.10 Programming Considerations ($\overline{\text{RESET}}$)

If Nexus3 register configuration is to occur during system reset (as opposed to debug mode), all NXDM configuration should be completed between the negation of JCOMP and system reset de-assertion, after the JTAG DID register has been read by the tool.

24.14.2.11 IEEE® 1149.1 (JTAG) Test Access Port

The NXDM module uses the IEEE® 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. Refer to [Chapter 23, “IEEE 1149.1 Test Access Port Controller \(JTACC\)”](#) for more information on the JTAG interface.

The NXDM modules implements a 4-bit instruction register (IR). The valid instructions and method for register access are outlined in [Section 24.7.2.3, “IEEE, 1149.1-2001 \(JTAG\) TAP.”](#)

24.14.2.11.1 NXDM JTAG DID Register

This JTAG DID register that is included in the NXDM module provides key development attributes to the development tool concerning the NXDM block. The register is accessed through the standard JTAG IR/DR paths. Refer to [Chapter 22, “Voltage Regulator Controller \(VRC\) and POR Module.”](#)

Figure 24-64. NXDM JTAG DID Register

Table 24-54. NXDM JTAG DID Field Descriptions

Field	Description
31–28 PRN ¹	Embedded part revision number (0x0)
27–22 DC	Freescale design center ID number (0x1F)
21–12 PIN	NXDM module part identification number, defines the features set. (0x60)
11–1 MIC	Manufacturer identity code 0x00E Freescale
0	Fixed per JTAG 1149.1 1 Always set

¹ The revision number is initially 0 and could change in the future.

24.14.2.11.2 Enabling the NXDM TAP Controller

Assertion of a power-on-reset signal or assertion of the JCOMP pin resets all TAP controllers on the device. Upon exit from the test-logic-reset state, the IR value is loaded with the JTAG DID. When the NXDM TAP is accessed, this information will help the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, and so forth.

24.14.2.11.3 NXDM Register Access via JTAG

Access to Nexus register resources is enabled by loading a single instruction (NEXUS_ACCESS) into the JTAG Instruction Register (IR). This IR is part of the IEEE® 1149.1 TAP controller within the NXDM modules. Refer to [Section 23.4.4, “JTAGC Instructions.”](#)

After the JTAG NEXUS_ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in [Table 24-46](#).

Reading/writing of a Nexus register then requires two (2) passes through the data-scan (DR) path of the JTAG state machine (refer to [Chapter 23, “IEEE 1149.1 Test Access Port Controller \(JTAGC\)”](#)).

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (refer to [Table 24-46](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG data register (DR). This register has the following format:

Figure 24-65. JTAG DR for NEXUS Register Access

Table 24-55. DR Read/Write Encoding

Nexus Register Index	
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, lsb first.
 - a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the capture-DR state.
 - b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the update-DR state.

24.14.3 Functional Description

24.14.4 Enabling NXDM Operation

The NXDM module is enabled by loading a single instruction (ACCESS_AUX_TAP_DMA as shown in [Table 24-4](#)) into the JTAG instruction register (IR), and then loading the corresponding OnCE OCMD register with the NEXUS_ACCESS instruction (refer to [Table 24-5](#)). After it is enabled, the module will be ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the test-logic-reset state. This state can be reached by the assertion of the JCOMP pin or by cycling through the state machine using the TMS pin. The Nexus module will also be disabled if a power-on reset (POR) event occurs.

If the NXDM module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (MDO[11:0], MSEO[1:0], MCKO). Nexus registers will not be available for reads or writes.

24.14.5 TCODEs Supported by NXDM

The NXDM pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE®-ISTO 5001-2003 standard defines a set of public messages. The NXDM block currently support the public TCODEs seen in [Table 24-56](#).

Table 24-56. Public TCODEs Supported

Message Name	Packet Size Bits		Packet Name	Packet Type	Packet Description
	Min	Max			
Data Trace - Data Write Message	6	6	TCODE	Fixed	TCODE number = 5
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	3	3	DSZ	Fixed	Data size (refer to Table 24-58)
	1	32	U-ADDR	Variable	Unique portion of the data write value
	1	64	DATA	Variable	Data write value
Data Trace - Data Read Message	6	6	TCODE	Fixed	TCODE number = 6
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	3	3	DSZ	Fixed	Data size (refer to Table 24-58)
	1	32	U-ADDR	Variable	Unique portion of the data read value
	1	64	DATA	Variable	Data read value
Error Message	6	6	TCODE	Fixed	TCODE number = 8
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	5	5	ECODE	Fixed	Error code (refer to Table 24-57)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	Fixed	TCODE number = 13 (0xD)
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	3	3	DSZ	Fixed	Data size (refer to Table 24-58)
	1	32	F-ADDR	Variable	Full access address (leading zero (0) truncated)
	1	64	DATA	Variable	Data write value

Table 24-56. Public TCODEs Supported (continued)

Message Name	Packet Size Bits		Packet Name	Packet Type	Packet Description
	Min	Max			
Data Trace - Data Read Message w/ Sync	6	6	TCODE	Fixed	TCODE number = 14 (0xE)
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	3	3	DSZ	Fixed	Data size (refer to Table 24-58)
	1	32	F-ADDR	Variable	Full access address (leading zero (0) truncated)
	1	64	DATA	Variable	Data read valued
Watchpoint Message	6	6	TCODE	Fixed	TCODE number = 15 (0xF)
	4	4	SRC	Fixed	Source processor identifier (multiple Nexus configuration)
	4	4	WPHIT	Fixed	Number indicating watchpoint sources

Table 24-57. Error Code (ECODE) Encoding (TCODE = 8)

Error Code (ECODE)	Description
00000	Reserved
00001	Reserved
00010	Data Trace overrun
00011	Reserved
00100	Reserved
00101	Invalid access opcode (Nexus Register unimplemented)
00110	Watchpoint overrun
00111	Reserved
01000	Data Trace and Watchpoint overrun
01001–11111	Reserved

Table 24-58. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
000	Byte
001	Halfword (2 bytes)
010	Word (4 bytes)
011	Doubleword (8 bytes)
100–111	Reserved

24.14.5.1 Data Trace

This section deals with the data trace mechanism supported by the NXDM module. Data trace is implemented via data write messaging (DWM) and data read messaging (DRM).

24.14.5.2 Data Trace Messaging (DTM)

NXDM data trace messaging is accomplished by snooping the NXDM data bus, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXDM module traces all data access that meet the selected range and attributes.

NOTE

Data trace is ONLY performed on DMA accesses to the system bus.

24.14.5.3 DTM Message Formats

The NXDM block supports five types of DTM Messages — data write, data read, data write synchronization, data read synchronization and error messages.

24.14.5.3.1 Data Write and Data Read Messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. Data write message and data read message information is messaged out in the following format:

Figure 24-66. Data Write/Read Message Format

24.14.5.3.2 DTM Overflow Error Messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. After it is emptied, an error message will be queued. The error encoding will indicate which types of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message will incorporate the data trace only error encoding (00010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message will incorporate error encoding (01000).

Error information is messaged out in the following format:

Figure 24-67. Error Message Format

24.14.5.3.3 Data Trace Synchronization Messages

A data trace write/read w/ sync. message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (refer to [Table 24-59](#)):

- Initial data trace message upon exit from system reset or whenever data trace is enabled will be a synchronization message.
- Upon returning from a low power state, the first data trace message will be a synchronization message.
- Upon returning from debug mode, the first data trace message will be a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message will be a synchronization message.
- After the periodic data trace counter has expired indicating 255 *without-sync* data trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In ($\overline{\text{EVTI}}$) pin, the first data trace message will be a synchronization message if the eic bits of the dc register have enabled this feature.
- Upon data trace write/read after the previous dtm message was lost due to an attempted access to a secure memory location.
- Upon data trace write/read after the previous dtm message was lost due to a collision entering the fifo between the dtm message and any of the following: error message, or watchpoint message.

Data trace synchronization messages provide the full address (without leading zeros) and insure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read w/ sync. messages is as follows:

Figure 24-68. Data Write/Read w/ Sync Message Format

Exception conditions that result in data trace synchronization are summarized in [Table 24-59.](#), “Data Trace Exception Summary.”

Table 24-59. Data Trace Exception Summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (JCOMP), queue pointers, counters, state machines, and registers within the NXDM module are reset. If data trace is enabled, the first data trace message is a data write/read w/ sync. message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message will be converted to a data write/read w/ sync. message.
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. After it is emptied, an error message will be queued. The error encoding will indicate which types of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a data write/read w/ sync. message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read w/ sync. message is queued. The periodic data trace message counter then resets.
Event In	If the nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data trace write/read w/ sync. message upon the next data write/read (if data trace is enabled and the eic bits of the dc register have enabled this feature).
Attempted Access to Secure Memory	Any attempted read or write to secure memory locations will temporarily disable data trace & cause the corresponding DTM to be lost. A subsequent read/write will queue a data trace read/write w/ sync. message.
Collision Priority	All messages have the following priority: Error -> WPM -> DTM. A DTM message which attempts to enter the queue at the same time as an error message, or watchpoint message will be lost. A subsequent read/write will queue a data trace read/write w/ sync. message.

24.14.5.4 DTM Operation

24.14.5.4.1 Enabling Data Trace Messaging

Data trace messaging can be enabled in one of two ways.

- Setting the DC1[TM] field to enable data trace
- Using the WT[DTS] field to enable data trace on watchpoint hits

24.14.5.4.2 DTM Queueing

NXDM implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

NOTE

If multiple trace messages need to be queued at the same time, watchpoint messages will have the highest priority (WPM -> DTM).

24.14.5.4.3 Relative Addressing

The relative address feature is compliant with IEEE®-ISTO Nexus 5001-2003 and is designed to reduce the number of bits transmitted for addresses of data trace messages. Relative addressing is the same as described for the NZ6C3 in [Section 24.11.12.3.2, “Relative Addressing.”](#)

24.14.5.4.4 Data Trace Windowing

Data write/read messages are enabled via the RWT1(2) field in the data trace control register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA registers and by the RC1(2) field in the DTC. All eDMA initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

24.14.5.4.5 System Bus Cycle Special Cases

Table 24-60. System Bus Cycle Special Cases

Special Case	Action
System bus cycle aborted (DABORT asserted)	Cycle ignored
System bus cycle with data error	Data Trace Message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

24.14.5.5 Data Trace Timing Diagrams (8 MDO configuration)

Data trace timing for the NXDM is the same as for the NZ6C3. Refer to [Section 24.11.13.4, “Data Trace Timing Diagrams \(Eight MDO Configuration\).”](#)

24.14.6 Watchpoint Support

The NXDM module provides watchpoint messaging via the auxiliary pins, as defined by IEEE®-ISTO 5001-2003.

Watchpoint messages can be generated using the NXDM defined internal watchpoints.

24.14.6.1 Watchpoint Messaging

Enabling watchpoint messaging is accomplished by setting the watchpoint messaging enable bit, DC1[WEN]. Using the BWC1 and BWC2 registers, two independently controlled internal watchpoints can be initialized. When a DMA access address matches on BWA1 or BWA2, a watchpoint message will be transmitted.

The Nexus module provides watchpoint messaging using the TCODE. When either of the two possible watchpoint sources asserts, a message will be sent to the queue to be messaged out. This message indicates the watchpoint number.

Figure 24-69. Watchpoint Message Format

Table 24-61. Watchpoint Source Description

Watchpoint Source (4 bits)	Watchpoint Description
XXX1	Reserved
XX1X	Reserved
X1XX	Internal Watchpoint #1 (BWA1 match)
1XXX	Internal Watchpoint #2 (BWA2 match)

24.14.6.2 Watchpoint Error Message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. After it is emptied, an error message will be queued. The error encoding will indicate which types of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message will incorporate the watchpoint only error encoding (00110). If a data trace message also attempts to enter the queue while it is being emptied, the error message will incorporate error encoding (01000).

Error information is messaged out in the following format (refer to [Figure 24-70](#)).

Figure 24-70. Error Message Format

24.15 Document Revision History

Table 24-62. Changes Between MPC5565RM Revisions 0.1 and 1

<p>To the table “Event Code Encoding (TCODE = 33), Table 24-22, made the following changes:</p> <ul style="list-style-type: none"> • Added the row “Disabling Program Trace” • Added footnote: “The device enters Low Power Mode when the Nexus stall mode is enabled (NZ6C3_DC1[OVC]=0b011) and a trace message is in danger of over-flowing the Nexus queue.”
<p>Made this change from Ownership Trace Messaging (OTM) section:</p> <ul style="list-style-type: none"> • Removed: “There are two conditions which will cause an ownership trace message. <ol style="list-style-type: none"> 1. When new information is updated in the OTR register or process ID register by the e200z6 processor, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. 2. When the periodic (255) OTM message counter expires (after 255 queued messages without an OTM), an OTM will be sent. The data will be sent from either the latched OTR data or the latched process ID data. This allows processors using virtual memory to be regularly updated with the latest process ID.” • Added: “There is one condition which will cause an ownership trace message: When new information is updated in the OTR register or process ID register by the e200z6 processor, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. “
<p>Expanded a sentence in the Resource Full Messages section:</p> <ul style="list-style-type: none"> • From: The resource full message is generated when the internal branch/predicate history buffer is full. • To: The resource full message is generated when the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows.
<p>In Figure 24-32, “Resource Full Message Format” changed name of field from HIST to RDATA.</p>

¹ The registers mapped in the ECSM module (0xFFFF4_0014–0xFFFF4_001F) can control and configure the software watchdog timer in the standard Freescale ECSM block incorporated in the device. The e200z6 core also provides this functionality and is the preferred method for watchdog implementation. To optimize code portability to other members of the MPC55XX family, use of the watchdog registers in the ECSM is not recommended.

Appendix B Calibration

B.1 Overview

The MPC5500 family of microcontrollers includes various specialized features to support automotive calibration. Many of these calibration features are not available to the final application software, and some MPC5500 devices support calibration signals that are not available in the standard 208, 324, and 416 BGA packages. Special calibration assembled devices with increased signal bond-out provide full access to all calibration resources for all MPC5500 variants.

Calibration hardware that uses the calibration assembled devices is detailed in [Figure B-1](#). Freescale-produced VertiCal bases use the calibration-assembled MPC5500 device mounted on a small circuit board with a footprint which is compatible with that of the production BGA packaged MPC5500 device. A 156-way VertiCal connector on the top-side of the VertiCal base allows you to attach VertiCal compliant top-board hardware. Various types of top-board hardware to support calibration and debug are available from Freescale and commercial companies.

The VertiCal connector standard defines the set of signals used to communicate between the microcontroller on the VertiCal base board and the attached calibration development tools, called top-boards. Signal availability or sourcing for the VertiCal connector differs depending on the MPC5500 device used.

The calibration system is illustrated in [Figure B-1](#) and the VertiCal Base is illustrated in [Figure B-2](#).

Figure B-1. Calibration Assembly

Figure B-2. VertiCal Base

B.2 Calibration Bus

The calibration bus is made up of address bus, data bus, bus control and clock signals. The calibration bus is used by tools that include memory for calibration data or other code in development. Refer to [Table B-1](#) for calibration bus signals. A 16-bit data bus and 19-bit address bus gives a basic addressing range of 1 MB. Alternatively, the maximum memory addressable using just one chip select is four MB. Refer to [Table B-2](#).

The VertiCal connector supports up to 4 chip select signals, although the actual number of chip selects available depends on the device and package. Use the CAL_ \overline{CS} [0] chip select as the default calibration chip select to ensure maximum portability of calibration tools across devices. The three calibration chip select signals CAL_ \overline{CS} [0, 2:3] are configured and function like the external chip select signals \overline{CS} [0:3], except the calibration chip selects have a higher priority in address decoding than the external chip selects, \overline{CS} [0:3]. Refer to [Section B.7, “Application Information,”](#) for application information on the number of calibration chip selects.

The CAL_ \overline{CS} [0:3] chip selects have multiplexed signal functions to provide additional addressing bits that allows the flexibility of increasing the addressing range or the number of chip selects. Devices that support less than four calibration chip selects can extend the contiguous calibration addressing range by omitting chip selects starting from \overline{CS} [1]. For this reason \overline{CS} [1] is the only chip select pin not implemented on the MPC5565 device.

The calibration functionality provides a calibration bus with pads that are in addition to the pads for the 416 pin package part. Therefore, the calibration functionality does not use any I/O available in the 208, 324, and 416 pin production packages for a calibration bus interface.

The P/A/G column in the following table differentiates each signal function that is multiplexed to the same pin assignment. The P/A/G value is set in the PA field of the SIU_PCR registers and determines which multiplexed signal function controls the pin. For more information on how to set the PA field, read the Signals Chapter.

Table B-1. MPC5565 Calibration Bus Signals

496 VertiCal Signal Name	Signal Function	Signal Name	P/A/G
Calibration Bus			
CAL_ \overline{CS} [0]	Calibration chip select 0	CAL_ \overline{CS} [0]	P
CAL_ \overline{CS} [2:3]	Calibration chip select 2-3 Calibration address	CAL_ \overline{CS} [2:3] CAL_ADDR[10:11]	P A
CAL_ADDR[12:30]	Calibration address bus	CAL_ADDR[12:30]	P
CAL_DATA[0:15]	Calibration data bus	CAL_DATA[0:15]	P
CAL_RD_ \overline{WR}	Calibration read/write	CAL_RD_ \overline{WR}	P
CAL_ $\overline{WE/BE}$ [0:1]	Calibration write/byte enable	CAL_ $\overline{WE/BE}$ [0:1]	P
CAL_ \overline{OE}	Calibration output enable	CAL_ \overline{OE}	P
CAL_ \overline{TS}	Calibration transfer start	CAL_ \overline{TS}	P

CLKOUT	System Clock Output	CLKOUT	P

B.3 Device-Specific Information

The various address bus, data bus and bus control signals are sourced from different signals depending on the MPC5500 device used, as detailed in the following sections.

B.3.1 MPC5565 Calibration Bus Implementation

The MPC5565 device has a set of external bus signals that are only used by the calibration bus. These device signals are prefixed by CAL, and their usage does not affect the usage modes and electrical loading on the equivalent signals for the EBI.

B.4 Signals and Pads

The following sections detail the signal descriptions for the calibration bus.

B.4.1 CAL_ \overline{CS} [0, 2:3] — Calibration Chip Selects 0, 2 and 3

CAL_ \overline{CS} [*n*] is asserted by the master to indicate that this transaction is targeted for a particular calibration memory bank.

The calibration chip selects are driven by the EBI. CAL_ \overline{CS} [*n*] is driven in the same clock as the assertion of \overline{TS} and valid address, and is kept valid until the cycle is terminated. Bus timing is identical to standard EBI timing.

B.4.1.1 Number of Chip Selects and Maximum Memory Size

The trade-off between calibration chip selects and address lines is the same as the trade-off between non-calibration chip selects and address lines for the 324 pin package.

Table B-2. Maximum Memory Size According to Calibration Chip Selects

	Maximum Memory Allocated for Calibration		
	Device 0	Device 2	Device 3
CAL_ \overline{CS} [0] only	4 MB	—	—
CAL_ \overline{CS} [0] and CAL_ \overline{CS} [2]	2 MB	2 MB	—
CAL_ \overline{CS} [0] and CAL_ \overline{CS} [2:3]	1 MB	1 MB	1 MB

B.4.2 Pad Ring

This section provides a list of the calibration pins and associated pad configuration registers (PCRs), including links to the detailed PCR information for each pin or pin group.

Refer to [Table B-1](#) for device signal names.

The drive strength of the calibration pins is configured in the PCR registers. In some cases, multiple pads have their drive strengths controlled by one PCR by grouping the pins:

- CAL_ADDR[12:30]
- CAL_DATA[0:15]
- CAL_RD_W \overline{R} , CAL_W \overline{E} /BE[0:1], CAL_O \overline{E} , CAL_T \overline{S}

The SIU_PCR registers control whether the CAL_C \overline{S} [2:3] pins are used for CAL_C \overline{S} [2:3] or for CAL_ADDR[10:11]. Refer to [Table B-2](#) for the pin assignments. Selecting between CAL_C \overline{S} [2:3] and CAL_ADDR[10:11] allows you to maximize the amount of calibration memory size by limiting the number of calibration chip selects to C \overline{S} [0]. Refer to [Section B.4.1.1, “Number of Chip Selects and Maximum Memory Size.”](#)

B.4.3 CLKOUT

CLKOUT is supplied by the clock control block, not the EBI. Nevertheless, the same CLKOUT is used for both the non-calibration and calibration bus.

A drawback of having just one CLKOUT is that while the difference in board timing can be compensated by the adjustment in the drive strength, the CLKOUT timing, and hence the timing of the non-calibration bus, can have minor differences with a calibration tool from the production package.

B.5 Power Supplies

The signals that make up the calibration bus have their own power supply segment (V_{DDE12}). The V_{DDE12} power supply balls are not connected to any other power supply segment from the standard package ball-out but are routed on the VertiCal base to pins on the VertiCal connector. The VertiCal top board must provide voltage to the V_{DDE12} power supply pins to power up the calibration bus. The VertiCal top board can derive a 3.3 V supply by regulating down the vehicle battery voltage, connected via a connector and flying lead to the top board.

B.6 Integration Logic Functionality

The EBI connects to both the non-calibration and calibration buses. The integration logic on MPC5565 selects between the data input from both buses to the EBI.

The MPC5565 integration logic also suppresses the reflections of the outputs of the calibration bus onto the non-calibration bus. For the non-calibration bus pins that do not have a negated state to which the pins return at the end of the access, this reflection suppression is enabled by the SIU_CCR[CRSE] bit. SIU_CCR[CRSE] does not enable reflection suppression for the non-calibration bus pins that have a negated state to which the pins return at the end of an access. Those reflections always are suppressed.

Furthermore, the suppression of reflections from the non-calibration bus onto the calibration bus is not enabled by CRSE. Those reflections are also always suppressed.

Refer to [Section B.7.1, “Enabling Calibration Reflection Suppression,”](#) for when to set SIU_CCR[CRSE] or leave it in its reset negated state.

B.7 Application Information

B.7.1 Enabling Calibration Reflection Suppression

Set SIU_CCR[CRSE] to suppress reflections when calibrating. The calibration reflection suppression logic for an output that does not return to a negated state at the end of an access can introduce a small glitch on the output at the end of the access. The glitch does not interfere with the output valid or hold times. However, keep SIU_CCR[CRSE] in its reset negated state when not calibrating to prevent a glitch on the non-calibration bus outputs.

B.7.2 Communication With Development Tool Using I/O

The development tool can require some I/Os for communication between the MCU and the development tool on the VertiCal connector. Because the application can not use these pins in the 208 and 324 pin packages, they can be used for development tool use in a VertiCal connector.

B.7.3 Matching Access Delay to Internal Flash With Calibration Memory

One use of VertiCal in the Automotive environment is engine calibration. For this application, an SRAM Top Board is added onto the VertiCal connector. This allows the engine calibrator to modify settings in SRAM, possibly using the Nexus interface or even by using the SCI port or a CAN interface.

Refer to [Table 13-2](#) “Internal Flash External Emulation Mode.”

After the data is calibrated, it can be copied into the internal flash. The internal flash can be accessed faster than the calibration memory and this change in calibration data access time could change the overall system performance. To mitigate this change in system performance, the internal flash memory includes a feature that allows accesses to portions of the flash to be slowed down by adding extra wait states. This is done by multiply mapping the internal flash at different locations with different number of wait states. For example, the physical address of the flash array is 0x0000_0000 to 0x00FF_FFFF (depending on array size). That same flash data can be accessed at address 0x0100_0000 to 0x01FF_FFFF but accesses are one clock cycle slower. That same flash data can be accessed at addresses 0x0200_0000 to 0x02FF_FFFF but accesses are two clock cycles slower. This pattern is repeated through the memory map to addresses 0x1F00_0000 to 0x1FFF_FFFF where accesses are 31 clock cycles slower.

The application would use this feature by mapping the calibration data to a region of the flash memory that has access timing to match the timing of the calibration RAM used when calibrating the data. This remapping of calibration data can be achieved by either using the translation feature of the MMU or rebuilding the code with a modified link file.

B.8 Document Revision History

Table B-3. Changes Between MPC5565RM Revisions 0.1 and 1

No changes since the last release.
